Reconstitution of the Frontiers.—The foreign troops were received with different feelings by different parties in Switzerland They were welcomed as liberators by the old aristocratic cantons, which hoped that the old régime would be unconditionally restored. On the other hand they were regarded with disfavour by the cantons which the Act of Mediation had brought into existence. An aristocratic revolution broke out at Berne on Dec 24, 1813, and this example was immediately followed in the other cantons Everywhere the old Governments were restored to power; the Act of Mediation was denounced. This created oppositions and rivalries of so profound a character that war was several times on the point of breaking out between the cantons. The representatives of the Powers, among them Stratford Canning, were obliged to intervene, sometimes in a friendly way and sometimes with threats, to induce the Swiss to agree upon a new Federal Pact (Sept. 1814), which restored the old federal institutions, including the practically absolute sovereignty of the cantons; the diet was a diplomatic body with hardly any real power. At this time a great movement of liberation took place in the districts which Napoleon had detached from Switzerland, and certain of the neighbouring territories: the bishoprics of Basle, Neuchâtel, Geneva, Savoy, the Valais and Valtellina expressed a wish to form part of the Confederation. Neuchâtel recalled its prince, the king of Prussia The Treaty of Paris (May 30, 1814), which fixed the frontiers of France, left most of these districts outside that country. On Sept. 12, 1814, Neuchâtel, Geneva and the Valais were officially received into the Confederation as cantons

The final settlement of internal and external questions relating to Switzerland was undertaken by the Congress of Vienna This was done, after long discussions and a great deal of criticism, by two acts dated March 20 and 29, 1815. The first act laid down the perpetual neutrality of Switzerland, which was given its old frontiers, with the exception of Mulhouse, which remained with France, and Valtellina, which went to Austria The internal difficulties of the country were settled by the confirmation of the existing frontiers between the cantons and by a series of compromises on financial indemnities claimed by the various cantons from one another. By the second act, Switzerland received a slight accession of territory in Savoy, and its neutrality was extended to Northern Savoy.

Swiss neutrality did not, however, survive Napoleon's return. The very Powers which had just proclaimed its neutrality at once required the Confederation to enter into alliance with them, since they needed its aid in the struggle with France (May 20, 1815). The Federal troops entered Franche-Comté on July 3. When, however, the second Treaty of Paris was concluded on Nov. 20, 1815, the Swiss were not rewarded for their help as they had hoped. All they obtained was a slight rectification of their frontier on the French side, and the creation of a free zone near Geneva. These provisions were supplemented a few months later (March 16, 1816) by the Treaty of Turin, concluded with Sardinia. The frontiers of Switzerland have remained unchanged since that time.

The Restoration.—The early part of the Restoration period was characterized in Switzerland by an enthusiastic return to the political forms of the past, and at the same time by a serious economic crisis, due to the war. Swiss industry, which had for a long time been protected by the Continental blockade, now found all the markets of the Continent closed to it at the very time when it was again faced with the competition of England, especially in the textile trade. A strong Government at home and abroad would have been needed to deal with the situation; but no such Government existed. The cantons possessed and exercised the right to impose internal customs duties; but they were never able to agree upon a common customs policy. The Confederation exercised no central authority worthy of the name, and there was no spirit of solidarity among the Governments of the cantons, which were to a large extent dependent on the foreign countries with which they entertained direct relations. In particular the system of capitulations, which made the aristocracy of the cantons directly dependent on foreign countries, had again come into being on a large scale.

Switzerland was consequently obliged, under the pressure of Russian diplomacy, to become a member of the Holy Alliance on Jan. 27, 1817. Similarly it was obliged to persecute the liberal refugees who flocked into the territory of the Confederation from all the neighbouring countries. Switzerland made every effort to avoid being forced into action so contrary to the traditions of the country, but it was nevertheless compelled in 1823 to yield to the pressure of the Holy Alliance and to restrict the press.

Period of Regeneration.—The political, economic and moral influences described above made themselves felt in the revision of the constitutions of several cantons—Schaffhausen, Appenzell, Lucerne, Vaud, etc.—which was undertaken in 1828 and 1829. The movement gained in strength under the influence of the Revolution in France, and between 1830 and 1833 about ten cantons, including the largest, Zürich, Lucerne and Berne, revised their constitutions in the sense of greater liberalism.

The liberal movement of 1830, which has been called the period of regeneration as opposed to the restoration, had to face obstacles both in the cantonal and in the Federal sphere. At Neuchâtel the revolution which broke out against the government of the prince (the king of Prussia), was a failure. In Schwyz, civil war and the division of the canton into two parts were only averted by Federal mediation. Disturbances accompanied by loss of life broke out in the canton of Basle, and on Aug. 17, 1833, the diet decided to separate the canton into two half-cantons, one urban and the other rural. The liberals were anxious to obtain the revision of the Federal Pact. Taking advantage of the majority which they possessed in the diet, they obtained a decision to this effect on July 17, 1832.

The Young Europe movement, which had its centre in Switzerland, the intrigues of Mazzini, the meeting of the German liberals at Berne in 1834, the assassination of the German spy Lessing in 1835, the arrest of the French *agent provocateur* Conseil in 1836, led to a series of diplomatic difficulties for Switzerland. The most serious incident, which very nearly involved the Confederation in a war with France, was that which arose in 1838 out of the presence in Thurgau and the activities of Prince Louis Napoleon Bonaparte, afterwards Napoleon III.

The Sonderbund War.—Within the Confederation itself the struggle for the revision of the Federal Pact soon assumed a character of such violence as to presage the civil war which in fact subsequently broke out. On March 17, 1832, the liberal cantons concluded a sort of alliance among themselves, known as the "Concordat of the Seven" (*Siebener Concordat*), by which they mutually guaranteed their constitutions. In November the conservative cantons concluded a similar alliance (League of Sarnen). These alliances were not confessional in character, and included both Protestant and Catholic cantons. The situation, however, was altered by the Articles of Baden, adopted by the liberal cantons on Jan. 20, 1834; they contained a programme of ecclesiastical reform, and transformed the struggle for the revision of the Constitution into a religious quarrel.

The Articles of Baden were condemned by the ecclesiastical authorities on May 17, 1835, but were enforced with vigour and even with brutality by certain cantons. On Jan. 20, 1841, the canton of Aargau suppressed the monasteries, thus violating the Pact, which guaranteed them. On May 1, 1841, the Catholics returned to power in Lucerne, and on Oct. 24, 1844, they called in the Jesuits to teach in the cantonal high-school. This irritated the liberals of the cantons of Berne and Aargau, which organized armed bands (*corps francs*) who on two occasions invaded the territory of Lucerne. Seven Catholic cantons—Lucerne, Uri, Schwyz, Unterwalden, Zug, Fribourg and Valais—replied by concluding, on Dec. 11, 1845, a separate and secret alliance known as the *Sonderbund*. On July 20, 1847, the diet declared by a majority that the *Sonderbund* was contrary to the Constitution, and ordered its dissolution. The seven cantons refused to obey, and the Genevese General G. H. Dufour marched against them at the head of the Federal army and defeated them after a short campaign in Nov. 1847. He thus averted an intervention by the Powers which was being planned by Metternich and Guizot, although the scheme was opposed by Lord Palmerston.

The Federal State.—The Federal Constitution of 1848, while respecting the sovereignty of the cantons, gave the Confederation wide powers, particularly in the economic sphere. Executive power was placed in the hands of a Federal Council of seven members elected by Parliament for three years and in practice almost always re-elected. The legislative authority lay in two chambers, one representing the nation as a whole and the other the cantons. It will be seen from this that the authors of the Swiss Constitution—Kern of Thurgau, Druey of Vaud and James Fazy of Geneva—drew their inspiration largely from the American model. The headquarters of the Federal authorities, which had up till then been moved every two years, were fixed at Berne. The most novel feature of the new Constitution was the ample provision made for its amendment. It was the immutable character of the Pact of 1815 which had led to civil war, and the authors of the 1848 Constitution took pains to avoid falling into the same error. The new Federal authorities, in which the most moderate elements of the liberal party had a majority, at once set to work. The postal and telegraphic systems, the customs, the currency and weights and measures were unified in succession. The act of 1852 dealing with railways was the most important legislative measure, and once more exacerbated the rivalry between the various cantons and districts, more particularly Berne and Zürich. This did not, however, prevent rapid progress in the building of railways.

The new Confederation was at once faced with serious decisions on foreign policy. In 1848 Sardinia offered Switzerland its alliance against Austria; but such an offer was contrary to the perpetual neutrality of Switzerland, and it was rejected. In the years which followed the great crisis of 1848 a large number of political refugees established themselves in Switzerland, involving that country in disputes with most of the neighbouring Powers—France, Sardinia, Austria and Germany. In 1848 Neuchâtel (*q.v.*) had proclaimed a republic. In 1856 a revolution attempted to restore the power of the prince. War with Prussia was narrowly averted by the mediation of Napoleon III., to whom the Swiss cause was represented by the embassy of General Dufour to Paris. The king of Prussia was finally persuaded to renounce his rights, save the title—which his successor also subsequently dropped.

The foreign policy of the Confederation then began to take other directions. In 1864 the International Red-Cross Committee was founded at Geneva on the initiative of Henry Dunant, Gustave Moynier and a certain number of Genevese citizens. The result of this was to give a humanitarian bias to Swiss neutrality in all subsequent wars, and to prepare the way for the international functions which the Confederation was later to perform. The first international office, dealing with telegraphs, was founded at Berne in 1865; and in 1872 Switzerland was the scene of the first attempt at international arbitration in the *Alabama* affair between Great Britain and the United States. (*See* Alabama Arbitration.)

In the meantime there had been a recrudescence of internal political dissension. In 1866 a series of amendments to the Federal Constitution were rejected by popular vote, with the exception of one which conferred equal rights of citizenship on Jews. In the following years a number of cantons, including Zürich, intro-

duced into their constitution the principle of direct democracy, or in other words the right of the nation to have laws adopted by the legislative bodies submitted to it for approval.

The two great international events of 1870, the Vatican Council and the Franco-Prussian War, led to a widespread movement in Switzerland in favour of the revision of the Constitution. The former was held to show the necessity for the State to protect itself against the excessive power of the Church, and the second the need for the reorganization of the army. A first revision scheme was rejected in 1872 by a Federalist coalition consisting of the Catholic cantons and the French-speaking cantons Two years later, however, a second scheme, which met the objections of the French-speaking cantons and included stronger anti-Catholic provisions, was adopted by the nation

Direct Democracy.—The 1874 Constitution, which remains in force at the present day (1929), gives considerably wider powers to the Federal State, especially in military matters, and introduces direct democracy in Federal affairs in the form of the optional referendum on legislation.

Except for a revolution in the canton of Ticino in 1890, in which the Catholic Government was forcibly overthrown by its radical opponents, the Swiss internal political situation has since that time been dominated by economic preoccupations and by a tendency towards centralization. Throughout that period the radical party has had a majority in the Federal Assembly, and this fact has tended more and more to promote the transfer of the powers of the cantons on economic questions to the Confederation, especially since 1891, when the right of popular initiative on constitutional questions was introduced. To mention only the principal instances, the monopoly of spirits was handed over to the Confederation in 1887, the power to enact legislation on social insurance in 1890, and the monopoly of issuing bank notes in 1891. In 1898 the nation declared in favour of the purchase of the railways by the Confederation and the unification of civil and penal law. The National Bank was set up in 1906; in 1907 legislation was adopted increasing the powers of the Confederation in military affairs, and the Federal chambers adopted the new civil code; in 1908 the nation decided to prohibit the manufacture and consumption of absinthe; in 1912 it voted for the Insurance Act, provision for which was made by the Constitution, but the first draft for which had been rejected in 1900 because it was considered to confer too much power on the State

In the economic sphere, the period was characterized by a great increase in industrial and commercial activity due partly to the construction of railways and partly to the introduction of a protectionist system The St Gotthard tunnel was constructed in 1880 and the line opened in 1882; the Simplon tunnel was opened in 1906 and the Loetschberg tunnel in 1913 An immense number of mountain railways were also built. A new customs tariff was adopted in 1884, and was modified not long after in the direction of increased protection Another new customs tariff was adopted in 1891, with results of a twofold character; in Switzerland itself it aroused the covetous instincts of some of the cantons, and a demand was put forward by popular initiative for the distribution of part of the customs receipts among the cantons This initiative, which was known as the *Beutezug* or plundering expedition, was rejected by the nation in 1894 In the sphere of foreign politics, the raising of the tariff led to a customs war with France (1893–95), in which the advantage remained to a certain extent with Switzerland

Switzerland has been involved in three other international disputes, none of which have, however, been of great importance. The first was the Wohlgemuth affair in 1889, which arose out of the arrest on Swiss territory of an agent of the German political police. The second was the Silvestrelli affair in 1902. The dispute originated from the publication of anarchist articles in an Italian newspaper appearing in Switzerland; it led to the temporary breach of diplomatic relations with Italy. The third dispute arose with Germany in connection with the St. Gotthard (Railway) Convention in 1909. The Swiss considered that the German Government had on that occasion abused its superior diplomatic position, and a large section of public opinion was violently opposed to the ratification of the Convention. The Chambers, however, voted in favour of ratification, and a popular initiative was therefore instituted which led after the war, in 1921, to the introduction of an article into the Constitution according to which the ratification of long-term international treaties might optionally be submitted to a popular referendum

The World War.—A national exhibition, which bore witness to the prosperity and to the industrial development of Switzerland, was being held at Berne in 1914 when the war broke out. The Federal Council at once took steps to safeguard the practical neutrality of Switzerland both from the political and the economic point of view. The army was mobilized to guard the frontiers, and the Federal Assembly appointed Colonel Ulrich Wille of Zürich as commander-in-chief. The Federal Council obtained from Parliament powers which, though perhaps not strictly compatible with the constitution, were required by the circumstances. It proceeded to take steps to obtain sufficient supplies of wheat and coal for the Confederation.

The war was a period of trial for the Swiss from the economic, political and moral point of view. It was found impossible, notwithstanding treaty obligations, to maintain complete economic neutrality. Switzerland was over-populated and over-industrialized in proportion to its resources, and was largely dependent on foreign countries for its supplies of foodstuffs and raw materials The Allies refused to supply foodstuffs unless Switzerland ceased to trade with Germany, while Germany threatened, if Switzerland did so, to withhold the necessary coal supplies The situation became exceedingly critical after Italy came into the war in May 1915, and still more when the United States also entered the field in April 1917. Although in one way the industries of Switzerland made the position of the country more difficult, they nevertheless helped to preserve its existence; for all the belligerent States were equally interested in keeping the Swiss factories at work A *modus vivendi* with Germany was devised in 1915 by the institution of the *Treuhandstelle* at Zurich, and with the Allies by the creation of the S S S (*Société suisse de surveillance économique*) These bodies gave each side a guarantee that the goods which it exported to Switzerland would not be re-exported, and in this way Switzerland was enabled, however inadequately, to obtain supplies.

Financially the war cost the Confederation dear. The whole or part of the army had to be kept under arms throughout the war, and the total expense of this amounted to 1,220 million francs, or nearly Fr. 400 per head of the population The Swiss nation was therefore asked in 1915 to vote a Federal war tax—the first direct tax to be levied by the Confederation—and a similar tax was voted again in 1919 By this means Switzerland was able to avoid the inflation of its currency and the depreciation of the exchange

From the political point of view, the Confederation endeavoured to practice the most scrupulous neutrality between the belligerents Its task was rendered difficult by the fact that public opinion in Switzerland was neither neutral nor united. French-speaking Switzerland was violently anti-German and pro-Ally, and in these districts the Federal Council was severely criticized for not having protested against the violation of Belgian neutrality in 1914 Feeling ran less high in German-speaking Switzerland, but was rather in favour of Germany, to which country Switzerland was bound by a number of economic and cultural interests This explains, though it does not justify, the fact that pro-German sympathies were manifested, against the will of the Government, in high political and military circles in the Confederation. The affair of the colonels in 1916, when information was supplied by the Staff to foreign military attachés, and the Hoffmann affair in 1917 (an attempt to negotiate peace between Germany and Russia) were not, it is true, actually breaches of neutrality, but they nevertheless aroused the greatest indignation among the public, which insisted that the persons involved should be punished. On the resignation of the Federal councillor Hoffmann, Gustave Ador (*q.v.*), chairman of the International Red Cross Committee, became a member of the Federal Council M. Ador stood for all that was best and most constructive in the work of Switzerland in the international sphere—for active charitable work, for the relief of prisoners of war and of the men in internment camps

For the population of Switzerland, the war years were years of privation on the material side, and on the moral side of constant agitation without definite aim, especially in the German-speaking districts. It is not surprising that symptoms of exhaustion and moral strain should have appeared; and as a result there broke out in Switzerland a general strike of a political character as an echo of the German Revolution. This necessitated the mobilization of the army on the day of the Armistice (Nov. 11, 1918); and a large number of soldiers lost their lives as a result of influenza.

Peace, and the Post-War Period.—As the Swiss Confederation had not taken part in the war, it was not able to participate in drawing up the Treaty of Peace. It was, however, represented at the Peace Conference by a number of official delegates, and its interests were in several respects affected by the Treaty of Versailles. The Federal Council devoted special efforts to obtaining recognition of the perpetual neutrality of Switzerland within the framework of the League of Nations. The city of Geneva was selected as the headquarters of the League. New international rules for the navigation of the Rhine were drawn up, and the Gotthard Convention of 1909 which had aroused such strong feeling in Switzerland before the war was repealed.

The population of Vorarlberg, an Austrian district adjoining Switzerland on the east, expressed by a large majority its desire for union with Switzerland, but was unable to succeed in having its claim recognized by the Treaty of Saint-Germain.

From the international point of view, the post-war period was one of great activity for Switzerland. On Feb. 13, 1920 the Federal Council succeeded in obtaining from the Council of the League of Nations, which was then meeting in London, recognition of the fact that the maintenance of the perpetual neutrality of Switzerland was not incompatible with the Covenant of the League. As a result of that decision, after a hotly contested electoral campaign, the Swiss nation decided on May 16, by a small majority, to enter the League of Nations. From that time the Swiss delegation, headed by M. Motta, played a useful part in the successive Assemblies of the League.

The Principality of Liechtenstein, a district with 13,000 inhabitants which had previously maintained a customs union with Austria, adopted the Swiss currency in 1920, and on Nov. 10 of that year concluded a number of economic agreements with that country. On March 29, 1923 a customs union was concluded. After 1920 the representation of Liechtenstein in foreign countries was undertaken by Switzerland.

The representative of Soviet Russia at the Lausanne Conference, which was held for the negotiation of peace with Turkey, was assassinated on May 10, 1923, and this led to a diplomatic dispute between Switzerland and the Soviet Government and the breaking off of relations. The situation between the two countries continued to be extremely strained until the conclusion of the Berlin agreement on April 14, 1927.

The zones dispute arose out of the denunciation by France in 1918 of the régime of the free tariff zones created about Geneva by the treaties of 1815. A convention concluded between Switzerland and France on Aug. 7, 1921 was rejected by a large majority by a popular vote on Feb. 18, 1923. France unilaterally abolished the zones régime on Nov. 11, 1923, but an arbitration compromise was concluded by the two Governments on Oct. 30, 1924. The French senate refused to ratify this compromise agreement, conditioning its acceptance on Switzerland's abandonment of the neutrality of the Haute Savoie (to which France attaches strategic importance). Switzerland agreed in 1927 to hand over the document of the abandonment in exchange for the French ratification. The French senate acted in March, 1928, and ratifications were exchanged a few days later.

Switzerland signed the optional clause of the rules of the Permanent Court of International Justice, and concluded arbitration treaties with 19 countries, in most cases without any reservation.

The internal history of Switzerland in the years immediately following the war, as in the corresponding period of the Restoration, was characterized by a grave economic crisis. There was at first a short period of prosperity, during which the eight hour day was introduced in factories (Jan. 1920). Soon, however, the general European economic crisis spread to Switzerland, where it was aggravated by a high exchange rate. In 1922 the number of unemployed was 130,000; these, together with their families, amounted to nearly one-fifth of the total population. Various remedies, including protection, were tried without success, and considerable financial sacrifices were necessary on the part of the community to provide relief for the unemployed. The idea of a capital levy was mooted; a proposal to that effect was put forward by the parties of the extreme Left, but was rejected by an enormous majority by a popular vote on Dec. 3, 1922. Since that time there has been a great improvement in the situation both from the economic and social points of view. (W. Ma.)

Bibliography.—*La Bibliographie Nationale Suisse*, also in German, *Bibliographie der schweizerischen Landeskunde*, a series of detached parts, each complete in itself, published by the *Centralkommission für schweizerischen Landeskunde* (Berne, 1893, etc.) gives lists of books on every subject relating to Switzerland. *See* also F. C. Lanchamp, *Bibliographie Générale de la Suisse* (1922, etc.). Among older descriptions of Switzerland may be mentioned those of A. von Bonstetten (1479), C. Türst (1495), S. Münster (1544), J. Stumpf (1548), J. Simber, (1574), M. Merian (1642), J. J. Scheuchzer (1723), G. S. Gruner (1760), P. F. D. de Zurlauben (1777) and W. Coxe (1779). H. Brunner, *Die Schweiz* (2 vols., Neuchâtel, 1909), gives a complete modern account, together with the *Dictionnaire géographique de la Suisse* (Neuchâtel, 1902, etc.) and the *Dictionnaire historique et biographique de la Suisse* (Neuchâtel, 1921, etc.), both also in German. See *La Suisse au XIX*^{me} *siècle* (edit. P. Seippel, 3 vols., Lausanne, 1898–1901) and P. Cleyet, *La Suisse au XX*^{me} *siècle* (1908). For statistics, *see* the *Official Census* of 1900 (Berne, 3 vols., 1904–07), as well as the *Statistisches Jahrbuch der Schweiz* (1891, etc.), especially the volume for 1897, *Atlas graphique et statistique de la Suisse* and the *Zeitschrift für schweizerische Statistik* (Berne, 1865, four times, yearly).

Languages: J. Zimmerli, *Die deutsch-französische Sprachgrenze in der Schweiz* (3 vols., Basle and Geneva, 1891–99); for Swiss-German dialects, F. Staub and L. Tobler, *Schweizerisches Idiotikon* (Frauenfeld, 1881, etc.); L. Gaudrat, *Glossaire des patois de la Suisse romande* (Neuchâtel, 1924, etc.); for one branch of the Ladin dialect, Z. and E. Pallioppi, *Dizionari dels idioms romauntschs d'Engiadina* (Samaden, 1895); and for extracts of the Romonsch or Ladin literature, C. Decurtins, *Rätoromanische Chrestomathie* (8 vols., Erlangen, 1894–1907). *See* also T. Gartner, *Ladinische Wörter aus dem Dolomitentälern* (1923) and other works in the series of *Beiträge zur Zeitschrift für Romänische Philologie* (Halle), and the historical survey by H. Weilenmann, *Die Vielsprachige Schweiz* (Basle, 1925).

Education: *See* the official *Jahrbuch für Unterrichtswesen in der Schweiz* (Zürich, 1894, etc.), and the annual *L'Éducation en Suisse* (Geneva, 1904, etc.). For the Swiss Polytechnic school at Zürich, *see* W. Oechsli, *Geschichte der Gründung des Polytechnicums* (Frauenfeld, 1905). *See* also Education.

Economics, Trade and Commerce: *See* N. Reichesberg, *Handwörterbuch der Schweiz, Volkswirthschaft, Socialpolitik und Verwaltung* (Berne, 1903, etc.); but by far the most scholarly and up-to-date work on the economic structure is *Volkswirthschaft Arbeitsrecht und Sozialversicherung der Schweiz* (Einsiedeln, 1925); also in French, published by the Federal Government, with complete bibliographies. *See* also H. D. Lloyd, *The Swiss Democracy* (1908), R. C. Brook, *Government and Politics of Switzerland* (1918). A trustworthy work of moderate size in T. Gerring and R. Hotz, *Economie politique de la Suisse* (Zürich, 1903, trans. from a German work issued in 1902; the German only has the detailed bibliography). A full technical description of some of the chief industrial establishments is given in *Die industrielle und Kommerzielle Schweiz bei Eintritt ins XX. Jahrhundert* (Zürich, 1900, etc.); B. de Cérenville, *Le Système continental et la Suisse*, 1803–13 (Lausanne, 1906), treats of an interesting period in Swiss commercial history; W. E. Rappard, *La Révolution industrielle et les origines de la protection légale du Travail en Suisse* (Berne, 1914) has a full bibliography on all parts of the economic and social life of Switzerland from 1750. I. Williams has translated and edited *The Swiss Civil Code* (1925); for Swiss mercantile law, *see* A. Curti, *Schweizerisches Handelsrecht* (Zürich, 1903). For financial matters, *see* the *Finanz Jahrbuch* (Berne, 1899, etc.); G. Schanz, *Die Steuern der Schweiz* (5 vols., Stuttgart, 1890); J. Steiger, *Der Finanzhaushalt der Schweiz* (4 vols., Berne, 1916–19). L. Coraggioni, *Münzgeschichte der Schweiz* (Geneva, 1896), is the chief authority on Swiss numismatics.

All the great churches of Switzerland have been made the subject of monographs; *e.g.*, the Münster at Berne, by B. Haendcke and V. Muller (Berne, 1894); Lausanne, by E. Dupraz (Lausanne, 1906). *See* also E. G. Gladbach, *Die Holz-Architektur der Schweiz* (2nd ed., Leipzig, 1885), and J. Hunziker, *Das Schweizerhaus* (4 vols., Aarau, 1900–07). The biographies of Swiss artists are summarized in the *Schweizerisches Künstler-Lexikon* (Frauenfeld, 1902, etc.). The Swiss Renaissance is

dealt with by G. Schneerli, *Renaissance in der Schweiz* (Munich, 1896), and the more modern Swiss painters by J. H. Heer, *Die schweiz. Malerei des XIX. Jahrhunderts* (Leipzig, 1905).

History. The collection *Amtliche Sammlung der altern eidgenössischen Abschiede* (32 vols, 1858–1905) contains all the recesses of the diet, etc., from 1245 to 1848. A series of selected extracts from chroniclers, documents etc., is given in W. Oechsli, *Quellenbuch zur Schweizergeschichte* (2 vols., 2nd ed. of vol. i. 1901; 1st ed. of vol. ii., Zurich, 1893). The text of all the Federal Constitutions from 1798 onwards are collected in S. Kaiser and J. Strickler, *Geschichte und Texte der Bundesverfassungen der Schweiz. Eidgenossenschaft von 1798 bis zum Gegenwart* (Berne, 1901). The texts of the early alliances (1291–1513) are reprinted in J. von Ah, *Die Bundesbriefe der alten Eidgenossen* (Einsiedeln, 1891); a commentary on the Federal Constitutions from 1291 is furnished by C. Hilty, *Die Bundesverfassungen der schweiz. Eidgenossenschaft* (Berne, 1891, also in French). For more recent documents and laws, *see* the *Amtliche Sammlung der Bundesgesetze* (1849, etc.) arranged and classified by P. Wolf in *Die schweizerische Bundesgesetzgebung* (2nd ed, 3 vols, Basle, 1905–08) *See* also C. Hilty, *Politisches Jahrbuch der schweizer. Eidgenossenschaft* (Berne, 1886, etc.). For general history, *see* B. van Muyden, *Historie de la nation suisse* (3 vols, Lausanne, 1896–99); J. Dierauer, *Geschichte des schweizerischen Eidgenossenschaft* (5 vols, up to 1848, Zurich, 1887–1917); W. D. McCracken, *The Rise of the Swiss Republic* (2nd ed. 1901); L Hug and R. Stead, *Switzerland* (in "Story of the Nations" Series, 1st ed., 1891; 2nd ed., rev., 1920); E. Gagliardi, *Geschichte der Schweiz* (3 vols, Zurich, 1920); W Oechsli, *History of Switzerland, 1499–1914* (trans. E. and C Paul, 1922); W. Martin, *Histoire de la Suisse* (1926); E Fueter, *Die Schweiz seit 1848* (Zurich, 1928) *See* also H Vulliéty, *La Suisse à travers les âges* (Basle and Geneva, 1901), and H. Barth, *Bibliographie der Schweizer Geschichte* (1914, etc.).

For special periods, *see* J Heierli, *Urgeschichte der Schweiz* (Zürich, 1901); F. Stahelin, *Die Schweiz in romischer Zeit* (Basle, 1927) The authentic early history of the Confederation is admirably told by W. Oechsli, *Die Anfange der schweizerischen Eidgenossenschaft* (Zurich, 1891, also in French) For the earlier mediaeval history (1273–1334) *see* J. E Kopp, *Geschichte der eidgenossischen Bunde* (5 vols, Leipzig, Lucerne and Basle, 1845–82); the mediaeval political system in relation to the empire is described by W. Oechsli, "Die Beziehungen der Schweiz," in the *Politisches Jahrbuch* (vol. v., 1890). For the pre-1798 Constitution of Switzerland, *see* J. Simber, *De Helvetiae republica* (Zürich, 1576, also in German and French); A Stanyan, *An Account of Switzerland* (London, 1714). *See* also W. Oechsli in vol. ii. ch viii of the *Cambridge Modern History* (1902–10). For the existing Swiss Constitution, *see* F Fleiner, *Schweizerisches Bundesstaatsrecht* (Tubingen, 1923); and the relevant chapters in J. Bryce, *Modern Democracies* (1923); also two monographs concerning the relations of Switzerland to the League of Nations, W E Rappard, *L'Entrée de la Suisse dans la Société des Nations* (Geneva, 1924) and *La Politique de la Suisse dans la Société des Nations* (Geneva, 1925)

There is no really satisfactory general ecclesiastical history of Switzerland, but much material has been collected in the *Zeitschrift fur Schweizerische Kirchengeschichte* (Stans, 1907, etc). *See* vols. i. and ii. of B Fleischlin, *Studien und Beitrage zur schweizer Kirchengeschichte* (Lucerne, 1902–03); E Egli, *Kirchengeschichte der Schweiz bis auf. Karl den Grossen* (Zurich, 1893); S Guyer, *Die christlichen Denkmaler des ersten Jahrtausends in der Schweiz* (Leipzig, 1907). For the mediaeval saints of Switzerland, *see* E A. Stuckelberg, *Die schweiz Heiligen des Mittelalters* (Zurich, 1903), and *Geschichte der Reliquien in der Schweiz* (2 vols, Zurich and Basle, 1902–08); for documentary history of some Swiss dioceses, see *Regester episcoporum constantiensium* (edit. P Ladewig and T Müller, Innsbruck, 1895, 1905, etc); for monasteries, *Die Regesten der Archive in der schweiz Eidgenossenschaft* (edit T. von Mohr, 2 vols, Coire, 1851–54); A. Nüscheler, *Die Gotteshauser der Schweiz* (3 pts. Zürich, 1864–73; continued in the *Geschichtsfreund und Argovia*, complete index as an appendix to the *Anzeiger fur schweizerische Geschichte*, 1900). *See* also A. Steinberg, *Studien zur Geschichte der Juden in der Schweiz während des Mittelalters* (Zurich, 1903) For the Reformation and later times *see* E. Bloesch, *Geschichte der schweizerisch-reformierten Kirchen* (2 vols., Berne, 1898–99); W Hadorn, *Kirchengeschichte der reformierten Schweiz* (Constance, 1906, etc); vols iii and iv of B Fleischlin, *Studien*, deal with the same period from the Roman Catholic standpoint.

For modern times, *see* C Garris and P Zorn, *Staat und Kirche in der Schweiz* (2 vols, Zurich, 1877–78); A. Büchi, *Die Katholische Kirche in der Schweiz* (Munich, 1902).

SWOLD (or Swold), **BATTLE OF,** the most famous of the sea-fights of the ancient Norsemen. It took place on Sept 9, 1,000. The place cannot now be identified. Swold was an island probably on the North German coast, near Rügen. The battle was fought between Olaf Trygvesson, king of Norway, and a coalition of his enemies—Eric Hakonson, his cousin and rival; Olaf, king of Sweden; and Sweyn Forkbeard, king of Denmark.

Olaf had been during the summer in the eastern Baltic. The allies lay in wait for him at the island of Swold on his way home The Norse king had with him seventy-one vessels, but part of them belonged to an associate, Sigwald, a chief of the Jomsburg vikings, who was an agent of his enemies, and who deserted him The allies allowed the bulk of the Norse ships to pass, and then stood out to attack Olaf.

The Norse writers, who are the only authorities, gave all the credit to their own countrymen, and according to them all the intelligence of Olaf's enemies, and most of their valour, were to be found in Eric Hakonson. They say that the Danes and Swedes rushed at the front of Olaf's line without success. Eric Hakonson attacked the flank. His vessel, the "Iron Ram," was "bearded," that is to say, strengthened across the bows by bands of iron, and he forced her between the last and last but one of Olaf's line In this way the Norse ships were carried one by one, till the "Long Serpent" alone was left. At last she too was overpowered Olaf leapt into the sea holding his shield edgeways, so that he sank at once and the weight of his hauberk dragged him down A legend of later days has it that at the last moment a sudden blaze of light surrounded the king, and when it cleared away he had disappeared King Olaf is one of that company of legendary heroic figures in whose death the people would not believe, and whose return was looked for.

See the *Heims-Kringla*, in the Saga Library, trans. by W Morris and E Magnusson (1893) and the *Saga of King Olaf Tryggwason*, trans. by J. Sephton (1895).

SWORD, a general term for a hand weapon of metal, characterized by a longish blade, and thus distinct from all missile weapons on the one hand, and on the other hand from staff weapons—the pike, bill, halberd, and the like—in which the metal head or blade occupies only a fraction of the effective length The handle of a sword provides a grip for the hand that wields it, or sometimes for two hands; it may add protection, and in most patterns does so to a greater or less extent

Early Forms.—Of the actual origin of swords we have no direct evidence. Neither does the English word nor any of the equivalent words in other languages, Aryan or otherwise, throw any light on the matter Daggers shaped from reindeer antlers occur among the earliest relics of man, and there are flint daggers of the Neolithic period, which may be supposed to have been the model for the first hand weapons made of copper. Bronze took the place of copper about 2000 B C., and the transition from bronze to iron in Europe is assigned to the period 1000 to 700 B C Whatever the further discoveries of archaeologists, we know that swords are found from the earliest times of which we have any record among all people who have acquired any skill in metal-work There are two very ancient types, which we may call the straight-edged and the leaf-shaped Assyrian monuments represent a straight and narrow sword, better fitted for thrusting than cutting Bronze swords of this form have been found in many parts of Europe, at Mycenae, side by side with leaf-shaped specimens, and more lately in Crete We have also from Mycenae some very curious and elaborately wrought blades, so broad and short that they must be called ornamental daggers rather than swords The leaf-shaped blade is common everywhere among the remains of men in the "Bronze Period" of civilization, and this was the shape used by the Greeks in historical times, and is the shape familiar to us in Greek works of art It is impossible, however, to say whether the Homeric heroes were conceived by the poet as wearing the leaf-shaped sword, as we see it, for example, on the Mausoleum sculptures, or a narrow straight-edged blade of the Minoan and Mycenaean pattern. In any case, the sword holds a quite inferior position with Greek warriors of all times Strange as it is to a modern swordsman, representations in Minoan art seem to show that not only the bronze daggers but the long swords were used with an overhand stabbing action like a modern Asiatic dagger. The handles are too short for any but a rigid grip without finger-play Before about 1500 B C. the rapier type was the prevailing one; but there is no evidence of historical connection between the Assyrian and the Minoan rapiers. It is thought that the leaf-shaped blade came to the Mediterranean countries from the north. So far as we know from works of art, it was mostly used with a downright cutting blow, regardless of the consequent exposure of the swords-

man's body; this, however, matters little when defence is left to a shield or armour, or both. Attic vases also show warriors giving point, though less often. The use of the sword as a weapon of combined offence and defence—swordsmanship as we now understand it—is quite modern. If the sword was developed from a spearhead or dagger, it would naturally have been (and it seems in fact to have been) a thrusting weapon before it was a cutting one. But when we come to historical times we find that uncivilized people use only the edge, and that the effective use of the point is a mark of advanced skill and superior civilization. The Romans paid special attention to it, and Tacitus tells us how Agricola's legionaries made short work of the clumsy and pointless arms of the Britons when battle was fairly joined. Asiatics to this day treat the sword merely as a cutting weapon, and most Asiatic swords cannot be handled in any other way.

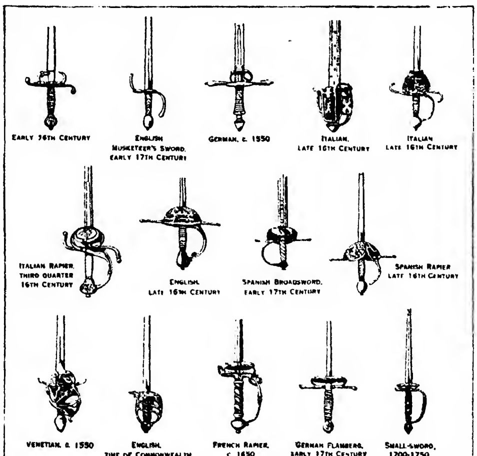
Historical Types.—The normal types of swords which we meet with in historical times, and from which all forms now in use among civilized nations are derived, may be broadly classified as straight-edged or curved. In the straight-edged type, in itself a very ancient one, either thrusting or cutting qualities may predominate, and the blade may be double-edged or single-edged. The double-edged form was prevalent in Europe down to the 17th century. The single-edged blade, or back-sword as it was called in England, is well exemplified among the Scottish weapons commonly but improperly known as claymores (the real claymore, *i.e.* great sword, *claidheamh mór,* is an earlier mediaeval form), and is now all but exclusively employed for military weapons. But these, with few exceptions, have been more or less influenced by the curved Oriental sabre. Among early double-edged swords the Roman pattern (*gladius,* the thrusting sword, contrasted with the barbarian *ensis*) stands out as a workmanlike and formidable weapon for close fight. In the middle ages the Roman tradition disappeared, and a new start was made from the clumsy barbarian arm which the Romans had despised. Gradually, the broad and all but pointless blade was lightened and tapered, and the thrust, although its real power was unknown, was more or less practised from the 12th century onwards. St. Louis anticipated Napoleon in calling on his men to use the point; and the heroes of dismounted combats in the *Morte d'Arthur* are described as "foining" at one another. In the first half of the 16th century a well-proportioned and well-mounted cut-and-thrust sword was in general use, and great artistic ingenuity was expended, for those who could afford it, on the mounting and adornment. The growth and variations of the different parts of the hilt would alone be matter enough for an archaeological study. One peculiar form, that of the Scottish basket-hilt, derived from the Venetian pattern known as *schiavone,* has persisted without material change.

Quite different from the European models is the crescent-shaped Asiatic sabre, commonly called scimitar. We are not acquainted with any distinct evidence as to the origin of this in time or place. The fame of the Damascus manufacture of sword-blades is of great antiquity, as is also that of Khurāsān. Whoever first made these blades had conceived a very definite idea—that of gaining a maximum of cutting power regardless of loss in other qualities—and executed it in a manner not to be improved upon. The action of the curved edge in delivering a blow is to present an oblique and therefore highly acute-angled section of the blade to the object struck, so that in effect the cut is given with a finer edge than could safely be put on the blade in its direct transverse section. In a well-made sabre the setting of the blade with regard to the handle ("leading forward") is likewise ordered with a view to this result. And the cutting power of a weapon so shaped and mounted is undoubtedly very great. But the use of the point is abandoned, and the capacities of defensive use (to which Orientals pay little or no attention) much diminished. These drawbacks have caused the scimitar type, after being in fashion for European light cavalry during the period of Napoleon's wars and somewhat longer, to be discarded in our own time. But, as long as Easterns adhere to their rigid grasp of a small handle and sweeping cut delivered from the shoulder, the Persian scimitar or Indian talwar will remain the natural weapon of the Eastern horseman. Indian and Persian swords are often richly adorned; but their true beauty is in the texture of the steel itself, the "damascening" or "watering" which distinguishes a superior from a common specimen.

There are special Asiatic varieties of curved blades of which the origin is more or less uncertain. Among these the most remarkable is perhaps the yataghan, a weapon pretty much coextensive with the Mohammedan world, though it is reported to be not common in Persia. It was imported from Africa, through a French imitation, as the model of the sword-bayonets which were common for about a generation in European armies. A compact and formidable hand weapon was thus turned into a clumsy and top-heavy pike. The double curve of the yataghan is substantially identical with that of the Gurkha knife (*kukri*), though the latter is so much



FROM CASTLE, "SCHOOL AND MASTERS OF FENCE" (BELL & SONS)

FIG. 2.—TYPICAL EUROPEAN SWORDS, 16TH AND 17TH CENTURIES

broader as to be more like a woodman's than a soldier's instrument. It is doubtful, however, whether there is any historical connection. Similar needs are often capable of giving rise to similar inventions without imitation or communication. There are yet other varieties which have acquired a strong individuality. Such are the swords of Japan, which are the highly perfected working out of a general Indo-Chinese type; they are powerful weapons and often beautifully made, but a European swordsman would find them ill-balanced, and the Japanese style of sword-play, being

two-handed, has little to teach us.

Other sorts of weapons, again, are so peculiar in form or historical derivation, or both, as to refuse to be referred to any of the normal divisions. The long straight gauntlet-hilted sword (*paṭā*) found both among the Mahrattas in the south of India and among the Sikhs and Rajputs in the north, is an elongated form of the broad-bladed dagger with a cross-bar handle (*kaṭār*), as shown by a transitional form, much resembling in its shape and the size of blade the mediaeval English anlace and furnished with a guard for the back of the hand When once the combination of a long blade with the gauntlet hilt was arrived at, any straight blade might be so mounted, and many appear on examination to be of European workmanship—German, Spanish or Italian. There are various other Oriental arms, notably in the Malay group, as to which it is not easy to say whether they are properly swords or not The Malay "parang latok" is a kind of elongated chopper sharpened by being bevelled off to an edge on one side, and thus capable of cutting only in one direction The anlace incidentally mentioned above seems to be merely an overgrown dagger; the name occurs only in English and Welsh; in which language first, or whence the name or thing came, is unknown

Later European Developments.—In the course of the 16th century the straight two-edged sword of all work was lengthened, narrowed, and more finely pointed, till it became the Italian and Spanish rapier, a weapon still furnished with cutting edges, but used chiefly for thrusting We cannot say how far this transition was influenced by the *estoc* or *Panzerstecher,* a late mediaeval thrusting weapon carried by horsemen rather as an auxiliary lance than as a sword. The Roman preference for the point was rediscovered under new conditions, and fencing became an art Its progress was from pedantic complication to lucidity and simplicity and the fashion of the weapon was simplified also Early in the 18th century, the use of the edge having been finally abandoned in rapier-play, the two-edged blade was supplanted by the bayonet-shaped French duelling sword, on which no improvement has since been made except in giving it a still simpler guard The name of rapier was often but wrongly given to this by English writers About the same time, or a little earlier, the primacy of the art passed from Italy to France. There is still a distinct Italian school, but the rest of the world learns from French masters It is unnecessary here to consider the history of fencing (*q v*).

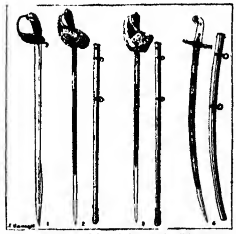
FIG 3 —ORIENTAL SWORDS

1, 2. Decorated Persian Arms. 3. Gauntlet Sword. 4. Common type of talwar (North West Provinces). 5. Yataghan type. 6. Persian talwar. 8. Kukri (Nepal). 7, 9 & 10 Mahratta, showing transition to gauntlet sword

Meanwhile a stouter and broader pattern, with sundry minor varieties, continued in use for military purposes, and gradually the single-edged form or broadsword prevailed The well-known name of Ferrara, peculiarly associated with Scottish blades, appears to have originally belonged to a Venetian maker, or family of makers, towards the end of the 16th century The Spanish blades made at Toledo had by that time acquired a renown which still continues Somewhat later Oriental examples, imported probably by way of Hungary, induced the curvature found in most recent military sabres, which, however, is such as not to interfere with the effective use of the point. An eccentric specialized variety of the sabre is the narrow and flexible "Schläger" with which German students used to fight their duels, under highly conventional rules almost identical with those of the old English "back-swording" practised within living memory, in which, however, the swords were represented by sticks.

Modern Swords.—The present military swords are descended from the straight "back-sword" and the Eastern scimitar or talwar. The difference between the curved "sabre" and straight "sword" has been preserved in some languages (*e.g.,* in German, *Degen* stands for the straight, and *Säbel* for the curved, sword), though in English the single word "sword" covers both varieties. The shape of the sword has varied considerably at different times; this is due to the fact that it is practically impossible to decide by trial whether a straight or a curved sword is the better under all circumstances The trooper can use his sword in three different ways—to cut, to guard and to point; and his success depends upon the training of his horse, his skill in horsemanship, and, above all, upon the dexterity and methods of his adversary The result is that changes have often been made in cavalry armament under the erroneous impression that the arm used has been the main cause of success The Ottoman cavalry up to the end of the 18th century was regarded as one of the best in Europe The curved European cavalry sabre so long in use may undoubtedly be traced to this cause, the superiority of the Turks being put down to their curved scimitars, though horsemanship and dash were really the dominating factors.



BY COURTESY OF (2 4) THE WILKINSON SWORD CO

FIG 4 —TYPES OF GERMAN AND BRITISH SWORDS

1. German cavalry sword (men) pattern, 1889, 35in. long 2. British cavalry sword (officers), 35⅞in. long. 3 British infantry sword (officers), 32½in. long. 4. British general officer's sword, 32½in. long

The shape of the sword to be chosen depends obviously on the purpose for which it is mainly intended. In this much-debated matter the facts appear to be as follows. A determined thrust, especially when delivered by a horseman at full speed, is difficult to parry if it gets home, it will probably kill the recipient outright or disable him for the rest of the campaign That this is the case is borne out by the very large proportion of killed as compared with wounded in the British cavalry when engaged with that of the French in the Peninsular War, the French making much use of the point, and their heavy cavalry being armed with a long straight sword. On the other hand, to deliver a bold thrust, while disregarding the uplifted sword of the adversary, and leaving one's own body and head open to an impending blow, demands complete confidence that the thrust will get home before the blow can descend Such confidence can only be the fruit of long training, especially as it is the natural tendency of all men to cut when excited; therefore, in view of the excitement of the *mêlée,* it is considered by many unwise to adopt a sword with which a powerful cut cannot be delivered as well as an effective thrust The swords adopted by most nations in recent times have represented a compromise. They have blades which are nearly straight, but of sufficient weight towards their points to enable an efficient cut to be delivered with them France, however, in 1898 decided on a long straight sword designed wholly for thrusting practically identical with that which was in use about a century ago. The following year Great Britain introduced a slightly curved weapon, but in 1908 a new sword was adopted which has a long straight blade and is intended to be used chiefly for thrusting

Dobrée, "Japanese Sword Blades" in the *Archaeological Journal*, vol. lxii., pp. 1–18 and pp. 218–255 (1905); and for the export of European blades to India *see* Lord Dillon, *ibid.*, p. 67 and pp. 69–72.

SWORDFISH (*Xiphias gladius*), a large fish, widely distributed in warm seas, purplish in colour, and with the snout prolonged to form a long, flat "sword." As in the mackerels, to which it is related, the caudal peduncle is slender and the caudal fin is widely forked. It reaches a weight of over 600 lb. It swims swiftly at the surface and feeds on other fishes, especially mackerel, and is said to dash into a school, killing a number with slashes of its sword. The flesh is red and oily and is valued as food; fisheries exist in the Mediterranean and off the Atlantic coast of America, the usual method being harpooning.

Related to the swordfish are the spear-fishes (*Tetrapturus*) and sail-fishes (*Histiophorus*): in these the rostrum is not flattened, but is spear-like, rounded in transverse section. Each genus has two or three species, all large fishes of warm seas. *Histiophorus nigricans* of the Atlantic is a beautiful fish, silvery and blue-backed, with the very large sail-like dorsal fin deep blue, with numerous round black spots. The members of this group are said to attack whales in company with killers (*Orca*) and it is certain that they frequently attack ships, presumably mistaking them for whales. The sword or spear may be driven into a wooden ship with such force that the fish, in order to get free, has to break it off short. In the Natural History Museum in London is a piece of timber, less than a foot square, containing the broken ends of three spears.

SWOYERSVILLE, an anthracite-mining borough of Luzerne county, Pennsylvania, U.S.A., 3 m. N. of the public square of Wilkes-Barre, with which it is connected by trolley and motor-bus lines. Pop. (1920) 6,876 (32% foreign-born white); 1928 local estimate 9,000.

SWYNFORD, CATHERINE (*c.* 1350–1403), wife of John of Gaunt, duke of Lancaster, was a daughter of Sir Payne Roelt, a knight who came to England from Hainault in the train of Edward III.'s queen, Philippa. About 1367 she married Sir Hugh Swynford (1340–1372), a Lincolnshire man, by whom she had a son, Thomas (*c.* 1368–1433), who was a friend and companion of Henry IV. Soon after her husband's death in 1372 Catherine became the mistress of John of Gaunt, and in 1396 she was married to him at Lincoln. She died at Lincoln on May 10, 1403. By John of Gaunt Catherine had four children, all of whom were born before their marriage. They were declared legitimate in 1397 and took the name of Beaufort from one of their father's castles in Anjou. (*See* BEAUFORT.)

SYAGRIUS (d. 487), the last of the independent Roman administrators of Gaul, was the son of Aegidius, who had seized Gaul while Ricimer was master of Italy. Defeated in 486 by Clovis, king of the Salian Franks, at the battle of Soissons, Syagrius fled, leaving his land at the mercy of the Franks. He sought refuge with Alaric II., king of the Visigoths, at Toulouse, but Alaric imprisoned him instead of granting him refuge, and delivered him up to Clovis. He was executed in 487, secretly and by the sword, according to Gregory of Tours.

SYBARIS, a city of Magna Graecia, on the Gulf of Tarentum, between the rivers Crathis (Crati) and Sybaris (Coscile), which now meet 3 m. from the sea, but in ancient times had independent mouths, was the oldest Greek colony in this region. It was an Achaean colony founded by Isus of Helice (about 720 B.C.), but had among its settlers many Troezenians, who were ultimately expelled. Placed in a very fertile, though now most unhealthy, region, and following a liberal policy in the admission of citizens from all quarters, the city became great and opulent, with a vast subject territory and daughter colonies even on the Tyrrhenian sea (Posidonia, Laus, Scidrus). For magnificence and luxury the Sybarites were proverbial throughout Greece, and in the 6th century no Hellenic city could compare with its wealth and splendour. At length contests between the democrats and oligarchs in which many of the latter were expelled and took refuge at Crotona, led to a war with that city, and the Crotoniats, with very inferior forces, were victorious. They razed Sybaris to the ground and turned the waters of the Crathis over its ruins (510 B.C.). Explorations have so far failed to lead to a precise knowledge of the site. The only discoveries have been (1) that of an extensive necropolis, some 8 m. to the west of the confluence of the two rivers, of the end of the first Iron age, known as that of Torre Mordillo, the contents of which are now preserved at Potenza; (2) that of a necropolis of about 400 B.C.—the period of the greatest prosperity of Thurii (*q.v.*)—consisting of tombs covered by tumuli, in some of which were found fine gold plates with mystic inscriptions in Greek characters.

SYBEL, HEINRICH VON (1817–1895), German historian, was born on Dec. 2, 1817, at Düsseldorf. Sybel was educated at the gymnasium of his native town, and then at the University of Berlin, where he came under the influence of Savigny and of Ranke, whose most distinguished pupil he was to become. In 1841 he settled at Bonn as *Privatdozent* in history. He was already known by his *Geschichte des ersten Kreuzzuges* (Düsseldorf, 1841; new ed., Leipzig, 1881; Eng. trans. by Lady Duff-Gordon, 1861). This was followed by a study on the growth of German kingship (*Die Entstehung des deutschen Königtums*, Frankfurt, 1844, and again 1881), after which he was appointed professor. In the same year (1844) Sybel came forward as an opponent of the Ultramontane party. In 1846 he was appointed professor at Marburg, while a seat in the Hessian Landtag gave him his first experience of political affairs. In 1848 he was present at Frankfurt, but did not sit in the National Assembly. His opposition to the revolutionary party made him unpopular with the mob, who broke his windows, as his liberalism made him suspected at court. He sat in the Erfurt parliament of 1850, and was attached to the Gotha party, which hoped for the regeneration of Germany through the ascendancy of Prussia. During the years of reaction that followed all political activity was impossible, but he was fully occupied with his great work, *Geschichte der Revolutionszeit 1789–1800*, for which he had made prolonged studies in the archives at Paris and elsewhere. The later editions of the

earlier volumes are much enlarged and altered, and a new edition was published at Stuttgart in 1882. The first three volumes have been translated into English by W. C. Perry (1867–69). In this work he for the first time showed the connection between the internal and external history of France; he was also the first, by a systematic study of the records, to check and correct the traditional accounts of numerous episodes connected with the internal history

In 1856 Sybel accepted the post of professor at Munich. Here he founded the *Historische Zeitschrift*, the original and model of the numerous technical historical publications which now exist. In the political excitement which followed the war of 1859 he found that he could not hope for the unreserved support of the king, and therefore in 1861 he accepted a professorship at Bonn, which he held till 1875. He was at once elected a member of the Prussian Lower House, and during the next three years was an active member, opposing the policy of Bismarck, not only on financial but also on the Polish and Danish affairs. In 1864 he did not stand for re-election. In 1866 he was one of the first to point out the way to a reconciliation between Bismarck and his former opponents. He had a seat in the Constituent Assembly of 1867, and while he joined the National Liberals he distinguished himself by his opposition to the introduction of universal suffrage, the effects of which he, as did many other Liberals, much distrusted. In 1874 he again accepted a seat in the Prussian parliament, supporting the Government against the Clericals, and after 1878 against the Socialists. In 1880 he retired

In 1875 he had been appointed by Bismarck director of the Prussian archives. Under his superintendence was begun the great series of publications, besides that of the correspondence of Frederick the Great, in the editing of which he himself took part. His last years were occupied on his great work, *Die Begründung des deutschen Reiches durch Wilhelm I.* (Munich, 7 vols, 1889–94; Eng. trans., 1890–91), for which he was allowed to use the Prussian state papers, and was therefore enabled to write a history of his own time with full access to the most secret sources of information As a history of Prussian policy from 1860 to 1866 it is of incomparable value After the fall of Bismarck permission to use the secret papers was withdrawn, and therefore vols. vi. and vii, which deal with the years 1866 to 1870, are of less importance. He died at Marburg on Aug. 1, 1895.

SYCOPHANT, in ancient Greece the counterpart of the Roman delator (*q.v*), a public informer (Gr. συκοφάντης). According to ancient authorities, the word (derived by them from σῦκον, "fig" and φαίνειν, "to show") meant one who informed against another for exporting figs (which was forbidden by law). This derivation is doubtful and the question is still contested. Any Athenian citizen was at liberty to accuse another of a public offence. Allusions to the sycophants are frequent in Aristophanes and the Attic orators. The word is now generally used in the sense of a cringing flatterer of the great.

See L. Whibley, *Companion to Greek Studies* (1916).

SYDENHAM, CHARLES EDWARD POULETT-THOMSON, 1st Baron (1799–1841), British statesman, was born on the 13th of September 1799, being the son of John Buncombe-Poulett-Thomson, a London merchant. After some years spent in his father's business in Russia and in London he was returned to the House of Commons for Dover in 1826. In 1830 he joined Lord Grey's ministry as vice-president of the board of trade and treasurer of the navy. A free-trader and an expert in financial matters he was elected M P. for Manchester in 1832, a seat which he occupied for many years He was continuously occupied with negotiations affecting international commerce until 1839, when he accepted the governor-generalship of Canada, where it fell to his lot to establish the union of Upper and Lower Canada. His services in establishing the Canadian constitution were recognized in 1840 by a K.C.B. and a peerage He took the title of Baron Sydenham of Sydenham in Kent and Toronto in Canada. He died unmarried on the 4th of September 1841, when his peerage became extinct

His *Memoirs* were published by his brother, G. J. Poulett Scrope, in 1843.

SYDENHAM, GEORGE SYDENHAM CLARKE, 1st Baron (1848–), British soldier and administrator, a leading authority on fortification, was born in Lincolnshire on July 4, 1848. Educated at Haileybury and Wimbledon, and afterwards at the Royal Military Academy, in 1868 he entered the Royal Engineers. Having served in various expeditions abroad, he returned to England in 1885, and was employed at the War Office until 1892 From 1894 to 1901 he was superintendent of the royal carriage factory at Woolwich. Sydenham earned a great reputation as an authority on military questions, particularly fortification. On his retirement from Woolwich he was made a member of the committee on War Office reorganization. In 1901 he was appointed governor of Victoria (Australia), and on his retirement in 1904 he became secretary to the Committee of Imperial Defence. From 1907 to 1913 he was governor of Bombay. He had been created G C.M.G. in 1905, and in 1913 was raised to the peerage. In addition to his classic work on *Fortification* (1890; 2nd ed. 1907), his publications include *The Navy and the Nation* (1897), *Imperial Defence* (1898) and *Studies of an Imperialist* (1928).

SYDENHAM, THOMAS (1624–1689), English physician, was born on Sept. 10, 1624, at Wynford Eagle, Dorset, the son of a country gentleman He received his M B from Oxford in 1648, and about the same time became a fellow of All Souls After further study and a period of service in the Puritan army, Sydenham continued his researches at Montpellier. In 1663 he passed the examinations of the College of Physicians and was thereby able to practise in London. In 1676 he became M.D. of Cambridge. He died in London on Dec. 29, 1689.

Sydenham's fame among his contemporaries rested on his successful cooling treatment of smallpox, on his laudanum (the first form of a tincture of opium), and on his use of Peruvian bark in quartan agues But his more important contributions to medicine soon became recognized, and he himself regarded as the English Hippocrates He revived the Hippocratic idea of Epidemic Constitutions, and made an elaborate study of the variations in epidemics of different diseases according to different seasons, years and ages. Further, rejecting the traditional dogmas of medicine and insisting that observation should have precedence over theory, Sydenham diligently studied the natural histories of diseases and contended that most forms of ill-health could be ranked in certain definite species His title of the founder of modern clinical medicine is warranted by his clear accounts of the diseases of his day, especially of malaria, plague, smallpox, hysteria and gout. Sydenham is also credited with the first diagnosis of scarletina and with the modern definition of cholera Acute diseases, such as fevers and inflammations, he regarded as a wholesome effort of the organism to resist injurious influences operating from without, but chronic diseases he held to be due to a depraved state of the humours arising from errors of diet and methods of life.

Sydenham's chief works are: *Methodus curandi febres* (1666), which appeared in a 3rd edition under the better-known title of *Observationes medicae* (1676); two *Epistolae responsoriae* (1680), one "on Epidemics" and one "on the Lues venerea"; *Dissertatio epistolaris* (1682), an account of hysteria, and *Tractatus de podagra et hydrope* (1683), his famous description of gout. His last completed work, *Processus integri*, is an outline sketch of pathology and practice; twenty copies of it were printed in 1692, and, being a compendium, it has been more often republished both in England and in other countries than any other of his writings separately. A fragment on pulmonary consumption was found among his papers His collected writings occupy about 600 pages 8vo, in the Latin, though whether that or English was the language in which they were originally written is disputed. The collected works appeared at Amsterdam (1683), and lastly in London (1846, edit. W A. Greenhill). An Eng trans, together with a biography, was produced by R G. Latham (2 vols., London, 1848)

See also F Picard, *Sydenham, sa vie, ses oeuvres* (1889); J. F Payne, *T. Sydenham* (1900); and M. Greenwood, "Sydenham as an Epidemiologist," in the *Proceedings* of the Royal Soc. of Medicine (vol. xii., 1919).

SYDENHAM, a large residential district in the south of London, England, partly within the metropolitan borough of Lewisham (*q v.*). The Crystal Palace (*q v*) is in this district.

SYDNEY, a city situated in the Sydney Basin (County Cum-

berland) is the capital of New South Wales, Australia, and lies (lat. 33° 52′ S., 151° 12′ E.) mainly on the south shore of Port Jackson somewhat south of the central east of the State. The oval-shaped area which extends from about Broken Bay (Hawkesbury River estuary) on the north to a little beyond Port Hacking on the south, and from the coast east of Sydney *c.* 40 miles inland (near Glenbrook) forms the lower part of a geological and tectonic basin which is disposed fairly symmetrically about the line Botany Bay–Penrith.

The Sydney Basin is enclosed on three sides by flattish highlands which are, moreover, deeply dissected and seamed with gorges by streams which now, for the most part, form part of the Hawkesbury system but which formerly had different (westward and north-westward) courses and were dislocated by the late (Tertiary?) uplift which raised the plateaux. On the seaward side, also, recent earth-movements have resulted in the drowning of river valleys and created spacious inlets—Port Hacking, Botany Bay, Port Jackson, Broken Bay—but here also the basin-edge structure is apparent in the upstanding cliffs which form an outer rampart along the coast and give rise, at the entrance of Port Jackson, to the famous Sydney Heads, great sandstone cliffs which admit between them a deep (80 ft. low-water) sea passage of a minimum breadth of ¾ mile.

The Sydney Basin is one of the largest coastal lowlands of the State, but its lack of easy land communications makes the presence and growth of Sydney seem somewhat surprising. The reasons are partly physical but more historical: the superiority of the deep and sheltered harbour, defensible yet easily accessible from the sea, gave it an advantage over the shallower and more open Botany Bay and the semi-silted Port Hacking, and when Governor Phillip, in 1788, removed the early settlement from Botany Bay, he chose the small deep-water cove at the head of which now stands Circular Quay, but where was then a fresh-running stream (Tank Stream) now obliterated.

Port Jackson, sheltered from the southerly gales, covers an area of 22 sq.miles and has a highly embayed coastline—a succession of romantic low bluffs and coves, still often densely wooded, giving a total shore-line of nearly 190 miles. It opens a way into the heart of the lowlands and upon its southern and lower shores (elevation 100 ft.) the original settlement grew. For some time it was, from the point of view of its founders, not only "the State," but "all Australia," and from it emanated, and upon it centred, much of the energy and initiative which built up the growing colony. Hence its triumph over physical obstacles, for the roads and the railways have had to cross the highlands at one of their most difficult sections, and, outside the basin, and apart from a few special areas—*e.g.*, mining centres, and also the tourist resorts (Katoomba, etc.) attracted by elevation and scenery—the barren and rugged highlands at a distance of 50 miles are still almost unoccupied. The city expanded rapidly (pop. 1861: 97,061; 1901: 487,932; 1921: 906,103) until (1926/7) the total Metropolitan Area counted 1,070,510 inhabitants (1927/8; 1,101,190) or *c.* 45·5% of the total population of the State. The metropolitan area includes the city proper (3,244 ac.; pop. 1926/7: 107,880) surrounded by an extensive group of suburbs (40 municipalities, together with the Ku-ring-gai Shire, and the islands, giving the total, 1,070,510 in 181 sq. miles.

The Metropolitan Area, however, as defined in 1919, now includes 7 additional municipalities and 3 shires giving a total pop. (1926/7) of 1,201,750 in 685 sq. miles. Thus what is virtually the Sydney Basin contains 50·7% of the total population of the State and has a density of 1,700·3 per sq. mile. (Sydney and suburbs alone: 5,742·5; other municipalities, etc., alone: 248·6 per sq. mile.) As the city grows, industrial and commercial occupation advances and the residential areas are pushed farther out. Thus the higher and less accessible northern shores of the harbour have developed mainly as residential areas (*e.g.*, Ryde, pop. 21,630). Industries are expanding along the south—Redfern (24,100), Paddington (26,750), Balmain (32,660)—and also westwards—Granville (16,800), Parramatta (16,400), Lidcombe (13,540)—so that residential areas are now developing further afield—along the south-east coast (Randwick: 66,870) and in the Botany Bay (*q.v.*) area—Bexley (18,100), Kogarah (25,000), Hurstville (18,390), Canterbury (60,450). The climate is in general healthy and invigorating, cool and bracing with westerly winds in winter (May to September inclusive), hot and sometimes unpleasantly humid in summer. The prevailing winds from October–April (inclusive) are from the north-east. Mean temps. range from 70·1° F in summer to 56·2° F in winter, with extremes 108·5° F and 35·9° F. Sydney is a city of sunshine: 2,168 hr. per annum. Rainfall is distributed throughout the year but shows an autumn and winter maximum (Feb.–July) and averages 47½ in. Sydney, besides its splendid site, has had the advantage of fine and easily procured building stone, the sandstones of Pyrmont and other local quarries. The old town had winding, narrow and relatively enclosed streets. In spite of much recent rebuilding—notably along the water-fronts—some of these persist and give the city an old-world flavour. The public buildings are, in many cases, notably fine, the two Cathedrals (Anglican and Roman Catholic), the University, Post Office, several of the Government offices, besides some of the public galleries, etc., being worthy of note. The main streets also offer excellent specimens of modern lay-out and substantial architecture, while many other buildings (Government House, etc.) have historical interest. The city is unusually well endowed with parks, recreation grounds, and pleasure resorts generally. The 647 ac. of parks, etc., within the city boundaries include Moore Park, the fine Botanic Gardens, the Domain, Hyde Park which commands many splendid views; in addition the Sydney Cricket Ground, the Royal Agricultural Society's Ground where is held annually the most famous agricultural show in the State. There are 6,000 ac. of similar reserves in the municipalities, and two national reserves: National Park, 16 miles south of Sydney (33,800 ac.) around Port Hacking, and the Kuringgai Chase (35,300 ac.) 15 miles north on Broken Bay—both with magnificent scenery—besides reserves at Parramatta and Botany Bay, making a total (1926) of 240,200 ac. reserves besides 440,000 ac. commons within the (greater) metropolitan area.

The harbour of Sydney, with its coves, creeks and bays, is a favourite pleasure resort, as are also such beaches as Manly for surf-bathing, etc. Sydney has an excellent and assured water-supply derived chiefly from the Nepean, Cataract and Cordeaux Rivers (347 sq.miles catchment), the reservoirs containing (1927) 80,000 million gal. Trams (375 m. of track of which 288 miles are electric, the remainder steam) and electric and steam railways serve the city and suburbs, ferries ply in the harbour, and the great Sydney Bridge now being constructed will span the harbour from Dawes Point (south) to Milson Point (north), have a total length of 3,770 ft.—(main arches' span, 1,675 ft.; headway for vessels passing beneath: 170 ft.)—and will carry a roadway (57 ft.), 2 footways, and 4 lines of railway. The bridge when completed (*c.* 1931) will probably be the largest bridge in existence. The city is, in respect of its social, educational and artistic life a leading city of the southern hemisphere.

There are 5,170 factories employing 135,500 hands in the Sydney Basin area (Cumberland County) and of these 4,880 factories and 128,500 hands are in the metropolitan area. Clothing, metal, machinery (including railway engineering) industries are the most important, food and drink preparation coming next. (For industrial areas and suburbs: *v. sup.*) Sydney is also the chief commercial, banking, warehousing and shipping centre of the State. Upon it are centralized the lines, not only from its own basin, but from a very large part of the State. Wheat, meat, butter, fruit and many other primary products find their way to the city, from inland or by coasting steamers, for consumption or for export, but most important and most characteristic is wool. Sydney is by far the largest wool-selling centre in Australia and its sales, which begin in Sept. and last for 8–9 months, are world-famous. Sales range from 107·5 mill.–374 mill. lb. (1913/4–1926/7), valued at £5·6–£26·4 mill. annually. Port Jackson (*v. sup.*) offers unrivalled opportunities for harbour development.

The Sydney Harbour Trust (constituted in the year 1901) has pursued a vigorous policy of development and improvement and largely transformed the earlier unsatisfactory state of much

of the water-front. The principal wharves lie 4–5 miles from the Heads and close to the business centre of the city. The Trust controls *c* 63,000 ft. of wharfage which is leased to shipping companies, etc. Woolloomooloo Bay (6,000 ft. wharfage) is the principal overseas harbour; Circular Quay (3,600 ft) is used both for ferry and overseas traffic; Glebe Island (4,800 ft.) is the wheat-exporting harbour with modern appliances including an elevator of 6,500,000 bu. capacity, and there are also wool, timber, and other special cargo wharves, warehouses, etc. All these are on the southern shores and do not include ferry wharves, private jetties, etc. The Islands (9) in Port Jackson are either pleasure resorts or used for special (naval, fire-station, etc.) purposes. On Cockatoo Is. and at Woolwich are large graving docks. Some 7,500–8,500 vessels (7,500,000–9,130,000 tons) have entered Sydney Harbour in recent years, of which *c.* 2,400 (7,200,000 tons) are engaged in overseas, the remainder in inter-State (coasting), trade. In 1925/6, 1,765,000 tons of cargo were shipped (1,100,000 tons, £52,193,000, overseas) and 2,779,000 tons were discharged (1,936,000 tons, £62,180,000) from overseas. The total overseas trade is valued at £114,374,000, constituting Sydney easily the first port in Australia and one of the foremost in the British Empire.

See Griffith Taylor, "The Warped Littoral Around Sydney" in *Proc. Royal Soc. N.S W.*, vol lvii, 1923, and also in *Commonwealth Year Book*, No. 20, 1927, etc ; K Ussher, *The Cities of Australia* (1928); *Official Year Book of N.S.W.* (1926–27).

SYDNEY, the chief city of Cape Breton county, Nova Scotia, on a good harbour, the eastern terminus of the Canadian National railway. Pop. (1921) 22,545. Formerly a quiet country town, it became between 1891 and 1901 the chief shipping port of the Dominion Coal company, and the site of the large works of the Dominion Iron and Steel company. On the opposite side of the harbour are the flourishing towns of North Sydney and of Sydney Mines It is the starting point for the line of steamers to the Bras d'Or lakes, and a favourite summer resort.

SYED AHMAD KHAN, SIR (1817–1898): *see* SAYYID AHMAD KHAN, SIR.

SYENITE, in petrology, the group name for a class of plutonic rocks composed essentially of an alkali felspar and a ferromagnesian mineral. A special group of alkali-syenites is characterized by the presence of a felspathoid mineral (nepheline, leucite, analcime or sodalite).

The name was first used by Pliny for the rock occurring at Syene (Assuan) on the Nile in Upper Egypt This rock, so extensively worked in ancient times for monumental structures, is a hornblende-granite with abundant quartz; Werner subsequently adopted the name for the class of rocks defined above, of which the type example is the hornblende-syenite of the Plauen'scher Grund, near Dresden. As essential constituents there occur soda-orthoclase and green hornblende with subordinate amounts of oligoclase felspar. The texture of syenites is like that of the granites, hypidiomorphic-granular. Mineralogically these rocks differ from granites only by the absence or scarcity of quartz The alkali-felspars include orthoclase, perthite or albite, more rarely microcline, while the ferromagnesian mineral may be biotite, hornblende or pyroxene. In the alkali-syenites, the amphiboles or pyroxenes are frequently soda-bearing varieties. The more normal syenites are divisible into augite-, hornblende-, and biotite-syenites according to their prevalent dark-coloured mineral, but syenites are also divisible, as in the case of granites, into potash and soda syenites, according to the type of alkali-felspar. The accessory constituents include sphene, apatite, zircon, magnetite and pyrites. Quartz, except in the special group of alkali-syenites, is rarely absent, but never abundant. A special suite of accessory minerals, cancrinite, eudialyte eucolite, katapleiite, melanite, corundum, etc., is found in this latter class. Syenites are by no means common, and are not of equal importance with granites and diorites from a geological standpoint.

Among the potash syenites, are classed the original hornblende-syenite (Plauen), and the well known hornblende-syenite of Biella, Piedmont, of which analyses are given below.

The rocks known as nordmarkite, akerite, larvikite and pulaskite are classed among the soda syenites. Of these the first two are quartz-bearing and were originally described from the Oslo region (Norway). Nordmarkite is built up of pink microperthite and subordinate aegirine and arfvedsonite together with some quartz. Akerite is a quartz bearing augite-syenite with considerable plagioclase The larvikites are augite-syenites with large cryptoperthitic (anorthoclase) felspars possessing a remarkable schiller structure. They are coarse-grained rocks, originally described from Larvik (Norway), and their great freshness and iridescent appearance when polished make them favourite ornamental stone for façades and pillars. The subordinate constituents are titaniferous augite, olivine, and barkevikitic hornblende. The pulaskite syenites, first described from the Fourche mountains, Ark., consist of soda-orthoclase, alkali-hornblende together with some biotite. The occasional presence of nepheline indicates their close relation to the nepheline-syenites (*q.v.*). Rocks transitional between syenites and diorites are known as monzonites (*q.v.*).

The following analyses show the chemical composition of a few of the principal types of syenite. They are characterized by a moderate amount of silica, relatively high alkalis and alumina, while lime and magnesia are more variable, but never in great amount

	SiO_2	Al_2O_3	Fe_2O_3	FeO	MgO	CaO	Na_2O	K_2O
1	60 52	16 65	2 97	2 15	2 32	4·73	4 43	4·39
2	59·37	17 92	6 77	2 02	1·83	4 16	1 24	6 68
3	59·88	17 87	2 67	1 50	1 04	2 01	7 96	5 69
4	58 88	20 30	3 63	2 58	0 79	3 03	5 73	4 50
5	58 97	16 33	2·72	4 14	2·72	4 29	4 10	4 54

1. Hornblende-syenite, Plauen'scher Grund, Dresden
2. Hornblende-syenite, Biella, Piedmont
3. Nordmarkite, Oslo, Norway
4. Larvikite, Larvig, Norway
5. Syenite (mean of 12 analyses).

(C. E. T.)

SYKES, SIR MARK, 6TH BARONET (1879–1919), English traveller and politician, was born on March 16, 1879, in London, the only son of Sir Tatton Sykes, 5th baronet He was educated at Beaumont college, Windsor, at Monaco, at Brussels and at Jesus college, Cambridge. He served with the Yorkshire Militia in the South African War (1902). On his return he travelled for some time in Syria, Mesopotamia and southern Kurdistan, and. after a short period (1904–05) as secretary to George Wyndham in Ireland, was appointed honorary attaché to the British embassy in Constantinople.

At the outbreak of the World War he raised a battalion of the Yorkshire Regiment, but did not accompany it to France He was sent by the Government on important special missions to Bulgaria, Serbia, Russia, Mesopotamia and Syria. His special knowledge and qualifications led, in 1915, to his participation in the Anglo-French conversations in London on the Syrian question He was an enthusiastic advocate of Arab independence The settlement arrived at is known as the "Sykes-Picot Agreement" Sykes then became attached to the Foreign Office and was on several occasions sent on missions to Egypt. He was on friendly terms with the Arabs and designed the flag under which they marched to Damascus. In 1918, hoping to reconcile the aims of the French and the Arabs, he established himself at Aleppo, and his diplomacy in a difficult position rendered valuable service to the Government. His efforts, however, told on his health and he died in Paris of influenza on Feb. 16, 1919

His publications include: *Through Five Turkish Provinces* (1900); *Dar-ul-Islam* (1904); *Five Mansions of the House of Othman* (1909); *The Caliph's Last Heritage* (1915)

See Shane Leslie, *Mark Sykes, his Life and Letters* (1923); for the terms of the Sykes-Picot Agreement, *see* Temperley, *History of the Peace Conference at Paris* (vol. vi., 1924).

SYKES, SIR PERCY (MOLESWORTH) (1867–), British soldier, was born on Feb. 28, 1867, and educated at Rugby and Sandhurst. In 1888 he obtained a commission in the 16th Lancers, afterwards being transferred to the 2nd Dragoon Guards. In 1893 he began his travels in Baluchistan and Persia, in the

course of which he founded the consulates for Kerman and Persian Baluchistan (1894) and in Seistan (1899). During the South African War, he was a member of the Intelligence department, and also commanded with distinction the Montgomery Imperial Yeomanry. After holding appointments as consul-general for Khurasan (1905–13), and for Chinese Turkistan (1915) he was created K.C.I.E. in 1915. In 1916 he was appointed with the rank of brigadier-general and the title of inspector-general, to organize a force of Persian troops to restore order in Southern Persia. This step was taken in consultation with the Persian Government. The force was to be 11,000 strong, and the Cossack brigade was to be raised to a similar strength. He landed at Bandar Abbas in March 1916. For an account of the campaign *see* PERSIA, CAMPAIGNS IN. Sykes held the post of G.O.C. in Southern Persia until the end of 1918. In 1919 he received the C.B., and he retired in Sept. 1920.

He has published accounts of his travels in *Ten Thousand Miles in Persia* (1902); *The Glory of the Shia World* (1910); *Through Deserts and Oases of Central Asia* (with Ella Sykes, 1920). He has also written a *History of Persia* (1915), a biography of Sir Mortimer Durant (1926) and articles for this *Encyclopædia.*

SYLHET, a town and district of British India, in the Surma valley division of Assam. The town is on the right bank of the river Surma, on rising ground, embowered in groves, and has a station on the Assam-Bengal railway. With a population (1921) of 16,912, it is, next to Shillong, the largest town in Assam. The chief institutions are the Murarichand college, Sanskrit college, Madrasa and leper asylum.

The DISTRICT OF SYLHET has an area of 5,680 sq. miles. It consists of the lower valley of the Surma or Barak river, and for the most part is a uniform level, broken only by scattered clusters of sandy hillocks called *tilas,* and intersected by a network of rivers and drainage channels. It is a broad and densely-cultivated plain. The rainfall is heavy, reaching an annual average of 159 in., of which over 100 in. fall between June and October.

In 1921 the population was 2,541,341. The normal cultivated area is 2,400,000 ac., giving an average of nearly an acre a head, but much of the district is low lying and subject to floods. Tea cultivation is a flourishing industry in the southern hills. The tea gardens had a population in 1921 of 169,000, with 90,000 ac. under tea and an output of 29,000,000 pounds. Lime is extensively quarried; under the Mogul Government Sylhet lime was a monopoly of the nawabs of Bengal. Other industries are boat-building and the manufacture of fine reed mats, buttons from fresh-water shells, ironwork inlaid with brass, and perfume: the perfume is exported to Turkey, Arabia and China.

SYLLABUS, literally something taken together, a collection (Late Lat. *syllabus*), hence a compendium, table or abstract giving the heads, outline or scheme of a course of lectures, teaching, etc. The word in the sense of a list or catalogue is used of a collection of eighty condemned propositions, addressed by order of Pius IX. to all the Catholic episcopate, under the date of the 8th of December 1864. The official title is: "A collection (*syllabus*) containing the principal errors of our times as noted in the Allocutions, Encyclicals and other Apostolic Letters of our Holy Father Pope Pius IX." Discussion of disputed doctrines began in 1849. All aspects were thoroughly debated by clerical and lay theologians gathered in a commission in 1861. The result of it was the Syllabus, in eighty propositions, arranged under the distinct heads; the propositions are not accompanied by any theological censure, but simply by a reference to the Allocution, Encyclical or Letter from which each had been more or less textually extracted. This was addressed to the episcopate together with a letter from Cardinal Antonelli, and dated the 8th of December 1864, the same date as the Encyclical *Quanta cura,* from which, however, it remains quite distinct. Its publication aroused the most violent polemics; what was then called the Ultramontane party was loud in its praise; while the liberals treated it as a declaration of war made by the Church on modern society and civilization. Napoleon III.'s government forbade its publication, and suspended the newspaper *l'Univers* for having published it. Controversies were equally numerous as to the theological value of the Syllabus. Most Catholics saw in it as many infallible definitions as condemned propositions; others observed that the pope had neither personally signed nor promulgated the collection, but had intentionally separated it from the Encyclical by sending it merely under cover of a letter from his secretary of state; they said that it was hastily, and sometimes unfortunately drawn up (*cf.* prop. 61); they saw in it an act of the pontifical authority, but without any of the marks required in the case of dogmatic definitions; they concluded, therefore, that each proposition was to be appreciated separately, and in consequence that each was open to theological comment. That such is the true view is proved by the fact that Rome never censured the theologians who, like Newman, took up this position. (The condemned propositions are given in convenient form in Latin and English in Schaff, *Creeds of Christendom,* vol. ii., "Greek and Latin Creeds," pp. 213 *sqq.*)

BIBLIOGRAPHY.—The documents from which the propositions of the Syllabus were borrowed have been collected together in the *Recueil des allocutions consistoriales,* etc., *citées dans l'encyclique et le syllabus* (Paris, 1865). For the history of the Syllabus: P. Hourat, *Le Syllabus, étude documentaire* (Paris, 1904); and P. Rinaldi, *Il Valore del sillabo* (Rome, 1888). For its theological value: Newman, *A Letter Addressed to his Grace the Duke of Norfolk* (London, 1875); P. Viollet, *L'Infallibilité du pape et le syllabus* (Paris, 1904); L. Choupin, *Valeur des décisions doctrinales et disciplinaires du Saint Siège* (Paris, 1907). *See* also Mgr. Dupanloup, *La Convention du 15 septembre et l'encyclique du 8 décembre* (Paris, 1865); and for the opposite view, *see* Trarieux, *Le Syllabus et la déclaration des droits de l'homme* (Paris, 1902).

SYLLOGISM, in logic, denotes a mediate argument, that is an argument in which an inference is drawn about the relation between two terms from two premises which state the relation of each of the two terms to the same third term. For instance, "The morning star is Venus; the evening star is Venus; therefore the evening star is the morning star" (or *vice versa*). It is usual to say that syllogism is not only mediate but also deductive reasoning, that is to say that it requires the application of a general premiss to relevant cases. For example, "All planets move in elliptical orbits; Venus is a planet; therefore Venus moves in an elliptical orbit." This argument is mediate, like the previous example; but it is also deductive (or involves the application of a general premiss, or a premiss concerning a whole class of objects) whereas the previous example was not deductive. Now, it is true that syllogisms are mostly deductive as well as mediate, but there is no sufficient reason for restricting the term to deductive cases only. Moreover, just as an argument may be mediate without being also deductive, so an inference may be deductive without being mediate. For instance, "All watches have a hair-spring; therefore my watch has one." It is also customary to restrict the term syllogism to arguments the propositions of which involve only relations of substance and attribute, as in the above examples. But for this also there is no good reason. The arguments (1) "$x=y$; $y=z$; therefore $x=z$." and (2) "M is north of P; S is west of M; therefore S is north-west of P," are also syllogisms. For, after all, "syllogism" means "thinking together" or, as one might say, "putting two and two together." It is true, however, that syllogisms involving other relationships than those of identity or of substance and attribute require special care, much more than the others. *See* LOGIC.

SYLT, the largest German island in the North Sea, being about 38 sq.m. in area and nearly 23 m. long. It is, however, very narrow, being generally about half a mile in width, except in the middle, where it sends out a peninsula to the east 7 m. across. It lies from 7 to 12 m. from the Schleswig coast. The chief places are Keitum, Tinnum, Morsum, Rantum and Westerland. The latter is a favourite pleasure resort. During the Danish War of 1864 the island was in the hands of the Danes but was occupied by the Prussians later in that year. (*See* FRISIAN ISLANDS.)

SYLVANITE, a mineral consisting of gold and silver telluride, $AuAgTe_4$, containing gold 24·2 and silver 13·3%; an important ore of gold. Crystals are monoclinic and often very rich in faces; they are frequently twinned, giving rise to branching forms resembling written characters; on this account the mineral was early known as "graphic gold" or "graphic tellurium" (Ger. *Schrifterz*). It was also known as "white gold," the colour being

tin-white with a brilliant metallic lustre. The hardness is 2, specific gravity 8·2. It occurs with native gold in veins traversing porphyry at Offenbánya (=Baia de Arieş) and Nagyág (=Săcărâmb) in Transylvania (from which country it takes its name); also at several places in Boulder county, Colorado, and at Kalgoorlie in Western Australia. Sylvanite may be readily distinguished from calaverite, $AuTe_2$, by its perfect cleavage in one direction (parallel to the plane of symmetry), but in this character it resembles the very rare orthorhombic mineral krennerite ($[Au, Ag]Te_2$).

SYLVESTER, JOSHUA (1563–1618), English poet, the son of a Kentish clothier, was born in 1563. He was in 1591 in the service of the Merchant Adventurers' Company, and from 1606 had a small pension from Prince Henry. He was stationed, in his business capacity, at Middelburg, in the Low Countries, where he died on Sept. 28, 1618 He translated into English heroic couplets the scriptural epic of Guillaume du Bartas. His *Essay of the Second Week* was published in 1598; and in 1604 *The Divine Weeks of the World's Birth* Sylvester's popularity ceased with the Restoration, and Dryden called his verse "abominable fustian."

His works were reprinted by Dr. A. B Grosart (1880) in the "Chertsey Worthies Library" *See* also C Dunster's *Considerations on Milton's early Reading* (1800)

SYLVIIDAE: *see* WARBLER

SYLVITE, a mineral consisting of potassium chloride, KCl, first observed in 1823, as an encrustation on Vesuvian lava. Well-formed crystals were subsequently found in the salt deposits of Stassfurt in Prussia and Kałusz in Poland. It crystallizes in the cubic system with the form of cubes and cubo-octahedra and possesses perfect cleavages parallel to the faces of the cube. Although the crystals are very similar in appearance to crystals of common salt, they are proved by etching experiments to possess a different degree of symmetry, namely plagihedral-cubic, there being no planes of symmetry but the full number of axes of symmetry. Crystals are colourless (sometimes bright blue) and transparent; the hardness is 2, specific gravity 1·98. Like salt, it is highly diathermanous. The name sylvite or sylvine is from the old pharmaceutical name, *sal digestivus sylvii,* for this salt. (L. J. S.)

SYMBIOSIS, a mutually beneficial internal partnership between two organisms of different kinds, such as sea-anemone and unicellular algae. It differs from commensalism, where the partnership is external, as in the case of some hermit-crabs (e g, *Pagurus bernhardus*) which have as constant companions certain sea-anemones (e g, *Adamsia rondeletii*). It also differs from endoparasitism, which is not beneficial to the host; though it is possible that some symbionts or symbions, *e g*, the bacteria in the root-tubercles of Leguminosae, began as parasites; and that some parasites began as symbionts. The term mutualism is often used to cover both symbiosis and commensalism; and the term commensalism is sometimes used as equivalent to mutually beneficial symbiosis. This unnecessary confusion is increased when parasitism is called "antagonistic symbiosis."

The idea of symbiosis first became clear in regard to lichens, which were shown to be mutually beneficial combinations of an alga and a fungus This was demonstrated analytically by De Bary (1866) and others, while Rees and Stahl were subsequently successful in building up a lichen synthetically from the appropriate alga and fungus Symbiosis between two different plants is also illustrated by the numerous cases of mycorhiza (*q v*), where a fungus has entered into intimate and profitable partnership with the roots of other plants, such as oaks, pines and orchids Sometimes. as in the case of heather, the partner fungus spreads through the whole plant, from root to stem, from leaf to flower, and even into the seed. It is this partnership with a fungus that enables the heather to flourish on the soil of the moorland where few other plants can survive. This mycorhiza-relation is now known to be very common, and it occurs in various forms. Thus the fungus may be ectotrophic, investing the roots externally, as in the beech; or it may be endotrophic, penetrating into the internal tissue, as in orchids. Also symbiotic is the occurrence of tubercle-forming bacteria (e g., *Bacillus radicicola*) in the roots of leguminous plants, a linkage of great importance, inasmuch as the bacteria are able, in some way not yet clear, to capture and fix the free atmospheric nitrogen.

A second form of symbiosis is between an animal and an included unicellular green alga, such as *Zoochlorella.* The plant is sheltered, and it may be borne about by the animal, whose respiratory carbon dioxide it can utilize in its photosynthesis The animal profits by the oxygen given off by its minute partners, and it can also utilize the carbon-compounds which the algae build up. Some green animals—green because of the included algae—can flourish for a long time without any extraneous food, being sufficiently sustained by what their symbionts supply. Most animals of a green colour are green because of these partner-plants, many of which are included in the genera *Zoochlorella* and *Zooxanthella.* This was first made clear by Cienkowsky, Geddes and Brandt in regard to the "yellow cells" found inside radiolarians, whose symbiosis probably contributes to the great wealth of numbers and of species exhibited by these pelagic Protozoa. While there seem to be some Protozoa, such as euglenids and *Vorticella viridis,* which have chlorophyll corpuscles of their own, most of the green or greenish Protozoa, e g, *Stentor,* owe the colour to their symbionts The same is true for freshwater sponges, *Hydra viridis,* some sea-anemones, most reef-corals, numerous Alcyonarians, some Turbellarians, and a few higher forms, *e g*, a polyzoon and a sea-slug. Very interesting is the small turbellarian worm, *Convoluta roscoffensis,* which creeps from the sand and forms green patches on the flat beach at Roscoff, in Brittany, when the tide goes out. Its life has become intimately wrapped up with a symbiotic alga, one of the Chlamydomonadineae. As Keeble has well shown, there are four chapters in the history of *Convoluta* The very young worm feeds independently. Then green symbionts appear and multiply, and the worm is nourished from within as well as from without Thirdly *Convoluta* ceases to take any solid food and depends entirely on the photosynthetic activity of the symbions Finally, the animal digests its partners, and, having done so, dies

A third type of symbiosis, especially studied by Buchner, is seen in many insects where fungoid plants, *e g*, bacteria and yeasts, live in the lining cells of the food-canal and assist in some obscure way in the process of digestion These intracellular symbionts are known in at least seven orders of insects, especially in types that feed on dry wood and the like. The fungoid infection usually takes place in the egg-cell. In some cases there is a special organ or "mycetome" for the multiplication of the symbionts. In a few luminescent marine animals, *e g.*, some cuttlefish, (such as *Sepiola elegans*) there is considerable evidence that the light is produced by symbiotic bacteria.

A similar type of symbiosis is illustrated by the wood-eating species of termites, which have remarkable infusorians in their food-canal These are essential to the health of the termites which die when bereft of them. Their symbiotic function is to digest the wood, which no higher animal is able to do. Thus there may be symbiosis between plant and plant, between plant and animal, or between animal and animal

SYMBOL, the term given to a visible object representing to the mind the semblance of something which is not shown but realized by association with it. One of the first symbols of the Saviour, the fish, was derived from an acrostic of the Greek word ἰχθύς, the component letters of which were the initials of the five words Ἰησοῦς Χριστός, Θεοῦ Υἱός, Σωτήρ, Jesus Christ, Son of God, Saviour The ship, another early symbol, represented the Church, in which the faithful are carried over the sea of life. Other symbols are those which were represented by animals, real or fabulous, and were derived from Scripture: thus the lamb typified Christ from St. John's Gospel (i. 29 and 36), and the lion from the Book of Revelation, where (v. 5) Christ is called the "Lion of the tribe of Juda." The peacock stood for immortality; the phoenix for the Resurrection; the dragon or the serpent for Satan; the stag for the soul thirsting for baptism The

sacred monogram Chi Rho, ☧ supposed to have been the celestial sign seen by the emperor Constantine on the eve of the defeat of Maxentius, represents the two first letters of the Greek word Χριστός which Constantine figured on his labarum, or standard, and is found on early Christian coins bearing also the favourite decoration of the Byzantine sarcophagi.

SYMBOLISM: *see* PAINTING.

SYMBOLISTS, THE, the name given to a large but loosely connected group of French poets (many of them of foreign extraction) writing in the 1880's. The term *décadent* was often used as an alternative, especially of the extreme manifestations of the movement. In 1888 the critic Brunetière suggested that the history of French poetry from the 17th century could be plotted in three phases, the architectural, the pictorial and the musical. Bearing this programme in mind and taking as examples from his own literature Dryden's *Ode to Mistress Anne Killigrew,* Keats's *Ode on a Grecian Urn* and Tennyson's *Claribel,* the English reader will best understand the scope and extension of the Symbolist movement. In its origin the movement was a revolt against Naturalism as being too concrete, and against Parnassianism as being too clear-cut, to satisfy young minds who had caught from E. A. Poe and Baudelaire, from Wagner, and to some extent from the Pre-Raphaelites, the "sense of the ineffable" and were seeking a medium for its expression. Their object was not to declaim, not to depict, and least of all to transcribe, but to suggest: to communicate in their lost subtlety the most intimate and evanescent tones of experience. Baudelaire himself, Banville, Gérard de Nerval and Villiers de l'Isle Adam had already been engaged in the same quest. The common stock of poetic symbolism has been accumulated to serve common uses: a private symbolism, unless it is forced into currency by a great poet, is bound to be largely unintelligible and will often be suspected at least to be nonsense. It is not surprising therefore that the French public was at first half inclined to regard the new poetry as a hoax, and on the other hand to take seriously a volume of parodies *Les Déliquescences d'Adoré Floupette* (1885) which first made it popularly familiar. But in the meantime Verlaine had entered the circle; he gave it a watchword: "Pas de couleur, rien que la nuance," and in his book *Trois Poètes Maudits* introduced the young decadents to their true masters, Rimbaud, Corbière, Mallarmé. The year 1885 may be taken as the centre of the movement; besides the three already mentioned, Rodenbach, Verhaeren and Jean Moréas had then already appeared: Laforgue, H. de Régnier and Vielé Griffin published their first volumes in 1885, and they were followed by Rémy de Gourmont in 1886, Maeterlinck in 1889, Claudel in 1890, Robert de Montesquieu in 1893. With Samain's first volume in this last year the movement may be said to rejoin the main stream. Its principal representative, in prose, had been J. K. Huysmans: as poets, Rimbaud, Verlaine and Mallarmé, still after 40 years dominant influences in French literature. It was Mallarmé who provided the symbolists with their aesthetic theory and the most accomplished models of metric style, and in the whole course of the movement his weekly conversations were probably the most effective influence at work—an influence not unfelt in England, where it coincided with the aesthetic movement and the Celtic renascence.

SYME, JAMES (1799–1870), Scottish surgeon, was born in Edinburgh on Nov. 7, 1799. His chemical experiments at the university led to the discovery that a substance obtainable from coal tar would dissolve india-rubber, and could be used for waterproofing silk and other textile fabrics, an idea patented a few months afterwards by Charles Mackintosh, of Glasgow. From 1818 he held resident appointments in the infirmary and the fever hospital, and in 1823 took charge of the anatomy classes of Robert Liston. In 1824–25 he started the Brown Square school of medicine, and later a surgical hospital of his own, Minto House hospital, which he carried on from 1829 to 1833 with great success as a surgical charity and one of the first schools of clinical instruction. In 1833 he became professor of clinical surgery in the university, a post which he held until his acceptance of the chair of clinical surgery at University college, London, in 1847. Misunderstanding concerning the conditions of this appointment led him to return to his old position in Edinburgh, where he was recognized as the leading consulting surgeon of Scotland. In 1849 he broached the subject of medical reform in a letter to the lord advocate and in 1854 and 1857 addressed open letters to Lord Palmerston. In 1858 a Medical Act was passed which largely adopted his suggestions, and he became a member of the general medical council called into existence by the act. In April 1869 he had a paralytic seizure and died near Edinburgh on June 26, 1870.

Among Syme's labours may be mentioned his early papers on the nature of inflammation, his demonstrations of the function of the periosteum in the repair of bone, his introduction into Britain of excision of the elbow and of amputation at the ankle-joint, his treatment of ulcers by blistering, his study of diseases of the rectum and his general improvements in plastic surgery.

In 1831 he published *On the Excision of Diseased Joints* (the celebrated ankle-joint amputation is known by his name); in 1832 *Principles of Surgery; Diseases of the Rectum* in 1838; *Stricture of the Urethra and Fistula in Perineo* in 1849 and *Excision of the Scapula* in 1864; *Contributions to the Pathology and Practice of Surgery* in 1848 and *Observations in Clinical Surgery* in 1861.

See R. Paterson, *Memorials of the Life of James Syme* (1874).

SYMEON, "the Great," Bulgarian tsar (? –927) succeeded his father Boris (*q.v.*) in 893, after the short intervening reign of his dissolute elder brother, Vladimir. Educated in Constantinople, Symeon was probably destined by his father for the archbishopric of Bulgaria, and at one time took monastic orders.

His dominant ambition, himself to ascend the imperial throne of Byzantium—an aspiration afterwards shared by many Bulgarian tsars—led Symeon to embark on many wars with the empire (894, 896, 913, 917, 923). He never took Constantinople, although it was more than once at his mercy; but he took for himself the title of "Tsar of all the Bulgarians" (918) and raised the archbishop of Bulgaria to the rank of a patriarch. In the Balkans he extended the power of Bulgaria over south Macedonia, south Albania and Serbia, which became his vassal; but Bulgaria's shadowy dominion north of the Danube was probably lost during his reign. Symeon was twice married, and left four sons, of whom the second, Peter, succeeded him.

SYMEON METAPHRASTES, the most renowned of the Byzantine hagiographers. The menology of Metaphrastes, who is thought to have lived in the second half of the 10th century, is a collection of lives of saints for the twelve months of the year, consisting of about 150 distinct pieces, some of which are taken bodily from older collections, while others have been subjected to a new recension (μετάφρασις). Among other works attributed (though with some uncertainty) to Symeon are a *Chronicle,* a canonical collection, some letters and poems, and other writings of less importance. The Greeks honour him as a saint on Nov. 28, and an office has been composed in his honour.

See A. Ehrhard, *Die Legendensammlung des Symeon Metaphrastes* (Rome, 1897).

SYMMACHUS, QUINTUS AURELIUS (*c.* 345–410), was a brilliant representative of 4th-century paganism in Rome. He was educated in Gaul, and in 373 was pro-consul of Africa (for his official career see *C.I.L.* vi. 1699). His public dignities, which included that of pontifex maximus, his great wealth and high character, added to his reputation for eloquence, marked him out as the champion of the pagan senate against the Christian emperors. In 382 he was banished from Rome by Gratian for his protest against the removal of the statue and altar of Victory from the senate-house, and in 384, when he was prefect of the city, he addressed to Valentinian II. a letter praying for the restoration of these symbols. After this Symmachus was involved in the rebellion of Maximus, but obtained his pardon from Theodosius, and appears to have continued in public life up to his death. In 391 he was Consul ordinarius. His honesty, both in public and in private affairs, and his amiability made

him very popular. As his letters do not extend beyond the year 402, he probably died soon after that date.

Of his writings we possess: (1) *Panegyrics,* written in his youth, two on Valentinian I. and one on the youthful Gratian. (2) Nine books of Epistles. (3) Parts of *Complimentary Orations,* five from a palimpsest (also containing the *Panegyrics*), of which part is at Milan and part in the Vatican, discovered by Mai, who published the Milan fragments in 1815, the Roman in his *Scriptorum veterum nova collectio,* vol. i. (1825), and the whole in 1846. (4) The *Relationes,* which contain an interesting account of public life in Rome, composed for the emperor. All earlier editions are now superseded by that of O Seeck in *Monumenta Germaniae historica Auctores antiquissimi* (1883), vi. 1, with introductions on his life, works and chronology

SYMMACHUS, pope from 498 to 514, had Anastasius II. for his predecessor and was himself followed by Hormisdas. He was a native of Sardinia, apparently a convert from paganism, and was in deacon's orders at the time of his election. The choice was not unanimous, another candidate, Laurentius, having the support of a strong Byzantine party; and both competitors were consecrated by their friends, the one in the Lateran Church and the other in that of St Mary, on Nov. 22, 498. A decision was obtained in favour of Symmachus from Theodoric, to whom the dispute had been referred; but peace was not established until 505 or 506, when the Gothic king ordered the Laurentian party to surrender the churches of which they had taken possession. An important incident in the protracted controversy was the decision of the "palmary synod" The remainder of the pontificate of Symmachus was uneventful; history speaks of various churches in Rome as having been built or beautified by him.

SYMMETRIC FUNCTIONS: *see* EQUATIONS, THEORY OF.

SYMMETRY, due proportion of parts, in geometry, the metrical correspondence of parts with reference to a median plane or line or point; and, in algebra, the correspondence of terms in a function in such a way that the function is unaltered when any two variables on which it depends are interchanged. (*See* FUNCTION.) The word is derived from the Greek *συμμετρία, symmetri'a,* due proportion, from *σύν, syn,* with, and *μέτρον, metron,* measure. In botany it implies agreement in number and distribution of parts among the organs of a flower; and, in zoology, it implies symmetrical disposition of parts around a line in the body or on opposite sides of a plane through the body The term is also used with various derived meanings in architecture, aesthetics, crystallography, etc, and it appears even in certain ancient theories (as that of Herodotus, for instance) concerning the distribution of rivers, etc., on the earth.

SYMONDS, JOHN ADDINGTON (1840–1893), English critic and poet, was born at Bristol, on Oct. 5, 1840 He was the only son of John Addington Symonds, M D. (1807–71), and was educated at Harrow and at Balliol college, Oxford, where he won many distinctions. In 1862 he became a fellow of Magdalen. His health broke down under the strain of study, and he went to Switzerland to recuperate. There he met Janet Catherine North, whom he married in 1864. They lived at Clifton, where he lectured in the well-known schools. At Clifton he wrote his *Introduction to the Study of Dante* (1872) and his admirably vivid *Studies of the Greek Poets* (1873–76). Meanwhile he was occupied upon his *Renaissance in Italy* (7 vols., 1875–86), which remains a classic authority in English on its subject His work, however, was again interrupted by illness, and in 1877 his life was in acute danger He recovered at Davos Platz, and from that time onwards he practically made his home there.

His works written in his Swiss exile include biographies of Shelley (1878), Sir Philip Sidney (1886), Ben Jonson (1886), and Michelangelo (1893), several volumes of poetry and of essays, and a fine translation of the *Autobiography of Benvenuto Cellini* (1887). There, too, he completed his study of the *Renaissance,* the work by which he will be longest remembered. For many years he spent the autumn in the house of his friend, Horatio F. Brown, on the Zattare, in Venice He died at Rome on April 19, 1893, and was buried close to Shelley.

See Horatio F. Brown, *Life of John Addington Symonds* (from his letters) (2 vols, 1895), and V W Brooks, *Biographical Study of John Addington Symonds* (1914).

SYMOND'S YAT, one of the most famous view points on the river Wye, England. It stands on the river Wye 9 m. above Monmouth and 12 m. below Ross, on a deeply incised meander nearly 5 m. long and 600 yd. across the neck. The peninsula forms Huntsham Hill (Carboniferous limestone), in which there are caverns. The Yat or Gate is situated on the west side of the neck (height 500 ft.) and a road from the east drops to a ferry, which was of early importance. The Yat is in Herefordshire, but the railway station (G W.R) is in Gloucestershire. There are cottages and inns on both banks, New Weir is opposite the Yat and a little above it is Whitchurch, both small villages. The river banks are densely wooded, except where they become sheer cliffs, as at the Coldwell rocks above the station. The views from the Yat embrace the Forest of Dean to the south and east, and are backed by the mountains of the Welsh border in the west.

SYMONS, ARTHUR (1865–), English poet and critic, was born in Wales on Feb. 28, 1865, of Cornish parents. He was educated privately, spending much of his time in France and Italy. In 1884–86 he edited four of Quaritch's *Shakespeare Quarto Facsimiles,* and in 1888–89 seven plays of the "Henry Irving" Shakespeare. He became a member of the staff of the *Athenaeum* in 1891, and of the *Saturday Review* in 1894. His first volume of verse, *Days and Nights* (1889), consisted of dramatic monologues. His later verse is influenced by a close study of modern French writers (of Baudelaire, and especially of Verlaine) whose work he was one of the first Englishmen to appreciate and to introduce to English readers. He reflects French tendencies both in the subject-matter and style of his poems.

His volumes of verse include· *Silhouettes* (1892), *London Nights* (1895), *Amoris victima* (1897), *Images of Good and Evil* (1899), *A Book of Twenty Songs* (1905). In 1902 he made a selection from his earlier verse, published as *Poems* (2 vols). He translated from the Italian of Gabriele d'Annunzio *The Dead City* (1900) and *The Child of Pleasure* (1898), and from the French of Émile Verhaeren *The Dawn* (1898). To *The Poems of Ernest Dowson* (1905) he prefixed an essay on the deceased poet, who was a kind of English Verlaine and had many attractions for Symons. Among his volumes of collected essays are *Studies in Two Literatures* (1897), *The Symbolist School in Literature* (1899), *Cities* (1903), word-pictures of Rome, Venice, Naples, Seville, etc, *Plays, Acting and Music* (1903), *Studies in Prose and Verse* (1904), *Spiritual Adventures* (1905), *Studies in Seven Arts* (1906) His later works include. *Studies in Elizabethan Drama* (1920), *Charles Baudelaire* (1921); *Translations from Baudelaire* (1925); *A Study of Thomas Hardy* (1927); *Studies in Strange Souls* (*Rossetti and Swinburne*) (1929).

See T. E. Welby, *Arthur Symons, A Critical Study* (1925) pp 147.

SYMPATHETIC SYSTEM, in physiology. By the "sympathetic system" is understood a set of nerves and ganglia more or less sharply marked off from the cerebro-spinal, both functionally and anatomically. (For anatomy *see* NERVOUS SYSTEM.) Formerly it was thought more independent from the rest of the general nervous system than recent discoveries have found it actually to be. The sympathetic system is now known to consist entirely of conducting paths which, like the nerve-trunks of the cerebro-spinal system, merely conduct nerve impulses either toward the great nervous centres of the spinal cord and brain, or, on the other hand, away from those great centres. In the cerebro-spinal nerves the preponderance of the conduction is toward the centres, in the sympathetic system the preponderance of conduction is away from the centres

More is known of the sympathetic system from its efferent aspect than its afferent, and we shall consider the former first. One great difference between the efferent paths of the sympathetic and those of the ordinary cerebro-spinal system is that the former carry nervous impulses not only to muscular tissue but to secreting glands, whereas the latter convey them to muscle only, indeed only to muscle of the striated kind. Another difference is that the efferent path which the sympathetic affords from the great central nervous centres to its muscles and glands consists always of *two* nerve-cells or neurones, whereas the efferent path afforded by the cerebro-spinal motor nerves consists of one neurone only. The two neurones forming the sympathetic path are so arranged that one of them whose cell-body lies in the spinal cord has a long axon-process passing out from the cord in the motor spinal

root, and this extends to a group of nerve-cells, a sympathetic ganglion, quite distant from the spinal cord and somewhere on the way to the distant organ which is to be innervated. In this ganglion the first sympathetic neurone ends, forming functional connection with ganglion cells there. These ganglion cells extend each of them an axon-process which attains the organ (muscular cell or gland cell), which it is the office of the sympathetic path to reach and influence. The axon-process of the first nerve cell is a myelinated nerve-fibre extending from the spinal cord to the ganglion; it constitutes the pre-ganglionic fibre of the conduction chain. The axon-process of the second nerve-cell, that is the neurone whose bell-body lies in the ganglion, is usually non-myelinate and constitutes the post-ganglionic fibre of the chain.

This construction, characteristic as it is of the sympathetic efferent path, has been found also in certain other efferent paths outside the sympathetic proper. And as these other efferent paths convey impulses to the same kind of organs and tissues as do those of the sympathetic itself, it has been proposed to embrace them and the sympathetic under one name, the *autonomic* system. This term includes all the efferent paths of the entire body excepting only those leading to the voluntary muscles.

That the term "autonomic system" is not merely a convenience of nomenclature, but really represents a physiological entity, seems indicated by the action of nicotine. This drug acts selectively on the autonomic ganglia and not on the cerebro-spinal. In the former it paralyses the nexus between pre-ganglionic and post-ganglionic fibre. It is by taking advantage of this property that many of the recent researches which have done so much to elucidate the sympathetic have been executed.

The term "autonomic system" must not be taken to imply that this system is independent of the central nervous system. As mentioned above in regard to the sympathetic, that is not the case. The autonomic system is closely connected with the central nervous system through the ordinary channel of the nerve-roots, spinal and cranial. It may, in fact, be regarded as an appendage of certain of the cranial and spinal roots.

The sympathetic is that part of the autonomic system which is connected with the spinal roots from the second thoracic to the second lumbar inclusive (man). Its ganglia are divided by anatomists into the vertebral, those which lie as a double chain on the ventral face of the vertebral column, and those which lie scattered at various distances among the viscera, the pre-vertebral. Langley has shown that there is no essential difference between these except that the vertebral send some of their post-ganglionic fibres into the spinal nerves, whereas the latter send all their fibres to the viscera. The sympathetic sends its post-ganglionic fibres—

1. To the muscular coats of the whole of the alimentary canal from the mouth to the rectum; to the glands opening into the canal from the salivary glands in front back to the intestinal glands; to the blood vessels of the whole of the canal from mouth to anus inclusive.

2. To the generative organs, external and internal, and to the muscular coats of the urinary bladder.

3. To the skin; (*a*) to its blood vessels; (*b*) to its cutaneous glands; (c) to unstriated muscle in the skin; *e.g.*, the erectors of the hairs.

4. To the iris muscles and blood vessels of the eyeball.

The sympathetic nervous system is sometimes called the visceral. It will be seen from what has been said that this term is not well suited in some respects, because the sympathetic supplies many structures which are not visceral. Another objection is that a great deal of important nerve-supply to the viscera is furnished by parts of the autonomic system other than sympathetic. That the sympathetic does, however, of itself constitute a more or less homogeneous entity is indicated by a curious fact. The substance adrenalin has the property, when introduced into the circulation of exciting all over the body just those actions which stimulation of the efferent fibres of the sympathetic causes, and no others. It is possible that when a nerve is stimulated some body at the nerve ending is set free, and this by combining with another chemical substance induces activity in the end organ (gland or muscle). It may be that when a sympathetic nerve is excited adrenalin is set free and combines with some substance which induces activity. (*See* ADRENALIN; SUPRA-RENAL EXTRACT.)

The rest of the autonomic system consists of two portions, a cranial and a sacral, so called from their proceeding from cranial and sacral nerve-roots respectively. The cranial portion is subdivided into a part belonging to the mid-brain and a part belonging to the hind-brain. The ciliary ganglion belonging to the eyeball is the ganglion of the former part, and its post-ganglionic fibres innervate the iris and the ciliary muscles. The hind-brain portion gives pre-ganglionic fibres to the facial (intermedius), glossopharyngeal and vagus nerves; its post-ganglionic distribution is to the blood vessels of the mucous membrane of the mouth and throat, to the musculature of the digestive tube from the oesophagus to the colon, to the heart, and to the musculature of the windpipe and lungs.

The sacral part of the autonomic system issues from the spinal cord with the three foremost sacral nerves. Its ganglia are scattered in the neighbourhood of the pelvic organs, which they innervate. The distribution of its post-ganglionic fibres is to the arteries of the rectum, anus and external genitalia and to the musculature of the colon, rectum, anus, bladder and external genitalia.

The part played by the sympathetic and the rest of the autonomic system in the economy of the body is best considered by following broad divisions of organic functions.

Movements of the Digestive Tube.—It is those movements of alimentation not usually within range of our consciousness which the autonomic system regulates and controls. Nor is its control over them apparently essential or very complete. For instance, the pendular and peristaltic movements of the intestine still go forward when all nerves reaching the viscus have been severed. Extirpation of the abdominal sympathetic has not led to obvious disturbance of digestion or nutrition in the dog. It is noteworthy that the sympathetic inhibits contraction of the musculature of the stomach and intestine, while the other, the vagus, portion of the autonomic system excites it.

Action on the Circulation.—The arterial blood supply of most organs is under the control of vaso-constrictor nerves. All vaso-constrictor nerves are sympathetic. Organs to which vaso-constrictor nerves are supplied either poorly or not at all are the lungs, heart, liver and probably the skeletal muscles. In some parts the capillary vessels are supplied with sympathetic constrictor nerves. The blood vessels of certain parts of the body have, in addition to vaso-constrictor nerves, nerves which relax their muscular wall, vaso-dilatory nerves. The latter are never furnished by the sympathetic, they are in the mucous membranes and glands at the oral end of the body furnished by the cranial portion of the autonomic system. In regions at the aboral end of the body they are furnished by the sacral portion of the autonomic system. Elsewhere the vaso-dilatators when present are derived from the nerve-cells of the spinal ganglia (Bayliss).

The control of the calibre of the blood vessels by the autonomic system is of importance in several well-ascertained respects. By constricting the blood vessels of the viscera the system is able to favour an increase of blood supply to the brain. A noteworthy instance of such an action occurs when the erect attitude is assumed after a recumbent posture. Were it not for vaso-constriction in the abdominal organs the blood would then, under the action of gravity, sink into the more dependent parts of the body and the brain would be relatively emptied of its supply, and fainting and unconsciousness result. Again, it is essential to the normal functioning of the organs of warm-blooded animals that their temperature, except in the surface layer of the skin, should be kept constant. Part of the regulative mechanism for this lies in nervous control of the quantity of blood flowing through the surface sheet of the skin. That sheet is a cool zone through which a greater or smaller quantity of blood may, as required, be led and cooled. By the sympathetic vaso-constrictors the capacity of these vessels in the cool zone can be reduced, and thus the loss of heat from the body through that channel les-

sened. In cold weather the vaso-constrictors brace up these skin vessels and lessen the loss of heat from the body's surface. In hot weather the tonus of these nerves is relaxed and the skin vessels dilate; a greater proportion of the blood then circulates through the comparatively cool skin-zone.

The heart itself is but a specialized part of the blood-vascular tubing, and its musculature, like that of the arteries, receives motor nerves from the sympathetic. These nerves to the heart from the sympathetic are known as the accelerators, since they quicken and augment the beating of the cardiac muscle. The heart receives also nerves from the cranial part of the autonomic system, and the influence of these nerves is antagonistic to that of the sympathetic supply. The cranial autonomic nerves to the heart pass via the vagus nerves and lessen the beating of the heart both as to rate and force. These inhibitory nerves of the heart are analogous to the dilatator nerves to the blood vessels, which, as mentioned above, come not from the sympathetic, but from the cranial and sacral portions of the autonomic system The spleen which functions as a blood-reservoir (Barcroft) for the general circulation, discharges its reserves by contraction of its capsule and septa; its muscle is innervated by the sympathetic.

Skin-glands.—In close connection with the temperature regulating function of the sympathetic stands its influence on the sweat secreting glands of the skin. Secretory nerves to the sweat glands are furnished apparently exclusively by the sympathetic.

Pilomotor Nerves.—The skin in many places contains muscle of the unstriped kind. Contraction of this cutaneous muscular tissue causes knotting of the skin as in "goose-skin," and erection of the hairs as in the cat, or of the quills as in the hedgehog and porcupine. The efferent nerve-fibres to the unstriped muscles of the skin are always furnished by the sympathetic (pilomotor nerves, etc). In this case the sympathetic contributes to emotional reactions and perhaps further to the regulation of temperature, as by ruffling the fur or feathers in animals exposed to the cold.

The Respiratory Tube.—The windpipe and the air passages of the lungs contain in their walls much unstriped muscular tissue, arranged so as to control the calibre of the lumen. The nerve-supply to this muscular tissue is furnished by the cranial autonomic system via the vagus nerves.

Eyeball.—An important office of the sympathetic is the controlling of the brightness of the visual image by controlling the size of the pupil. The sympathetic sends efferent fibres to the dilatator muscle of the pupil. In this case, as in others noted above, the cranial part of the autonomic system sends nerves of antagonistic effect to those of the sympathetic, first through the third cranial nerves from the efferent fibres to the constrictor muscle of the pupil. This same part of the cranial autonomic system supplies also motor fibres to the ciliary muscle, thus effecting the accommodation of the lens for focusing clearly objects within the range of what is termed near-vision.

Of the afferent fibres of the sympathetic little is known save that they are, relatively to the efferent, few in number, and that they, like the afferents of the cerebro-spinal system, are axons of nerve-cells seated in the spinal ganglia. (C. S. S)

SYMPHONIC POEM (*Symphonische Dichtung, Tondichtung, Poème symphonique,* etc.). This term was first used by Liszt in his 12 *Symphonische Dichtungen.* It implies a large orchestral composition which, whatever its length and changes of tempo, is not broken up into separate movements, and which, moreover, gratuitously illustrates a train of thought external to the music and to its conditions of performance. The form of the symphonic poem is dictated by its written or unwritten programme; and so it is not every piece of "programme music" that can be called a symphonic poem. Beethoven's sonata "Les Adieux" and his "Pastoral Symphony" are, for instance, works in which the poetic idea does not interfere with the normal development of sonata style.

Great disturbances in musical art have always been accompanied by appeals to external ideas. New art-forms are not born mature, and in their infancy their parent arts naturally invite other arts to stand godfather. It is certain, first, that no theorizing can long prevent musical ideas from growing where and how they please; secondly, that musical ideas are just as likely to be inspired by literature and other arts as by any other kind of experience; and lastly, that, as musicians gain in mastery, their music outstrips their literary analysis. Hence the frequent ability of great composers to set inferior words to music which is not only great, but evidently based upon those words Hence the disgust of great composers at unauthorized literary interpretations of their works. Hence, on the other hand, the absence of any strain on the classical composer's conscience as to making his music gratuitously illustrative. Accordingly, the importance of the symphonic poem lies, not in its illustrative capacity, but in its tendency towards a new instrumental art of to-morrow.

The symphonic poem has been described elsewhere (*see* MUSIC, section 9, and PROGRAMME MUSIC) as the application of the Wagnerian time-scale to symphonic music. Liszt is successful only where he is writing on a hardly more than lyric scale, as in *Orpheus,* or, at the utmost, on a scale less than that of the earliest and best of all symphonic poems, Schubert's Wanderer Fantasia (op. 15). Schubert had not the slightest idea that he was writing a symphonic poem; but in that piece he achieved everything that Liszt attempted, even to the metamorphosis of whole sections. Liszt's efforts on a larger time-scale do not even begin to solve the problem; they achieve no sense of movement at all, and the device of deriving all their themes from a single figure is totally irrelevant. Saint-Saëns and César Franck are incapable of such failure, and their symphonic poems flow very convincingly, though not on a very large scale They also illustrate their subjects amusingly enough. The first achievement of real Wagnerian symphonic art belongs to Richard Strauss. The power of composition in his *Also sprach Zarathustra, Ein Heldenleben,* the ostentatiously but deceptively patchy *Don Quixote,* and the *Symphonia Domestica,* will carry conviction long after we have forgotten all about their programmes. (D. F T)

SYMPHONY, in music. (1) The term συμφωνία was used by the Greeks, first, to denote concord, in general, whether in successive or simultaneous sounds; secondly, in the special sense of concordant pairs of successive sounds (*i.e.,* the "perfect" interval of modern music; the 4th, 5th and octave); and thirdly, as dealing with ἀντιφωνον, the concord of the octave, thus meaning the art of singing in octaves, or *magadizing,* as opposed to ὁμοφωνία, or singing and playing in unison. In Roman times the word appears in the general sense, which still survives in poetry, viz., as a harmonious concourse of voices and instruments. It also appears to mean a concert. In St. Luke xv 25, it is distinguished from χόροι and translated as signifying "music and dancing" Polybius and others seem to use it as the name of a musical instrument.

(2) In the 17th century the term is used, like "concerto," for certain vocal compositions accompanied by instruments, *e.g.,* the *Symphoniae sacrae* of Schutz. The modern use of the word symphony for the instrumental ritornello of a song is also found in Schütz's *Kleine geistliche Concerte.*

(3) The principal modern meaning of the word is a sonata for orchestra (*see* SONATA FORMS). The orchestral symphony originated in the operatic overture (*q.v.*), which in the middle of the 18th century began to assimilate the essentials of the sonata style. Mozart's overture to his early opera, *La Finta Giardiniera,* marks the breaking-point between three-movement symphony and operatic overture, since it contains the usual first movement and slow movement, and the curtain rises with what sounds like the beginning of its third movement.

Though the sonata style is dramatic the stiffness of its early forms did not help Gluck towards his ideal of an overture that should prepare the listener for the drama. Hence the overtures of Gluck are based on the contrast of loosely knit passages of various textures in vague forms which he learned from San Martini. These are no less evident in the symphonies of Philipp Emmanuel Bach.

The differentiation between symphony and overture raised the dignity of the symphony; but the style was more essential than the form; and in Mozart's and Haydn's mature works we

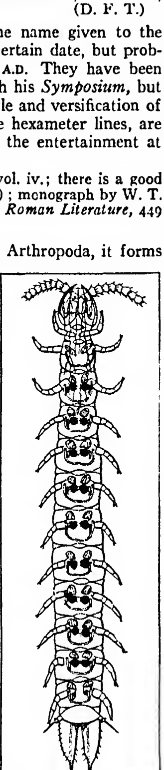
find the sonata form as firmly established in the overture as in the symphony, while the styles are quite distinct. Mozart's most elaborate overture, that of *Die Zauberflöte,* could not possibly be the first movement of one of his later symphonies; nor could the finale of his "Jupiter" symphony be taken for a prelude to an opera.

See also MUSIC; SONATA FORMS; INSTRUMENTATION; OVERTURE; SCHERZO; VARIATIONS. (D. F. T.)

SYMPHOSIUS or **SYMPOSIUS,** the name given to the author of a collection of 100 riddles of uncertain date, but probably composed in the 4th or 5th century A.D. They have been attributed to Lactantius, and identified with his *Symposium,* but this view is not generally accepted. The style and versification of the riddles, each of which consists of three hexameter lines, are good. They were written to form part of the entertainment at the Saturnalia.

Text in E. Bährens, *Poetae latini minores,* vol. iv.; there is a good French metrical version by E. F. Corpet (1868); monograph by W. T. Paul (Berlin, 1854); *see* also Teuffel, *Hist. of Roman Literature,* 449 (Eng. trans., 1900).

SYMPHYLA. A class of soil-dwelling Arthropoda, it forms with Diplopoda (Millipedes, *q.v.*) and Pauropoda (*q.v.*) the super-class Progoneata.



FROM VERHOEFF IN "DIPLOPODA," BRONN. "KLASSEN UND ORDNUNGEN DES TIER-REICHS" (AKEDEMISCHE VERLAGSGESELLSCHAFT)

A SYMPHYLE, (SCOLOPENDRELLA IMMACULATA), SHOWING LOWER SURFACE AND A FEW OF THE BASAL JOINTS OF THE ANTENNAE

Symphyla comprise but one family, the Scolopendrellidae.

The white body, never more than eight millimetres long, is invested with thin chitin and consists of a distinct head with one pair of many jointed antennae and an elongated trunk bearing twelve pairs of legs, of which the first is often much reduced. At the hind end of the body are a pair of backwardly directed conical appendages, the cerci, which function as spinning organs.

Symphyla have been described from all the continents of the globe. They are occasionally injurious to the delicate tissues of cultivated plants.

See C. Attems, "Symphyla" in *Handbuch der Zoologie,* vol. 4, p. 11 (1926). On economic status *see* J. Feytaud, *Revue de Zoologie Agricole, Bordeaux,* Sept. 1925, p. 192.

SYNAGOGUE, denotes either a congregation of Jews (συναγωγή lit. "assembly"), or their place of worship, or, more generally, Judaism as contrasted with Christianity; the last sense is exemplified by the famous pair of statues, Church and Synagogue, in the porch of Strasbourg cathedral. (Illustrations and explanation of the allegory on pp. xii., xxxvi. of *Legacy of Israel,* 1927.) The usual Hebrew term for synagogue is כְּנֶסֶת or בֵּית־הַכְּנֶסֶת (*Keneseth* or *Beth hak-Keneseth*): in Ps. lxxiv., 8, מוֹעֲדֵי־אֵל (assemblies of God) is assumed to refer to synagogues. There can be no doubt but that the synagogue, Ezra's main work, grew up with the Temple and developed from it. By the time of the fall of the Temple, synagogues were well established, for differences of synagogal and Temple liturgy are known and when the Temple fell, the synagogue remained unaffected: it had long become an independent institution. The synagogue was the place of study: the law was read on Sabbaths (Acts xv., 21), Festivals and market days in an annual, and also in a triennial cycle (on this *see* articles in *Jew. Quart. Rev.* by A. Büchler [v. 420–68: vi., 1–73] and by J. Abrahams [xvi., 579–83] and "Triennial Cycle" in *Jew. Enc.*). The lessons from the Pentateuch were translated by a *Meturgemān* or translator (from the same root as *Targūm* and dragoman *qqv.*): lessons from the prophets (see *Haftāra*) concluded the service, in which preaching and exposition were included. On Jesus and the synagogue, *see* I. Abrahams (*Studies,* I. 1, 1917).

The synagogue was not limited to Palestine, it has, in fact, been termed the "child of the dispersion," but this does not imply that it was the product of the Hellenic diaspora exclusively. In Egypt there are references to three altars or temples, that at Assouan in the 5th cent. B.C., which Cambyses spared when he invaded the country (on this *see* A. Cowley's *Aramaic Papyri* [Oxford, 1923], especially p. 113); the altar and the pillar named in Is. xix., 19; and the Onias Temple built at Leontopolis about 154 B.C. (on this *see* S. A. Hirsch, pp. 39 *sqq.* in *Jews' Coll. Jub. Vol.;* London, 1906). It is most unlikely that at these sacred places, services were not held. Congregations existed in most parts of the Roman empire. Acts xv., 21, speaks of "synagogues in every city from generations of old": from Cicero's *Pro Flacco,* the rich contributions to the Temple in 62 B.C. from the synagogues of Apamea, Laodicea and Pergamon—towns in Asia Minor—are known. Under the term Proseuche (προσευχή place of prayer), Roman authors speak of synagogues, and their allusions show that these places were common. The officials of the synagogue were the ἀρχισυνάγωγοι Luke xiii., 14; Acts xiii., 15; the *gabbā'im* or treasurers who collected charitable contributions in cash and kind (*Quppāh and Ṭamhui*); the ὑπηρέτης (Luke xiii., 14) or *Ḥazzān* (lit. overseer, ἐπίσκοπος) a teacher, reader or beadle who inflicted scourging (*Malqūth,* Matt. x., 17) when decreed by the elders (πρεσβύτεροι, γερουσία) through their ἄρχοντες or chief members. Major disciplinary punishments were excommunication (*Ḥērem*) and exclusion (*Niddui*). The ancient Galilean synagogues ran north and south (modern buildings are orientated) and possessed a nave and twin aisles.

BIBLIOGRAPHY.—On the synagogue generally *see* the various articles on synagogue liturgy, etc., in *Jew. Enc.* and Hastings *D.B.* and *E.R.E.* On the internal and external architecture *see* numerous illustrations in *Jew. Enc.* under the names of towns with famous synagogues: W. G. Tachau, *Architecture of Syn.* (numerous illustrations), in *Am. Jew. Year Book,* vol. 28 (1926); H. Kohl and C. Watzinger, *Antike Syn. in Galilaea* (1916). On the ancient "Men of the Great Synagogue" *see* excursus ii. in Taylor, *op. cit. sup.*

SYNAPSE, the functional conjunction between two neurons, making conduction of nervous impulses continuous from one to the other. Synapses occur between the axone terminations of one neuron, and the cell body of an adjacent cell. This type of synapse is called axo-somatic. Synapses also occur between axone terminations of one neuron and the dendrites of the next, and are then termed axo-dendritic. Adjacent neurons may be connected by both types of synapse. There are two theories of the actual cell structures participating in the synapse, the contact theory and the continuity theory. The contact theory, which is most generally accepted, holds that a nerve impulse in passing from one neuron to another traverses the neurofibrils, the perifibrilar substance and the cell membrane of the axone of the first neuron; possibly a glious intercellular substance; and finally the cell membrane, the perifibrilar substance and the neurofibrils of the second neuron receiving the impulse. The continuity theory holds that minute protoplasmic threads establish neurofibrilar continuity between the adjacent cells. A number of very important phenomena of nerve conduction are attributable to the synapse; among them irreversibility of direction, after discharge, slower speed of conduction, fatigability, temporal summation, inhibition, facilitation and increased susceptibility to drugs. (*See* NEURON; CONSCIOUSNESS, PSYCHOLOGY OF.) (W. M. M.)

SYNCRETISM, the act or system of blending, combining or reconciling inharmonious elements. The term is used technically in politics, as by Plutarch, of those who agree to forget dissensions and to unite in the face of common danger, as the Cretans were said to have done; in philosophy, of the efforts of Cardinal Bessarion and others in the 16th century to reconcile the philosophies of Plato and Aristotle; and in theology, of a plan to harmonize the hostile factions of the Church in the 17th century, advocated by Georg Calixtus, a Lutheran professor of theology at Helmstadt. Its most frequent use, however, is in connection with the religious development of antiquity, when it denotes the tendency, especially prominent from the 2nd to the 4th centuries of

the Christian era, to simplify and unify the various pagan religions. During this period, as a result of the intimate knowledge of the world's religions made possible by the gathering of every known cult of importance into the religious system of the Roman Empire, belief in the identity of many deities which resembled each other, and indeed in the essential identity of all, received a special impulse. Not only were various forms of the same deity, such as, for example, Jupiter Capitolinus and Jupiter Latiaris, recognized as being really the same under different aspects, but even the gods of different nations were seen to be manifestations of a single great being. Roman Jupiter, Greek Zeus, Persian Mithras and Phrygian Attis were one. The Great Mother, Isis, Ceres, Demeter, Ops, Rhea, Tellus, were the same great mother deity under different masks (*see* GREAT MOTHER OF THE GODS). Venus and Cupid, Aphrodite and Adonis, the Great Mother and Attis, Astarte and Baal, Demeter and Dionysus, Isis and Serapis, were essentially the same pair. Syncretism even went so far as to blend the deities of paganism and Christianity. Christ was compared with Attis and Mithras, Isis with the Virgin Mary, etc. Isis, perhaps more than any other deity, came to be regarded as the great maternal goddess of the universe whose essence was worshipped under many different names.

Naturally, the influence of Greek philosophy was very pronounced in the growth of syncretism Plutarch and Maximus of Tyre affirmed that the gods of the different nations were only different aspects of the same deity, a supreme intelligence and providence which ruled the world. The Neoplatonists, however, were the first school to formulate the underlying philosophy of syncretism: "There is only one real God, the divine, and the subordinate deities are nothing else than abstractions personified, or celestial bodies with spirits; the traditional gods are only demons, that is, beings intermediate between God and man. . . . All, like every other created being, are emanations from the absolute God" (Jean Réville, *La Religion à Rome sous les Sévères*). Care must be taken, however, not to place too much emphasis upon syncretism as a conscious system. The movement which it represented was not new in the 2nd century A.D. The identification of Latin with Etruscan gods in the earliest days of Rome, and then of Greek with Italian, and finally of Oriental with the Graeco-Roman, were all alike syncretistic movements, though not all conscious and reasoned The ideal of the common people, who were unreflecting, as well as of philosophers who reflected, was "to grasp the religious verity, one and constant, under the multiplex forms with which legend and tradition had enveloped it" (Réville). The advent of Greek philosophy only hastened the movement by conscious and systematic effort.

Syncretism, being a movement toward monotheism, was the converse of the tendency, so prominent in the early history of Rome, to increase the number of deities by worshipping the same god under special aspects according to special activities. In the hands of the Neoplatonists it was instrumental in retarding somewhat the fall of paganism for the time, but in the end contributed to the success of Christianity by familiarizing men with the belief in one supreme deity.

See Jean Réville, *op. cit.*, especially pages 104–127, 159–174, 284–295. For other examples of syncretism, *cf.* that of Buddhism Zoroastrianism in the state religion of the Indo-Scythian kingdom of Kanishka (*see* PERSIA: *Ancient History*, "The Parthian Empire"); *see* articles on almost all the religions of the East, *e.g*, MITHRAS; ZOROASTER.

(G. S.)

SYNDERESIS, a term in scholastic philosophy applied to the inborn moral consciousness which distinguishes between good and evil. The word is really *synteresis* (Gr. *συντήρησις,* from *συντηρεῖν,* to look after, take care of), but synderesis is the commoner form. Diogenes Laërtius in his account of the Stoics uses the phrase *τηρεῖν ἑαυτό* to describe the instinct for self-preservation, the inward harmony of Chrysippus, the recognition of which is *συνείδησις.* The term *synderesis,* however, is not found till Jerome, who in dealing with Ezek. i. 4–15, says the fourth of the "living creatures" of the vision is what the Greeks call *συντήρησις, i.e., scintilla conscientiae* the "spark of conscience." Here apparently synderesis and conscience (*συνείδησις*) are equivalent. By the schoolmen, however, the terms were differentiated, conscience being the practical envisaging of good and evil actions; synderesis being, so to speak, the tendency toward good in thought and action. The exact relation between the two was, however, a matter of controversy, Aquinas and Duns Scotus holding that both are practical reason, while Bonaventura narrows synderesis to the volitional tendency to good actions.

SYNDICALISM. "Syndicalism" is the name given to a form of socialist doctrine elaborated by, and born from the experience of, the members of the French *syndicats* or trade unions. The French word *syndicalisme* means originally no more than trade unionism and is still frequently used in that restricted sense Syndication before the World War was a doctrine of wide influence, but it has now largely been absorbed within the Communist Parties or other organizations. On the one hand it is a body of social doctrine or theory of social organization; on the other it is a plan of action for the realization of this ideal. Of all the social theories competing for existence it is the most purely proletarian in origin. One writer indeed has described it as "working-class socialism" (*le socialisme ouvrier*) in contradistinction to the types of socialism originated and propagated by middle-class "intellectuals."

The syndicalist starts from the assumptions common to most schools of socialist thought. He affirms the inherent injustice of the wage system and the fundamental immorality of capitalist society, which is based, in his belief, on the exploitation of labour. He accepts and pushes to its logical conclusion the Marxian dogma of the class war; he therefore affirms that solidarity of interests does not, and cannot, exist as between employer and employed, between capitalist and wage-earner. From these premises he draws the usual socialist conclusion, namely, that individual ownership of the instruments of production must be abolished and communal ownership and control substituted for it. But at this point syndicalism and socialism (as usually understood) part company Whereas the orthodox socialist demands control by the consumers acting through the State and its dependent organs such as the municipalities, the syndicalist demand, until very recently, was for producers' control, acting through the organizations of their own creation—the trade unions.

State organization and control of industry are, in their view, incompatible with true working-class emancipation The State is, and must be, an instrument of class domination; it is indeed "the executive committee of the capitalist class." It exists to defend the interests of that class, and is consequently as much the enemy of labour as capital itself. To extend its powers would be to twine the bonds of wage slavery ever more firmly about the workers' limbs. The State is, moreover, hopelessly wedded to an uncreative bureaucracy, incapable of initiative and ignorant of industrial technique. Its control, even if it were benevolent (which the syndicalist denies it could be), would necessarily be despotic and inefficient; the spirit of routine would combine with inexperience to crush out the possibility of economic progress. Here, as will be seen, the syndicalist endorses the ordinary individualistic criticism of State socialism. Producers' control, exercised through the *syndicats,* would combine freedom with efficiency.

The form of social organization in which this ideal could be realized was, until recently, conceived somewhat as follows: The unit of organization would be the local *syndicat.* This would be brought into touch with the local groups by means of the *Bourse du Travail,* the present function of which is to act at once as an employment agency and a general centre for trade-union activities. When all the producers were thus linked together by the *bourse,* the administration of the latter would be able to estimate the economic capacities and necessities of the region, could co-ordinate production, and, being in touch through other *bourses* with the industrial system as a whole, could arrange for the necessary transfer of materials and commodities, inwards and outwards. A species of "economic federation" would thus replace the structure of capitalist industry, with which would necessarily disappear the political and administrative machinery of the State. Two features of this Utopia need to be emphasized; consumers as such were excluded from any share in industrial control, and a localized system of industry was envisaged. This latter feature was a direct

reflection of French economic circumstances; both industry and trade-unionism were much more local in range than in other and more highly developed countries. But the movement towards large-scale organization which has so profoundly affected every aspect of economic life in recent years has produced a corresponding modification in syndicalist ideals. At the same time it has begun to be recognized by the theorists of the movement that the consumers' point of view cannot wholly be disregarded.

Syndicalist theory starts, as has been said, from the idea of a class war which must be waged relentlessly till a complete social transformation has been accomplished. The essential weapon in this struggle is the power of the organized workers. As the cause of the conflict is economic it must necessarily be fought out in the economic sphere. Syndicalist congresses have persistently repudiated political action and pinned their faith to a general strike as the grand instrument of social revolution. This reliance upon industrial or "direct" methods of action flows necessarily from the fundamental notions of syndicalism as to the nature of the State, and also from strictly practical considerations. Outside the mine or factory, working men hold divergent religious or political opinions which make effective mass action difficult, if not impossible. Inside, the nature of their employment gives them a sense of solidarity which overrides minor differences and bands them together in the *syndicat* for common defence; to persuade them to pass from the defensive to the offensive is the syndicalist's task, and in the accomplishment of this political labels and controversies would be a hindrance. The strike, therefore, is the characteristic syndicalist weapon. However limited in its scope and object, it is an educative experience; successful, it inspires the workers with a sense of power; unsuccessful, it impresses upon them the servility of their lot and the necessity for better organization and wider aims. Thus every strike is a preparation for the revolutionary "day," when the workers, or a fighting minority of them (for syndicalism repudiates as *bourgeois* the dogma of the sacredness of majority rule), shall seize the instruments of production by an "expropriatory" strike. In the meantime, they are working out from day to day, in the ordinary course of their employment, the ethics and the jurisprudence of the new social order.

The strike, of course, is not the only weapon in the syndicalist armoury. Various other means of waging the class war, known collectively as *sabotage,* are both preached and practised. These range from bad or slow work to the *grève perlée* (destruction of goods or machinery) and the *chasse aux renards* (assaults on "black-legs" or *jaunes*). It is fair to say that many syndicalist leaders criticize these methods as destructive of the worker's *moral* and technical competence.

Syndicalism is essentially French in origin and reflects French working-class experience and conditions of life; nevertheless the history of Great Britain shows interesting foreshadowings of it. The idea of industrial self-government by the producers attracted for a time the mobile mind of Robert Owen; and the Grand National Consolidated Trades Union of 1834 was an attempt to realize it in practice. James Morrison, a young, self-taught operative builder, seems to have originated the syndicalist conception of class antagonism on the part of the working-classes. The Operative Builders' Union had developed the same notion in the previous year. The plan of a general strike—originated by one Benbow—for a time, under the strange title of the "Sacred Month," made part of Chartist propaganda. There is no evidence, however, that these projects had any echo on the European continent. The syndicalist idea, as understood in France, may be said to have originated in the discussions of the International Working Men's Association. A French delegate to the Congress of Basle in 1869, for instance, prophesied that "the grouping of different trades in the city will form the commune of the future" when "government will be replaced by federated councils of *syndicats* and by a committee of their respective delegates regulating the relations of labour—this taking the place of politics." These tendencies manifested themselves with increasing strength during the '90s in the two great labour organizations of the period—the General Confederation of Labour (or "C.G.T." under its French initials) and the Federation of *Bourses du Travail.* The secretary of this latter organization, Pelloutier, did more perhaps than any other individual to work out the characteristic doctrines of syndicalism and spread them among his fellow-workers. When these two bodies joined forces in 1902 trade-unionism in general and syndicalism in particular received an immense accession of strength, and the doctrine subsequently remained—in spite of the efforts of political socialists to capture the *syndicats* for their own purposes—the characteristic expression of French revolutionary idealism.

Syndicalist doctrine has had considerable influence outside France. In the United States a movement of somewhat similar character arose with the organization of the Industrial Workers of the World (*q.v.*).

The influence of these ideas on the trade-union movement in Great Britain and Ireland has been very pronounced, though they have taken a different direction, modified by the traditional conservative instinct of the British working-class. In Great Britain the real cause of the permeation of certain unions by syndicalist ideas was the absorption of trade-union leaders in administration or in politics, which caused them to lose touch with the rank and file. Especially is this the case with regard to the miners, the railwaymen's unions and the engineers.

Daniel De Leon was a leader of the Socialist Labour Party in the United States from 1880 onwards, and his writings influenced British socialist thought, particularly in the Clyde and in the mining valleys of South Wales. Though not a syndicalist in the strict sense, he advocated organization by industry and the general strike. It is significant that 1903 saw in England the secession of the Socialist Labour Party from the Social Democratic Federation. After that date, in addition to the growing educational influence of the Independent Labour Party (though this was never syndicalist), was seen the promotion of the Workers' Socialist Federation, the British Socialist Party (in the post-war period) and the Communist League, all of which advocated practically the same structure of organization and policy. They all agreed in a lack of faith in political action, though not always refusing to utilize it, but their real *politik* was industrial action. After the Russian Revolution of 1917 they secured greater prominence; they became the stormy petrels of the labour world in Great Britain, and their effect on the political action of the Labour Party was seen in the Council of Action in August 1920.

In England, between 1900 and 1910, there was a growing dissatisfaction among the rank and file with political action. Despite the fact that the influence of the Labour Party in the House of Commons secured to a greater degree than ever before the trade-union movement freedom of industrial and political action by the Trades Disputes Act of 1906 and the Trade Union Act of 1913, it was felt by the far-sighted among the rank and file that a speeding-up was necessary, and State collectivism as a way out towards industrial democracy was discredited. James Connolly, the Irish Labour leader who was executed after the Easter rising in Ireland in 1916, started a similar organization to that of Daniel De Leon on the Clyde in 1905. In his pamphlet *Socialism made Easy*, he enunciated the syndicalist principles "that they who rule industrially will rule politically," and that "the functions of Industrial Unionism is to build up an industrial republic inside the shell of the political state, in order that when the industrial republic is fully organized it may crack the shell of the political state and step into its place in the scheme of the universe." Tom Mann, while in France and Australia, to which had been imported ideas of the I.W.W. from America, was powerfully influenced by the same theories, while on the Rand, in South Africa, a small but very influential group of leaders was working out the structure, forms and policy of a movement similar in character. In 1910 Tom Mann preached the new faith in all the big industrial centres and rapidly won many followers. Then followed the railway strike of 1911 and the great coal strike of 1912. It is quite clear that the National Union of Railwaymen and the Miners' Federation of Great Britain became organized as two of the most powerful unions in consequence of the new thought, *not* because their leaders had adopted syndicalism in the form taught by De Leon and the French group of thinkers, but because they adapted

it in the peculiar British way; they made it practical and definite; they shaped it in alliance with the political and trade-union structure of Britain. They disagreed with the syndicalist view of the State, but they recognized the driving power of the theories that stated "that political power is a reflex of industrial power." The transport workers soon had a similar federation, and after the strikes of 1911 and 1912 and the Irish transport workers' strike of 1913, the Triple Alliance (of railwaymen, transport workers and miners) was formed in 1915.

The alliance was brought to a test in 1921 by the coal dispute. The other sections of the Triple Alliance, the leaders of the railwaymen and transport workers, withdrew from their agreement to take part in the general strike called for on April 15, 1921, because the miners had refused to consider temporary district settlements. On April 1, 1921, over one million miners were "locked out" for refusing to accept drastic reductions in wages Again, so far from accepting any syndicalist notions of power, it is clear that the miners fought then, not for any change in the economic system of capitalism, but for the preservation of a tolerable standard of living Exactly the same position arose again on May 3, 1926, when the general strike actually took place, not because of any revolutionary object of overthrowing the State, but in defence of the miners' standard of life

The Trade Disputes and Trade Unions Act of June 1927 brought out clearly the two points of view: the trade-union view that sympathetic strikes even on a national scale need not necessarily be syndicalist in aim, but a legitimate weapon in defence of their standard of life; and the opposite view that whenever a strike inflicts "hardship upon the community," whatever that may mean, it may be declared illegal if it can be adjudged to be political in its object.

The classic controversy between the reformist and the revolutionary conception of working-class action has again been demonstrated by the emergence of Communist propaganda among the trade unions. The "National Minority Movement," after its first conference on Aug 25, 1924, sent a manifesto to the Trade Union congress in which occurs the following "For the first time in the history of the congress a definite and organized opposition within the unions faces the existing leadership and raises unreservedly the banner of revolutionary working-class politics in British trade unionism "

The promoters of the movement sought to show that it was the successor of the forces at work in trade unionism to bring about more efficiency, such as the shop stewards' movement, the amalgamation movement and the workshop committees' movement The trade unions are convinced that this minority movement is disruptive, that its purpose is to set the rank and file of the working class movement in bitter opposition to its elected and responsible representatives, that it has no affinity with syndicalism or the prewar revolutionary trade union of the Continental type, that in short it simply represents Communist activity and propaganda within the unions Its power for mischief is deemed to be great, and, although unimportant in numbers and of little influence, because of this steps have been taken to deal with it.

SYNDICATE. Originally the name of a council of syndics (*q.v.*), the word syndicate has in modern times come to be used to describe a body of men associated for commercial or financial purposes, especially when the body is temporary and *ad hoc.* The word has also been used to describe the combined use of news or articles by newspaper proprietors, as when an arrangement is made to circulate an article throughout a series of newspapers, when it is termed a "syndicated article."

In the Italian fascist economic structure, the local trade associations are termed syndicates, and all workers have to subscribe to them, whether they become members or not. These syndicates are juridical bodies and integral parts of the new Italian constitution. (*See* FASCISM, ECONOMICS OF.) (L. C. M.)

Press Syndicates are editorial organizations based on the modern business concept of large sales, wide distribution, relatively small cost to each purchaser but large aggregate cost and profits They supply to numerous newspapers fiction, cartoons, illustrated articles in single or series form often signed by well-known names. They exist partly by virtue of the fact that they are able to supply to any one newspaper material which that newspaper could not afford to collect for itself, and partly because some of the cleverest journalists are engaged in the business. Press syndicates are highly developed in the United States, where they supply more than 80% of the reading matter, and in Great Britain, where individuality still counts in the newspaper world, this method of mass production and dissemination of news is making headway

Major O J Smith is the inventor (1882) of the syndicate which first expressed itself by means of the distribution of stereotyped plates manufactured at central points and served to newspapers in the form of metal castings. In connection with this enterprise the American Press Ass'n which at one time served as many as 12,000 newspapers, also sent out material in manuscript proof and electrotype shell form, and made hundreds of small country newspapers possible The distribution by stereotype matrices, to-day so important, came later The prosperity of press syndicates since 1900 is instanced by the special foreign service of the *Chicago Daily News*, and the local and general services of the United Press (1907), the Associated Press (1900), the International News Service and others

Two well known syndicate pioneers were S. S McClure and Edward Marshall. McClure introduced Robert Louis Stevenson and Rudyard Kipling to American readers (W. S. HI.)

SYNEDRIUM, a Rabbinic or legal body in Jerusalem, the Sanhedrin. the form *Sanhedrim* is based on false etymology, suggesting a Hebrew masc plural ending *-im* added to a nonexistent noun *Sanhēder.* The *Oxford English Dictionary* (cited in H W. Fowler's *Mod Eng Usage*, 1926, p 512) makes the following erroneous statement. "the incorrect form *Sanhedrin* . . . has always been in England (from the 17th cent) the only form in popular use " As no Hebrew noun ending in M occurs, the only correct equivalent to סנהדרין must be *Sanhedrin* The existence of a court at Jerusalem is indicated in II Chron xix, 8. An aristocratic Council of Elders and priests is mentioned both before and during the Maccabaean age (*e g.*, Josephus, *Ant*, xii, 3, 3). Probably the High Priest presided from early times.

The accounts in the Mishnah do not entirely agree with those of Josephus and with New Testament references but the amount of divergence is a matter of dispute. There are two lines of thought among modern scholars, some supporting the Mishnah, others maintaining that its information is an "academic reconstruction," hence unhistorical. That the Jewish court early lost its power is generally admitted (*cf.* John xviii., 31). Forty years before the fall of the Temple it could no longer inflict capital punishment (Jer. Sanh 18a) and the right of deciding financial cases had been abrogated during the reign of Alexander Jannaeus (*cf*, T. B. Sanh. 41a). Nevertheless legal tradition was well preserved and the evidence of authorities such as Jose b. Ḥalafta cannot easily be brushed aside. Büchler (*cit. infr.*) reconciles the conflicting evidence by assuming that there were two bodies, one, that of Josephus and the Gospels, possessing civil authority and one, that of the *Mishnah,* with purely religious functions, *e.g.*, the fixing of the calendar or the purity of priests. The former sat in the town or on the west edge of the Temple hill; the latter, called "the great Sanh.," sat in the Xystus or

Lishkath hag-Gāzith (chamber of hewn stone) and was composed of 71 members, mostly Pharisees, over whom the *Nasi'* and *Ab Beth Din* (Rabbis) presided. The lesser Sanhedrin of 23 members, mostly Sadducees and priests, was under the leadership of the High Priest.

SYNESIUS (*c.* 373–*c.* 414), bishop of Ptolemais in the Libyan Pentapolis after 410, was born of wealthy parents, who claimed descent from Spartan kings, at Cyrene between 370 and 375. While still a youth (393) he went with his brother Euoptius to Alexandria, where he became an enthusiastic Neoplatonist and disciple of Hypatia (*q.v.*). On returning to his native place about the year 397 he was chosen to head an embassy from the cities of the Pentapolis to the imperial court to ask for remission of taxation and other relief.

After Aurelian had granted the petition of the embassy, Synesius returned to Cyrene in 400, and spent the next ten years partly in that city, when unavoidable business called him there, but chiefly on an estate in the interior of the province, where in his own words "books and the chase" made up his life. His marriage took place at Alexandria in 403; in the previous year he had visited Athens. In 409 or 410 Synesius, whose Christianity had until then been by no means very pronounced, was popularly chosen to be bishop of Ptolemais, and, after long hesitation on personal and doctrinal grounds, he ultimately accepted the office thus thrust upon him, being consecrated by Theophilus at Alexandria. One personal difficulty was obviated by his being allowed to retain his wife, to whom he was much attached; but as regarded orthodoxy he expressly stipulated for personal freedom to dissent on the questions of the soul's creation, a literal resurrection, and the final destruction of the world, while at the same time he agreed to make some concession to popular views in his public teaching (*τὰ μὲν οἴκοι φιλοσοφῶν, τὰ δ' ἔξω φιλομυθῶν*). His tenure of the bishopric was troubled by domestic bereavements and by barbarian invasions of the country (in repelling which he proved himself a capable military organizer) and by conflicts with the prefect Andronicus, whom he excommunicated for interfering with the Church's right of asylum. The date of his death is unknown; it is usually given as *c.* 414.

His extant works are—(1) a speech before Arcadius, *De regno;* (2) *Dio, sive de suo ipsius instituto*, in which he signifies his purpose to devote himself to true philosophy; (3) *Encomium calvitii* (he was himself bald), a literary *jeu d'esprit*, suggested by Dio Chrysostom's *Praise of Hair;* (4) *De providentia*, in two books; (5) *De insomniis;* (6) 157 *Epistolae;* (7) 12 *Hymni*, of a contemplative, Neoplatonic character; and several homilies and occasional speeches. The *editio princeps* is that of Turnebus (Paris, 1553); it was followed by that of Morell, with Latin translation by Petavius (1612; greatly enlarged and improved, 1633; reprinted, inaccurately, by Migne, 1859).

SYNGE, JOHN MILLINGTON (1871–1909), Irish dramatist, was born at Rathfarnham near Dublin April 16, 1871. Educated at Trinity college, Dublin, he travelled for some years on the Continent, spending much of his time in Paris. He returned in 1898 to the Aran Isles. Here he wrote a number of sketches dealing with the life of the islanders, which were later collected in *The Aran Islands* (1907). In these and other sketches of the same period he had not quite shaken off the obsession of stylism, and still had a wish "to do for the west of Ireland what Pierre Loti had done for the Bretons." Gradually, however, Ireland took hold of him, and, turning to the dramatization of incidents in the life he now knew intimately, he began to elaborate, partly from his notebooks and partly from the writings of Lady Gregory and Douglas Hyde, that richly imaginative Anglo-Irish dialect which he used with such complete success. When, in 1904, he became a director of the newly opened Abbey Theatre, Dublin, he had already produced two one-act plays, *The Shadow of the Glen* (1903) and *Riders to the Sea* (1904), published in one volume (1905). *The Well of the Saints,* a beautiful three-act play produced in 1905, was regarded by some as an affront to Irish morals, and when *The Playboy of the Western World* appeared in Jan. 1907, it was interrupted every night for a week by an organised disturbance. When the real merits of the play became known, it contributed largely to the fame of the Abbey Theatre. Time has shown how deeply Synge penetrated into the soul of the Irish peasant. The richness of the dialogue and the suggestion which it conveys of a permanent human enigma combine to make it a masterpiece. Synge's latest volumes were a collection of his poetical works entitled *Poems and Translations* (1909), and another play, *Deirdre of the Sorrows* (1910) which he all but completed before his death. Synge's greatest work is probably *The Playboy*, though some critics give pride of place to *Deirdre.* Synge died in Dublin March 24, 1909.

SYNOPTIC GOSPELS and **SYNOPTIC PROBLEM.** The first three Gospels, Matthew, Mark, Luke, are known as the Synoptic Gospels because, in matter, language, and order, they have much in common, and can, therefore, be viewed together or synoptically. The Synoptic Problem is the problem of the relations between these Gospels, whether of influence, interdependence, or common origin, arising from their common features. (*See* GOSPEL, BIBLE: NEW TESTAMENT, section *Modern Criticism*, and the articles on the several Gospels.)

SYNTHETIC RUBBER: *see* RUBBER IN INDUSTRY.

SYPHAX, king of the Massaesyli, a tribe of western Numidians, played an important part in the later stages of the Second Punic War. In 213 a quarrel was in progress between him and Carthage; the Scipios leaped at this chance of establishing an ally in Africa, and sent a military mission to Syphax.

SYRA or **SYROS** (anc. Σύρος, perhaps Homeric Συρίη), a Greek island in the middle of the Cyclades (length about 10 m., breadth 5, area 42½ sq.m.). The prehistoric importance of the island is attested by early Aegean antiquities. In ancient times it was remarkably fertile, but the destruction of its forests has led to loss of alluvial soil, and left it a brown and barren rock, with scanty aromatic scrub, pastured by sheep and goats. In the 19th century Syra became the commercial centre of the Archipelago, and is also the residence of the nomarch of the Cyclades and the seat of the central law courts. The population rose to about 33,700, but is said to have declined though Hermoupolis has 21,156 inhabitants (1928). It suffers from the competition of Piraeus, and latterly of Salonika. Syra is also a province of the department of the Cyclades.

Hermopolis (better Hermoupolis), the chief town, is built in a bay of the east coast. Old Syra, on a conical hill behind the port town, was built by the Capuchins, who in the middle ages chose Syra as the headquarters of a mission. On the outbreak of the war of Greek independence about 40,000 refugees from Chios, after being scattered throughout Tenos, Spezia, Hydra, etc., and rejected by Ceos, rallied at Syra under the protection of the French flag till the freedom of Greece was achieved. The harbour, with a breakwater 273 yd. long, has a depth of 25 ft. diminishing to 12 ft.

SYRACUSE, a city of Sicily (Gr. Συράκουσαι; Lat. *Syracusae,* Ital. *Siracusa*), the capital of a province of the same name, situated on the east coast of the island, 54m. by rail S. by E. of Catania, and about 32m. direct. Pop. (1881), 21,739; (1906), 23,250 (town), 35,000 (commune); (1921), 45,946 (town), 49,662 (commune).

Syracuse was the chief Greek city of ancient Sicily, and one

of the earliest Greek settlements in the island. It was founded from Corinth, and Thucydides, who gives the date as the year after the foundation of Naxos (*i.e.*, 734 B.C.), mentions that the leader Archias expelled the Sicel inhabitants from Ortygia. (*See* under SICILY.) Their presence there was definitely proved by the discovery of traces of huts and of a rock-cut tomb of the beginning of the second Sicel period on Ortygia, while similar tombs may be seen both on the north and south edges of the terrace of Epipolae, and on the peninsula of Plemmyrium. (For this and other prehistoric sites in the neighbourhood of Syracuse *see* SICILY, *Pre-Hellenic Archaeology*.)

Till the beginning of the 5th century B.C. our notices of Syracuse history are fragmentary, and we do not even know when the mole connecting the island with the mainland was constructed. In its external development Syracuse differed somewhat from other Sicilian cities. Although it lagged in early times behind both Gela and Acragas (Agrigentum), it very soon began to aim at a combination of land and sea power. In 663 it founded the settlement of Acrae, in 643 Casmenae, and in 598 Camarina, of which the first was unusually far inland. The three together secured for Syracuse a continuous dominion to the south-east coast. They were not strictly colonies but outposts; Camarina indeed was destroyed after a revolt against the ruling city.

Gelon and Hieron.—Hippocrates, tyrant of Gela (492–485), threatened the independence of Syracuse as well as of other cities, and it was saved only by the joint intervention of Corinth and Corcyra and by the cession of the vacant territory of Camarina. In 485 the *Gamoroi*, or landowners (*i.e.*, the descendants of the original settlers, who formed an aristocratic body), who had been expelled by the Demos and the Sicel serfs and had taken refuge at Casmenae, craved help of Gelon, the successor of Hippocrates, who took possession of Syracuse, without opposition, and made it the seat of his power. He gave citizenship both to mercenaries and to settlers from Greece and added to the population the inhabitants of other cities conquered by him, so that Syracuse became a city of mixed population in which the new citizens had the advantage. He then extended the city by including within the fortifications the low ground (or at any rate the western portion of the low ground) between Upper Achradina and the island and making the agora there; at the same time (probably) he was able to shift the position of the crossing to the island by making a new isthmus in the position of the present one, the old mole being broken through so as to afford an outlet from the Little Harbour on the east. The island thus became the inner city, the stronghold of the ruler. Gelon's general rule was mild, and he won fame as the champion of Hellas by his great victory over the Carthaginians at Himera. He is said to have been greeted as king; but he does not seem to have taken the title in any formal way.

Gelon's brother and successor, Hieron (*q.v.*) (478–467), kept up the power of the city and won himself a name by his encouragement of poets, especially Aeschylus and Simonides, and philosophers; while his Pythian and Olympian victories made him the special subject of the songs of Pindar and Bacchylides. But in his internal government he was suspicious, greedy and cruel. After family disputes the power passed to his brother Thrasybulus, who was driven out next year by a general rising. Syracuse thus became a democratic commonwealth. Renewed freedom was celebrated by a colossal statue of Zeus Eleutherius and by a yearly feast in his honour. But when the mercenaries and other new settlers were shut out from office new struggles arose. The mercenaries, as in the last rising, held Ortygia and Achradina. The people now walled in the suburb of Tyche to the west of Achradina. The mercenaries were at last got rid of in 461. Although we hear of attempts to seize the tyranny and of an institution called *petalism*, like the Athenian ostracism, designed to guard against such dangers, popular government was not seriously threatened for more than 50 years. The part of Syracuse in general Sicilian affairs has been traced in the article SICILY (*q.v.*). We hear of a naval expedition to the Etruscan coast and Corsica about 453 B.C. and of the great military and naval preparations of Syracuse in 439.

The Athenian Siege.—The Athenian siege (415–413) is of the deepest importance for the topography of Syracuse. (The chief authorities for the siege are Thucydides [bks. vi. and vii.], Diodorus [bk. xiii.] and Plutarch, *Nicias*.) Through the whole siege there was a treasonable party within the city, which kept up a correspondence with the besiegers. When the Athenian fleet under Nicias, Alcibiades and Lamachus was at Rhegium in Italy, Athens had the prize within her grasp, and she lost it wholly through the persistent dilatoriness and blundering of Nicias (*q.v.*). It was at his advice that the summer and autumn of 415 were frittered away, and the siege not begun till the spring of 414. By that time the Syracusans had built a wall from north to south across Epipolae, taking in Tyche and Temenites, so as to screen them from attack on the side of Epipolae on the north-west. They did not, however, occupy Euryelus, at the western extremity of the high ground of Epipolae, and this omission allowed the Athenians to obtain possession of the whole plateau and to begin the investment of the city. The Syracusans then carried a counterwork up the slope of Epipolae, which, if completed, would cut in two the Athenian lines and frustrate the blockade. At this point Nicias showed considerable military skill. The Syracusans' work was destroyed by a prompt and well-executed attack; and a second counterwork carried across marshy ground some distance to the south of Epipolae and near to the Great Harbour was also demolished after a sharp action, in which Lamachus fell, an irretrievable loss. However, the blockade on the land side was now almost complete, and the Athenian fleet had at the same time entered the Great Harbour. The citizens began to think of surrender, and Nicias was so confident that he neglected to push his advantages. He left a gap to the north of the circular fort which formed the centre of the Athenian lines, the point where Epipolae slopes down to the sea, and he omitted to occupy Euryelus. He made a final and irretrievable blunder in letting the Spartan Gylippus first land in Sicily and then march at the head of a small army, across the island, and enter Syracuse by way of Epipolae, past Euryelus. Just before his arrival a few ships from Corinth had made their way into the harbour with the news that a great fleet was already on its way to the relief of the city. The tables were now completely turned. The military skill of Gylippus enabled the Syracusan militia to meet the Athenian troops on equal terms, to wrest from them their fortified position on Plemmyrium, which Nicias had occupied as a naval station shortly after Gylippus's arrival, and thus to drive them to keep their ships on the low beach between their double walls, to take Labdalum, an Athenian fort on the northern edge of Epipolae, and make a third counterwork right along Epipolae in a westerly direction, to the north of the circular fort. The Athenians were thus reduced to such a plight that, as Nicias said in his despatch towards the close of 414, they were themselves besieged rather than besieging. The naval preparations of the Syracusans, under the advice of Hermocrates, had led them, too, to confidence in their powers of giving battle to the Athenian fleet. In the first sea-fight, which took place simultaneously with the capture of Plemmyrium, they had been unsuccessful; but in the spring of 413 they actually won a victory over the Athenians in their own element.

On the very next day, however, a second Athenian fleet arrived under Demosthenes and Eurymedon, with 73 ships of war and a large force of heavy infantry and light troops. Demosthenes decided at once to make a grand attack on Epipolae, with a view to recovering the Athenian blockading lines and driving the Syracusans back within the city walls. The assault was made by night by way of Euryelus under the uncertain light of the moon, and this circumstance turned what was very nearly a successful surprise into a ruinous defeat. The army was now thoroughly out of heart and Demosthenes was for at once breaking up the camp, embarking the troops, and sailing back to Athens. But Nicias could not bring himself to face the Athenian people at home, nor could he be prevailed on to retire promptly to some position on the coast, such as Catania or Thapsus. He dallied till the end of August, many weeks after the defeat, when the coming of Syracusan reinforcements decided him to depart; but

on Aug. 27 was an eclipse of the moon, on the strength of which he insisted on a delay of almost another month. The Syracusans now blocked the mouth of the Great Harbour, and the Athenian fleet, after a frantic effort to break out and a desperate conflict, was utterly defeated and half destroyed. The broken and demoralized army, its ranks thinned by fever and sickness, at last began its hopeless retreat, attempting to reach Catania by a circuitous route; but, harassed by the numerous Syracusan cavalry and darters, after a few days of dreadful suffering it was forced to lay down its arms. The Syracusans sullied the glory of their triumph by putting Nicias and Demosthenes to death.

Dionysius I.—Her great deliverance and victory naturally stirred up the energies of Syracuse at home and abroad. Syracusan and Selinuntine ships under Hermocrates now play a distinguished part in the warfare between Sparta and Athens on the coast of Asia. Under the influence of Diocles the constitution became a still more confirmed democracy, some at least of the magistracies being filled by lot. Diocles appears also as the author of a code of laws of great strictness. Under these influences Hermocrates was banished in 409. In 407 he was slain in an attempt to enter the city, and with him was wounded Dionysius, son of another Hermocrates and an adherent of the aristocratic party, but soon afterwards a demagogue, though supported by some men of rank, among them the historian Philistus. By accusing the generals engaged at Acragas in the war against Carthage, by obtaining the restoration of exiles, by high-handed proceedings at Gela, he secured his own election as sole general with special powers. He next procured from a military assembly at Leontini a vote of a bodyguard; he hired mercenaries and in 406–405 came back to Syracuse as tyrant of the city. Dionysius kept his power till his death 38 years later (367). But it was well-nigh overthrown before he had fully grasped it. After his defeat before Gela (*see* SICILY) his enemies in the army reached Syracuse before him, plundered his house, and horribly maltreated his wife. He came and took his vengeance, slaying and driving out his enemies, who established themselves at Aetna. In 397 Syracuse had to stand a siege from the Carthaginians under Himilco, who took up his quarters at the Olympieum, but his troops in the marshes below suffered from pestilence, and a masterly combined attack by land and sea by Dionysius ended in his utter defeat. Dionysius, however, allowed him to depart without further pressing his advantage. This revolution and the peace with the Carthaginians confirmed Dionysius in the possession of Syracuse, and left it the one great Hellenic city of Sicily, which, however enslaved at home, was at least independent of the barbarian. Dionysius was able, like Gelon, though with less success and less honour, to take up the rôle of the champion of Hellas.

During the long tyranny of Dionysius the city grew greatly in size, population and grandeur. Syracuse absorbed the population of Gela, Camarina and Acragas, and received large accessions from some of the Greek cities of southern Italy, from Hipponium on its west and Caulonia on its east coast, both of which Dionysius captured in 389 B.C. There had also been an influx of free citizens from Rhegium. Dionysius largely extended the fortifications of Syracuse. The island (Ortygia) had been provided with its own defences, converted, in fact, into a separate stronghold. Dionysius, to make himself perfectly safe, drove out a number of the old inhabitants and turned the place into a barracks, he himself living in the citadel. Profiting by the experience gained during the Athenian siege, he included in his new lines the whole plateau of Epipolae, with a strong fortress at Euryelus, its apex on the west; the length of the outer lines (excluding the fortifications of the island) is about 12m. Syracuse was now the most splendid and the best fortified of all Greek cities. Its naval power, too, was vastly increased; the docks were enlarged, and 200 new warships were built. The fleet of Dionysius was the most powerful in the Mediterranean. It was doubtless fear and hatred of Carthage, from which city the Greeks of Sicily had suffered so much, that urged the Syracusans to acquiesce in the enormous expenditure which they must have incurred under the rule of Dionysius. Much, too, was done for the beauty of the city as well as for its strength and defence. Several new temples were built, and gymnasia erected outside the walls.

Dionysius' Successors.—Under his son, the younger Dionysius—an easy, good-natured, unpractical man—a reaction set in amongst the restless citizens of Syracuse. His uncle, Dion, was for a time the trusted political adviser of his nephew Dionysius II. Dion's idea seems to have been to make Dionysius something like a constitutional sovereign, and with this view he brought him into contact with Plato. But Dionysius had Philistus and others about him, who were opposed to any kind of liberal reform, and the result was the banishment of Dion from Syracuse as a dangerous innovator. Ten years afterwards, in 357, the exile entered Achradina a victor. A siege and blockade followed, till Dion made himself finally master of the mainland city. Ortygia, provisions failing, was also soon surrendered. Dion's rule lasted only three years, for he perished in 354 by the hand of an assassin.

Of what took place in Syracuse during the next ten years we know but little. The younger Dionysius came back and from his island fortress again oppressed the citizens. Sicily, too, was again menaced by Carthage. Syracuse, in its extremity, asked help from the mother-city, Corinth; and Timoleon (*q.v.*) delivered Syracuse from the younger Dionysius and from Hicetas, who held the rest of Syracuse, and won a decisive triumph over Carthage and the safe possession of Sicily west of the river Halycus, the largest portion of the island. From 343 to 337 he was supreme at Syracuse, with the hearty good will of the citizens. Syracuse, with an influx of a multitude of new colonists from Greece and from towns of Sicily and Italy, once more became a prosperous city. Timoleon, having accomplished his work, accepted the position of a private citizen. After his death (337) a splendid monument, with porticoes and gymnasia surrounding it, known as the Timoleonteum, was raised to his honour.

In the interval of 20 years between the death of Timoleon and the rise of Agathocles (*q.v.*) to power another revolution at Syracuse transferred the government to an oligarchy of 600 leading citizens. It was shortly after this revolution, in 317, that Agathocles, with a body of mercenaries from Campania and a host of exiles from the Greek cities, backed up by the Carthaginian Hamilcar, became tyrant of the city, and the senate and the heads of the oligarchical party were massacred wholesale, while a unanimous vote of the people gave him absolute control over the fortunes of Syracuse. His wars in Sicily and Africa left him time to do something for the relief of the poorer citizens at the expense of the rich, as well as to erect new fortifications and public buildings; and under his strong government Syracuse seems to have been at least quiet and orderly. After his death in 289 comes another period of revolution and despotism; and but for the brief intervention of Pyrrhus in 278 Syracuse, and indeed all Sicily, would have fallen a prey to the Carthaginians.

A better time began under Hieron II., who had fought under Pyrrhus and who rose from the rank of general of the Syracusan army to be tyrant—king, as he came to be soon styled—about 270. During his reign of more than 50 years (*see* HIERON) Syracuse enjoyed tranquillity, and seems to have grown greatly in wealth and population. Hieron's rule was kindly and enlightened, combining good order with a fair share of liberty and self-government. His financial legislation was careful and considerate; his laws as to the customs and the corn tithes were accepted and maintained under the Roman government, and one of the many bad acts of Verres was to set them aside. It was a time, too, for great public works—works for defence at the entrance of the Lesser Harbour between the island and Achradina, and temples and gymnasia. Hieron through his long reign was the stanch friend and ally of Rome in her struggles with Carthage.

Capture by the Romans.—Hieronymus, the grandson of Hieron, thought fit to ally himself with Carthage, but he soon fell in a conspiracy. There was a fierce popular outbreak and more bloodshed; the conspirators were put to death and Hieron's family was murdered; whilst the Carthaginian faction, under the pretence of delivering the city from its tyrants, got the upper hand and drew the citizens into open defiance of Rome. M. Claudius Marcellus was then in command of the Roman army in Sicily, and he threatened the Syracusans with attack unless

they would get rid of Epicydes and Hippocrates, the heads of the anti-Roman faction. Marcellus struck his first blow at Leontini, which was quickly stormed; and its sack roused the feeling of the Syracusans against any negotiations with the Roman general, and, putting themselves under Epicydes and Hippocrates, they closed their gates on him. Marcellus, after an unsuccessful attempt to negotiate, began the siege in regular form (214 B.C.) by both land and sea, establishing a camp on Polichne, where stood the old temple of Olympian Zeus; but he made his chief assault on the northern side and on the defences of Tyche. The city was defended by a numerous soldiery and by the ingenious contrivances of Archimedes, whose engines dealt havoc among the Roman ships and frustrated the attack on the fortifications on the northern slopes of Epipolae. Marcellus had recourse to a blockade, and at last, in 212, information was given him that the Syracusans were celebrating a great festival to Artemis. Making use of this opportunity, he forced the *Hexapylon* entrance by night and established himself in Tyche and on the heights of Epipolae The strong fortress of Euryelus held out for a time, but, being now isolated, it soon had to surrender. The "outer" and the "inner" city of Thucydides still held out, whilst a Carthaginian fleet was moored off Achradina and Carthaginian troops were encamped on the spot. But a pestilence broke out in the autumn of 212, which swept them clean away and thinned the Roman ranks. The ships sailed away to Carthage; on their way back to Syracuse with supplies they could not get beyond Cape Pachynus owing to adverse winds, and they were confronted by a Roman fleet. All hope for the city being now at an end, the Syracusans threw themselves on the mercy of Marcellus; but Achradina and the island still held out for a brief space under the Syracusan mercenaries, till one of their officers, a Spaniard, betrayed the latter position to the enemy, and at the same time Achradina was carried and taken. Marcellus gave the city up to plunder, and the art treasures in which it was so rich—many of the choicest of them, no doubt—were conveyed to Rome. Archimedes perished in the confusion of the sack while he pursued his studies.

Syracuse was now simply one of the provincial cities of Rome's empire. It retained much of its Greek character and many of its finest public buildings. Its importance and historic associations naturally marked it out as the residence of the Roman praetor or governor of Sicily. Cicero often speaks of it as a particularly splendid and beautiful city, as still in his own day the seat of art and culture. Caligula restored its decayed walls and some of its famous temples. It was plundered by Frankish pirates about A.D 286. In the 4th century it is named by the poet Ausonius, chiefly, perhaps, on the strength of its historic memories; and there was a purple factory here under an imperial procurator. In 665 Heraclius Constans fixed his capital here, but owing to his oppressive government was assassinated in 668. Syracuse has been a place of comparatively little importance since the year 878, when it was destroyed by the Saracens.

Archaeology.—The mediaeval and modern town of Syracuse (with the exception of a new quarter which has sprung up since the construction of the railway between the station and the island) is confined to the island. This contains the remains of two Doric temples. The older, belonging probably to the beginning of the 6th century B.C., appears, from an inscription on the uppermost step, to have been dedicated to Apollo. It was a peripteral hexastyle of 42 columns; the portion excavated shows that its total width is 74½ft., the width of the cella 38½ft., the lower diameter of the columns 6¼ft. The other temple, into which the cathedral was built in A.D. 640, is to be dated 474–460 B.C. It was a peripteral hexastyle of 36 columns, with a total length of 180ft. and a total breadth of 72ft; the columns have a lower diameter of 5¾ft., and the intercolumniation is 13½ft. It is almost certainly the temple of Athena. The site was previously occupied by buildings of the 7th and 6th centuries B.C, including an archaic temple and a great sacrificial altar, which were destroyed to make room for it. Their terra-cotta decorations were, however, carefully buried under the pavement of the space which surrounded it; and they are of the highest importance in the history of design, showing that even if the method was Corinthian in origin it was in Sicily that it reached its highest development.

Near the west coast of the island is the famous fountain of Arethusa. According to the legend, the nymph Arethusa was changed into the fountain by Artemis to deliver her from the pursuit of the river-god Alpheus (*q.v.*); and the spring, which was fresh until an earthquake broke the barrier and let in the salt water, was supposed to be actually connected with the river. There are interesting remains of mediaeval architecture in the closely built town with its narrow streets; the beautiful 14th-century windows of the Palazzo Montalto may be especially noticed, and also the 13th-century Castello Maniace at the southern extremity of the island. The town also contains the large and well arranged archaeological museum which is the creation of Prof. Orsi, and is of the highest importance for both pre-Hellenic and Hellenic archaeology. The discoveries of recent years in the south-eastern portion of Sicily, including especially the objects found in Sicel and Greek cemeteries, may be studied there. The isthmus connecting the island with the mainland, which was defended by strong fortifications erected by Charles V. and Philip II. (now demolished), does not occupy the site of the mole erected in the 6th or 7th century B C, running due north from the north point of the island. On the landward side of the new isthmus was the agora, in which remains of a colonnade of the Roman period have been found. To the west are the remains of an extensive building of the Roman period, probably a palaestra with a small Odeum attached To the west-north-west is an extensive necropolis, mostly of the 7th and 6th centuries B.C. (For the cemeteries see *The Year's Work in Classical Studies*, p. 123 [1924–25].) This necropolis was included within the defensive wall of Dionysius, a portion of which, no less than 18½ft. thick, was found running diagonally across the new cemetery, and later an outwork in front of it was discovered. East of this point it probably followed the edge of the low terrace above the marsh (the ancient Lysimeleia), while in the other direction it ran north-north-west, making straight for the western edge of the gorge known as the Portella del Fusco, which was thus included within the fortifications, as it would otherwise have afforded a means of access to the enemy. Here the wall gained the top of the cliffs which mark the southern edge of the plateau of Epipolae, which from this point onwards it followed as far as Euryelus. The south wall of Epipolae, considerable remains of which exist, shows traces of different periods in its construction, and was probably often restored. It is built of rectangular blocks of limestone generally quarried on the spot. Euryelus, the point where the terrace of Epipolae narrows down to a ridge about 60yds. wide, which is its only link with the hills to the west, had thrice proved during the Athenian siege to be the key to Syracuse It now bears the ruins of a mighty fortress, finer than that which defends the entrance to the acropolis of Selinus—the most imposing, indeed, that has come down to us from the Greek period—which there is no doubt is the work of Dionysius. The total length of the works is about 440yds. In front of the castle proper are three ditches, the innermost of which can be reached from the interior of the castle by a complicated system of underground passages. The front of the castle is formed by five massive towers; behind it are two walled courtyards, to the north of the easternmost of which is the well-guarded main entrance to the plateau of Epipolae (narrower minor entrances are to be seen on both the north and the south sides) communicating by a long underground passage with the inner ditch in front of the castle proper. On the north side of Epipolae the cliffs are somewhat more abrupt; here the wall, of a similar construction to that on the south, is also traceable, but here it is apparently all of one period. It is, indeed, recorded by Diodorus that Dionysius built the north wall from Euryelus to the *Hexapylon* in 20 days for a length of 2¾m., employing 60,000 peasants and 6,000 yoke of oxen for the transport of the blocks.

The most important buildings of which we have any remains are to be found in the lower part of Achradina and in Neapolis, a quarter of which we hear first in the time of Dionysius, and which at first was confined to the lower ground below Temenites; but in Roman times included it and the theatre also, though it

did not extend beyond the theatre to the uppermost part of the plateau. In lower Achradina remains of Roman private houses have been found, and it is in this district that the early Christians constructed their catacombs. (St. Paul tarried at Syracuse three days on his way to Rome [Acts xxviii. 12].) Those which are entered from near the 12th-century church of S. Giovanni, situated near an ancient temple, are extensive and important, and include the ancient crypt of S. Marcianus, and the type is different from that of the Roman catacombs, the galleries being far larger (partly owing to the hardness of the limestone in which they are excavated), and having circular chambers at the points of junction. In Neapolis, on the other hand, public buildings predominate. The temple of Apollo Temenites has entirely disappeared, but the theatre, entirely hewn in the rock, is still to be seen. It is the largest in Sicily, being 138½yds. in diameter, and having 59 rows of seats; the 11 lower tiers were originally covered with marble. Each of the nine *cunei* or divisions bore a name; the inscriptions of five of them, still preserved on the rock, are in honour of Zeus, Heracles, King Hieron II., his wife Philistis, and his daughter-in-law Nereis. It was restored after 238, after her marriage to Gelon. Of the stage nothing but cuttings in the rock and foundations are visible. (*See* G. E. Rizzo, *Il Teatro Greco di Siracusa* [1923] for a most careful study. *See* also THEATRE.) The situation is well chosen, commanding a splendid view over the Great Harbour, and it is often used for classical performances. Not far off to the south-east is the amphitheatre, probably erected by Augustus when he founded a colony at Syracuse; it is partly cut in the rock and partly built. It is inferior in size only to the Colosseum and the amphitheatres of Capua and Verona, measuring about 153 by 130yds. over all: the arena is 76 by 43yds. To the west of the amphitheatre is the foundation of the great altar erected by Hieron II., 217yds. long by 24 wide, and about 6yds. in height. To the north-west of the theatre a winding road ascends through the rock, with comparatively late tomb chambers on each side of it. In this district are seen hundreds of small niches cut in the rock, as a rule about 2ft. square and a few inches deep, which served for containing inscriptions or reliefs, sometimes of a sepulchral character, but sometimes relating to the cult of a divinity. Both the districts just described also contain huge quarries, the famous Lautumiae (from Gr. λᾶας, stone, and τεμεῖν, to cut; hence λατομία, quarry) of Syracuse, over 100ft. deep and of great extent (though through the collapse of the pillars supporting the undermined rock they have become still larger than they were in ancient times).

We have already seen that immediately outside Lower Neapolis on the south the marshes of Lysimeleia begin, which proved fatal to more than one besieging force. They are traversed by the Anapus, with its tributary the Cyane, the latter famous for the papyrus planted by the Arabs, which here alone in Europe grows wild in the stream. To the south of the Anapus is the hill of Polichne, on which stood the Olympieum, attributed on stylistic grounds to 581 B.C. Its monolithic columns, of which two are still standing, are about 21ft. in height and 6ft. in lower diameter: its length is estimated at 197ft., its breadth at 66¾ft. This and the temple of Apollo are the earliest known examples of peripteral temples in stone. The hill was frequently occupied in attacks on Syracuse by the besieging force. The hill of Dascon is to be sought a trifle to the south-east, to the south of the mouth of the Anapus, on the edge of the Great Harbour, at the Punta Caderini. From this point southwards the shore of the Great Harbour, previously low and marshy, begins to rise, until the rocky promontory of Plemmyrium is reached.

(E. A. F.; T. A.)

SYRACUSE, a city of New York, U.S.A., the county seat of Onondaga county; midway between Albany and Buffalo, at the south end of Lake Onondaga, on Federal highways 11 and 20 and the State Barge canal. It has a municipal airport and is served by the Lackawanna, the New York Central, the West Shore and six inter-urban electric railways and by 34 motor-truck lines. Pop. (1920) 171,717 (19% foreign-born white); 1928 estimate 199,300.

Syracuse has a beautiful site of 25·31 sq.m., on high ground, in an amphitheatre of hills around the south end of the lake (5 m. long), surrounded by a rich agricultural region, within a short drive of the Finger Lake region and less than 100 m. from the Adirondacks and the Thousand islands. Two creeks wind through the city to the lake. Wide boulevards have been constructed over the abandoned beds of the Erie canal (which crossed it from east to west) and the Oswego canal (which came in from the north-west and joined the Erie in the heart of the city). There are six large parks covering over 400 ac. and many small parks and playgrounds; 320 m. of streets (154 m. paved); 106 churches, 3,341 retail business houses, large modern hotels and beautiful residential streets, many of them arched with interlacing elms. Salina street is the main business thoroughfare. Around St. Mary's circle are grouped the county court-house, the public library, the Cathedral of the Immaculate Conception and the unique building of the First Baptist church, which houses a hotel, built around and above the church, in a beautiful structure of ecclesiastical architecture. Syracuse university (*q.v.*) occupies 100 ac. in the south-eastern part of the city, and on the western border are the State fair grounds (with extensive exhibition halls and a coliseum seating 7,500) where the State fair has been held annually since 1890. Six miles south is the Onondaga Indian reservation.

The city operates under a mayor-and-council form of government. The water-supply, brought from Skaneateles lake (20 m. S.W.) by a gravity system, is ample for a much larger population. Hydro-electric current is available from Niagara Falls and the Salmon river. The public educational system comprises 40 elementary, 5 junior high and 3 senior high schools, a normal, a night and a continuation school, and there are 17 parochial and several other private schools. The city's assessed valuation for 1927 was $302,326,444.

The Syracuse region, when first visited by Europeans, was the home of the Onondaga Nation and the capital of the Five (later Six) Nations of the Iroquois. It was visited by Champlain in 1615, by Radisson (while a captive of the Mohawks) in 1651, and in 1654 by Simon le Moyne, a Jesuit missionary, who found that the spring of which the Indians would not drink (because they believed a demon lived in it and gave the water an evil smell) was a fountain of salt brine. A mission was founded in 1655 by Chaumonot and Dablon near the present village of Liverpool (5 m. N.W. of Syracuse) and the next year the mission and a military post were formally established with pomp and ceremony. Both were abandoned because of the hostility of the Mohawks in 1658, but the mission was resumed in 1668 and continued through the century. The Onondaga village (south of the lake) was visited by many important representatives of the French and the English between 1670 and 1760 in their rivalry for the friendship of the Five Nations; and the raid from Ft. Schuyler (April 21, 1779) which determined the Onondagas to side with the British in the Revolution, took place within the present limits of Syracuse. The first white settler on the site of the city was Ephraim Webster, who established a trading post near the mouth of Onondaga creek in 1786. In 1788 Asa Danforth came from Mayfield (New York) with his wife and son. He built a saw-mill and a grist-mill, organized the militia, and is called "the father of Onondaga county." In 1788 the State undertook, by treaty with the Onondagas, to manage the salt springs, and in 1795 it acquired title to them and 10 sq.m. of surrounding land, in return for $1,000 in cash and promise of an annual rental of $700 and 150 bushels of salt. In 1797 the State began leasing the salt lands, on a royalty basis. Three villages soon sprang up around the southern end of the lake: Webster's Landing and Salina in 1797 and Geddes (founded by James Geddes, the first manufacturer

of salt on a pretentious scale) in 1803. "The Landing" was known by several names in succession until 1820, when a post-office was established and the name of Syracuse was adopted, after the ancient Greek city in Sicily. It was incorporated as a village in 1825, became the county seat in 1827, and in 1847 Syracuse and Salina were consolidated and chartered as a city. The population in 1850 was 22,271. From time to time various annexations of contiguous territory have been made, including the village of Geddes in 1886 The salt industry was the foundation of the city's development. Until about 1870 it was the dominating industry and Syracuse was the principal source of supply for the United States Not only was this industry the basis of most of the early individual fortunes in Syracuse, but pressure from the men interested in salt-making crystallized the demand for the Erie canal, the first section of which, passing through Syracuse from Rome to the Seneca river, was opened in 1820. As the salt industry declined, a variety of new and diversified manufactures sprang up In the 1890's Syracuse made thousands of bicycles, and by 1900 it was one of the principal centres for the manufacture of typewriters.

SYR-DARYA (Gr. and Lat. *Jaxartes;* Arab *Shash* or *Sihun*), (1) a river of Asiatic Russia, flowing into the Sea of Aral, and having a length of 1,500 m. and a drainage area of about 320,000 sq. miles. Its headstream is the Naryn, rising in the Tianshan south of Lake Issyk-kul, on the south slope (12,000 ft.) of the Terskei Ala-tau. After union with the Barskaun, it flows W.S.W. at 11,000 to 10,000 ft. above the sea, in a barren longitudinal valley between the Terskei Ala-tau and the foothills of the Kokshal-tau. As the Naryn it flows through a wild gorge in the south-west continuation of the Terskei Ala-tau, falling 4,000 feet. Fort Narynsk, 20 m. below the confluence of the Great and the Little Naryn, is only 6,800 ft. above the sea. Here the river enters a broad valley—formerly the bottom of an alpine lake—and flows past the ruins of Fort Kurtka, for 90 m. westward, as a stream some 50 yd. wide and from 3 to 11 ft. deep, used by the Kirghiz for irrigating their cornfields. The At-bash, a large mountain stream, joins the Naryn at the head of this valley and the Alabuga or Arpa at its lower end, both from the left. Before reaching the lowlands the Naryn cuts its way through three ridges which separate the valley of Kurtka from that of Ferghana, and does so by a series of wild gorges and open valleys (170 m), representing the bottoms of old lakes; the valleys of the Toguztorau, 2,000 ft. lower than Kurtka, and the Ketmen-tube are both cultivated by the Kirghiz. Sweeping north, the river enters Ferghana—also the bottom of an immense lake—where, after receiving the Kara-darya (Black River) near Namangan, it assumes the name of Syr-darya. The Kara-darya is a large stream rising on the northern spurs of the Alai mountains. As it deflects the Naryn towards the west, the natives look upon it as the chief branch of the Syr-darya, but its volume is less. At the confluence the Syr is 1,440 ft. above sea-level.

On issuing from this gorge the Syr enters the Aral depression, and flows for 850 m. in a north-westerly and northerly direction before reaching the Sea of Aral. On this section it is navigated by steamers. Between the Irjar rapids and Baildyr-turgai (where it bends north) the river flows along the base of the subsidiary ranges which flank the Chotkal mountains on the north-west, and receives from the longitudinal valleys of these alpine tracts a series of tributaries (the Angren, the Chirchik, the Keles).

Some 50 m. below Chinaz (770 ft. above sea-level) the Syr bends northwards, but resumes its north-westerly course 150 m. farther down, following with remarkable persistency the edge of the loess. Its low banks, overgrown with reeds and rendered uninhabitable in summer by clouds of mosquitoes, are inundated for 20 m. on both sides when the snows begin to melt. These inundations prevent the moving sands of the Kyzyl-kum desert from approaching the Syr; below Perovsk (Kzyl-Orda, or Ak Mechet) the steppe conquers. Down to Perovsk the river rolls its muddy yellow waters, at the rate of 3 to 5 m. an hour, in a channel 300 to 600 yd wide, and 3 to 5 fathoms deep; at Perovsk its vertical section is 8,220 sq ft, and 312,500 cu.ft. of water are discharged per second The Arys and the Bugun are the only tributaries worthy of notice along this part of its course; the other streams which descend from the Kara-tau fail to reach the river. The Kirghiz rear numerous herds of cattle and sheep in the valley of the Arys, while lower down, as far as Julek, the Iginchis carry on agriculture. All this applies of course only to the right bank; on the left the moisture is absorbed by the hot winds which cross the Kyzyl-kum sands towards the river. The dryness of the atmosphere has a marked effect upon the Syr when it gets below Julek, the Kara-kum sands being then on its right. Ten miles below Perovsk the river traverses a marshy depression (the bottom of a lake not yet fully dried up), where it divides into two branches—the Jaman-darya and the Kara-uzyak. The latter spreads out into marshes and ponds, from which it again issues to join the former at Karamakchi, after a course of 80 miles. The main arm, owing to its shallowness and sinuosity, is very difficult to navigate, and the difficulty is increased by the rapidity of the current and the want of fuel. Between Kazalinsk and the Sea of Aral (158 ft) navigation becomes somewhat easier, except for the last 10 m., where the river divides into three shallow branches before entering the "Blue sea." All three have at their mouths sandy bars with only 3 ft. of water

Two former right-hand tributaries of the Syr—the Chu and the Sary-su—now disappear in the sands some 60 m before reaching it. The Chu, which is 600 m in length, rises in the Tian-shan south-west of Lake Issyk-kul, and as the Kashkar flows towards Lake Issyk-kul, but a few miles before reaching that lake turns suddenly to the north-west, enters under the name of Chu the narrow gorge of Buam, and, piercing the snow-clad Kunghei Ala-tau, emerges on its northern slope, having descended from 5,500 ft. to less than 2,000 in a distance of not more than 50 miles. In this part of its course it receives from the right the Kebin, whose high valley equals in size that of the upper Rhone. It then flows north-westwards through the valley of Pishpek, and, avoiding the Muyun-kum sands, describes a wide curve to the north before finally taking a western direction. Numberless streams flow towards it from the snow-clad Alexander mountains, but they are for the most part lost in the sands before reaching it. The Talas, 170 m. long, formerly an affluent of the Chu, which rises in the highest parts of that range, pierces the Cha-archa mountains, and, flowing past Aulie-ata on the south border of the Muyun-kum, enters the salt lake of Kara-kul 60 m from the Chu. The Chu terminates in the Saumal-kul group of lakes, 60 m. from the Syr. Another elongated group of lakes—the Uzun-kul—near the above, receives the Sary-su, which has a length of nearly 570 m and flows rapidly in a narrow channel along the western edge of the northern Famine Steppe (Bekpak-dala)

The delta of the Syr begins at Perovsk, whence it sends a branch to the south-west, the Jany-darya (New River), which formerly reached the south-eastern corner of the Sea of Aral, very near to the mouth of the Amu-darya. The Kirghiz affirm that a canal dug for irrigation by the Kara-kalpaks gave origin to this river. It had, however, but a temporary existence. A dam erected by the people of Khokand at Ak-mechet (Perovsk) caused its disappearance, and the Russians found nothing but a dry bed in 1820. When the dam was removed the Jany-darya again reappeared, but it failed to reach the Sea of Aral; in 1853 it terminated in Lake Kuchka-denghiz, after a course of 250 m.; all traces of its bed were then lost in the sand. Five centuries ago, in the time of Timur, the Mongol prince of Samarkand, the Jany-darya brought the waters of the Syr to the Daukara lakes, close by the present mouth of the Amu. The series of old river-beds in the Kyzyl-kum, which are still seen above Perovsk, indicate that the Syr had a constant tendency to seek a channel to the south-west, and that its present delta is but a vestige of what it was once. At a still more remote period this delta probably comprised all the space between the Kara-tau and the Nura-tau in Samarkand; and the series of elongated lakes at the base of the Nura-tau—the Tuz-kaneh and Bogdan-ata lakes—represent an old branch of the delta of the Syr which probably joined the Zarafshan before reaching the Amu. The cause of this immense change is simply the rapid desiccation of all northern and central Asia. The extension of the Caspian sea as far as the Sary-kamysh lakes

during the post-Pliocene period and the extension of the Sea of Aral at least 100 m. to the east of its present position are both proved by the existence of post-Pliocene marine deposits.

(P. A. K.; J. T. Be.)

(2) A former province of Asiatic Russia, now included in the Kazakstan A.S.S.R. and Uzbek A.S.S.R. (*qq.v.*)

SYRIA, an independent State of south-west Asia placed under the mandate of France (1920). The region is bounded west by the Mediterranean, south by Palestine, east by Mesopotamia and north by Turkey. The area of Syria under the French mandate is estimated at 60,000 sq.m. and the population at under 3,000,000. Syria has been used as a name to include various expanses of country in south-western Asia. Some early Muslim geographers included all the Hamād in Syria, making its boundaries a blunt-headed triangle with a base some 700 m. long resting on the North Arabian Nefud. But Strabo, Pliny and Ptolemy, as well as Muslim geographers, drew the eastern frontier obliquely from the Gulf of Aqaba to Rakka (Raqqa) on the Euphrates and thus placed the Hamād in Arabia.

The name *Syria* is not found in the original Hebrew of the Scriptures; but it was used by the Septuagint to translate Aram. Homer knows only Ἄριμοι, but Herodotus speaks of "Syrians" as identical with Assyrians, the latter being, he thinks, a "barbarian" form, and he applies the name very widely to include, *e.g.*, north Cappadocians ("White Syrians" of Pteria). Syria, however, is probably the Babylonian *Suri*, used of a north Euphratean district, and a word distinct from Assyria. Generally the ethnic term, Syrian, came to mean in antiquity the Semitic peoples outside the Mesopotamian and Arabian areas; but neither in pre-Greek nor in Greek times had the word Syria any precise geographical significance, the various lands retaining their distinctive status, *e.g.*, Commagene (Kummukh), Cyrrhestica, Phoenicia, Palestine, etc. It is only under the Graeco-Roman administration that we find a definite district known as Syria and that was at first restricted to the Orontes basin. All that was understood until 1914 by Syria came to be so known officially to the Romans and Byzantines; but the only province called simply Syria, without qualification, remained in the Orontes valley.

Syria, under the French mandate, is a section of the great ancient block of which Arabia, Sinai and Africa also form part. This old block rises steeply from the Mediterranean to about 10,000 ft. and then falls in a series of long steps eastward to the basin of the Upper Euphrates, which flows in a great structural depression between the ancient block and the newer and loftier fold mountains of Kurdistan beyond. In the extreme north of French mandated Syria a section of these fold mountains forms part of the orography.

A marked feature of the old block section is that it is deeply gored by fracture lines, which run mainly in a north to south direction. The 34° N. parallel, which passes near Baalbek, marks a watershed from which may be traced the Orontes (Nahr el 'Āsi) flowing northward among the fracture lines and the north Lītāni, in its upper course, flowing southward. The Jordan valley continues the great north to south fault into Palestine whence it may be followed southwards via the Dead sea and the gulf of Aqaba into East Africa. The Orontes, after flowing northwards past the 36° N. parallel, turns abruptly westward and occupies the depression between Jebel Akra and the Amanus mountains. In this valley is Antioch. The southward-flowing Lītāni repeats this on the south when it turns abruptly westward through the upper Cretaceous of Lebanon and becomes known in its lower course as the Kasimiya. Numerous smaller streams flow westward into the Mediterranean from the mountains of Lebanon (*q.v.*) and Jebel Nuseiriye. The latter is a high chain of Jurassic limestone with basaltic intrusions, whose peaks rise to 10,000 ft. and whose passes do not fall under 6,000 ft. To the east of the Orontes-Lītāni-Jordan fracture is the triple chain of Jebel al Ala in the north defining the Orontes valley on the east. Like its western parallel it springs up to the south into a lofty chain known as Jebel esh Sharqi (Anti-Lebanon) (*see* Lebanon), which culminates on the south in the outstanding peak of Hermōn (8,000 ft.). Thereafter the mountain ranges lose much of their distinctive character.

To the east of the mountains lie the desert and steppe lands. Oases in a series are fed by local streams. Of these the most important are the Saltpan of Jebeil in the north fed by the North al-Dahab; the oases of Kinnesrin and Aleppo, fed by the North Kuwaik and that of Sham or Damascus fed by streams from Hermōn, of which the Barada (Abana) and the Acwaj (Pharpar) are the chief. Marine Pliocene beds have been found at El Forklus in the Palmyra desert. To the west of the mountain ridges lies the coastal plain. It is very narrow in the south from Tyre (Es Ṣur) to Tripoli, but widens out in the north especially near the river mouths. The coast (with the exception of the delta sections) shows marked north to south lines. These seem related structurally to the great north to south faults among the mountains. The few indentations of the coastline limit the natural harbours, but where local circumstances have been favourable (*e.g.*, a small island off Tyre and a small promontory near Beirūt) some of the great harbours of the ancient world grew up. On this coast, it was said, the east and west met. Thus behind the mountains were the great bazaars—Damascus, Antioch, Awa and Aleppo—and on the coast the great ports, Tyre, Sidon, Acre, Beirūt, Tripoli, Latakia and Alexandretta.

Climate.—The coastal strip of Syria has the best climate, because it is exposed to the moderating influences of the Mediterranean. The westerly rain-bearing cyclonic storms bring rain in winter to this part which has the heaviest fall in the south (Beirūt 21·66 in. mean annual rainfall). Among the mountains of Lebanon the rainfall often exceeds 40 inches. The coast lands are also less affected by intense heat, owing to the sea influences, the mean annual temperature at Beirūt being 68°. Where the cooling sea winds are shut off by the mountains, as at Aleppo and Damascus, the heat is intense. In winter the dense, cold, dry anticyclonic influences of central Asia spread over the plateau regions of Syria, giving frost and snow among the mountains; but this is never experienced along the coast. The interior steppe gives great contrasts of temperature both seasonal and diurnal, although the rainfall is always slight. In early summer a hot, dry wind, often bringing large quantities of sand, blows out from the desert and often damages the vegetation of the coastal regions. These general climatic conditions mean that Syria, except the narrow littoral strip, which was the ancient Phoenicia, and the small deltas, such as that of Latakia (Laodicea), is not highly productive without irrigation. The larger rivers (*e.g.*, the Orontes) flow in deep beds and are thus of little use for irrigation purposes. Mid-Syria, except for the lacustrine oases, is a region mainly occupied by pastures and yielding only thin cereal crops. The plains south and south-east of Aleppo have a little spring rain giving a good spring pasture which has attracted the nomads from farther south. Below the latitude of Raqqa-Homs thin steppe begins, and quickly degenerates into desert broken only by a chain of poor oases, south of a low ridge running from Anti-Lebanon to Euphrates. Of these the principal are Karietein and Tadmor (Palmyra), through which passes the trade from Damascus to the east.

Flora and Fauna.—Two distinct floral regions meet in Syria, that of the Mediterranean and that of the west Asiatic steppe-land. The first, to be seen on the coast and the western slopes of the highlands, is characterized by evergreen shrubs, and by quickly-flowering spring plants. On the lowest levels the southern forms, the *Ficus sycomorus* and the date-palm, appear, and increase in the direction of Egypt. (*See* Lebanon and Palestine.) The steppe region, whose flora appears east of the western ridge, is distinguished by the variety of its species, the dry and thorny character of its shrubs, and great poverty in trees. Among cultivated trees, the olive is at home throughout Syria, except on the steppe: the mulberry is planted extensively in the lower Lebanon; and all sorts of fruit-trees flourish in irrigated gardens, especially on the Phoenician coast, in the oases of Damascus, and in the Buka'a. The lower western slopes of the coast range are largely devoted to tobacco growing. In the northern inland hill-country liquorice grows wild. The mammals

of Syria include the isabelline bear, badger, pole-cat, ermine, roe and fallow deer, wild ass, Syrian squirrel, pouched marmoset, gerbill and leopard.

Population and Religion.—The population (1922) of the major divisions of Syria was as follows.—Syria 1,198,829, Lebanon 628,863, 'Alawis 261,062 and Jebel ed Drūz 50,328 Phoenicia and the Lebanon districts in the south coastal region have the densest population, while the oases of Damascus and Aleppo, the Orontes valley and parts of the extreme north-west are well-peopled The bulk of the population shows Semitic features The Aramaean element is fundamental though it has a large admixture of immigrant Arabian blood which is constantly being reinforced In the extreme north the highlands are almost entirely held by Kurds who entered from beyond Euphrates in comparatively recent times Kurds live upon the Commagenian plains, as also in the northern trans-Euphratean plains Among them in the Taurus and Amanus, and outnumbering them on the plains, formerly lived Armenian communities, many of whom have become refugees in mandated Syria. These are found as far south as the plain of Antioch and the basin of the Sajur To the north of Aleppo and Antioch live remnants of pre-Aramaean stocks, mixed with many half-settled and settled Turkomans (Yuruks, Avshars, etc), who came in before the Mohammedan era, and here and there colonies of imported Circassians Mid-Syria shows a medley of populations, in large part alien, for which *see* DRUSES, MARONITES, and LEBANON In the Phoenician coast towns are many Greeks In the steppe-land are numbers of true Arabs, mostly belonging to the great Anazeh family, which has been coming northwards from Nejd in detachments since the 13th century. Turks and various Europeans complete the medley.

The bulk of the population is Mohammedan Besides orthodox Muslim there are also Shī'ite sects, as well as followers of old religions modified by Islam such as the Ismailites (Assassins), *q v*, Metawali, Nosairis, Ansarieh, and especially the Druses (*q v*) The Jews are found mainly in the larger centres of population. The Christians are an important element and have had churches in Syria since the earliest times There are three uniate patriarchs and one orthodox patriarch of Antioch Arabic is the prevailing language though it has many local dialects Survivals of Aramaic are in the remote villages of Anti-Lebanon From the upper Sajur northwards Turkish prevails, but many Kurdish communities retain their own tongue.

Education.—The American university of Beirūt was founded in 1866 There were 934 students in 1923–24. There is also a Jesuit university in Beirūt founded in 1875 The French have about 500 schools with 50,000 pupils, while the Greek Catholics have a seminary at Ain Traz near Beirūt, and a patriarchal college in the city The Maronites, Roman Catholics and British missionary societies have educational institutions There are high grade schools at Aleppo, Damascus and Brummāna and a training college at Beirūt

Government.—Until 1914 Syria was a province of Turkey-in-Asia. By decision of the Supreme council of the Allied powers after the World War of 1914–18 Syria was recognized in 1920 as an independent State to be placed under the mandate of France. This was confirmed by the League of Nations in 1922 The country was originally divided into five regions (*états*) but since 1925 the *états* of Damascus and Aleppo have been united to form the territory of Syria (Sanjaqs of Hamā, Homs, Damascus, Haurān, Aleppo, Alexandretta and Deir ez Zor) The other regions are 'Alawis (Sanjaks of Latakia and Tartūs), Great Lebanon, and Jebel ed Drūz The Great Lebanon (*q.v.*) was proclaimed a State in 1920 with Beirūt as the seat of government. Syria is administered by a high commissioner.

Communications.—There has been a great improvement in the roads during the 20th century. In 1924 Syria had 4,021 m. of roadway of which 1,384 m. were fit for motor traffic. Railway communication is also good, lines run from Beirūt to Homs, Hamā, Aleppo (Haleb) and Damascus The latter is connected via Der'ā in the extreme south with Haifa and northern Palestine generally. The following sections of railway were opened in 1925, Beirūt to Damascus; Riyāq Mameltein to Aleppo, Homs to Tripoli; Beirūt to Damascus to El Hammé

Commerce and Trade.—The great caravan trade with the east that made Syria and the Levant so important in the middle ages and long before, has now almost entirely ceased. Syria is mainly an agricultural country with large areas given over to cattle and sheep rearing About 10% of the area of mandated Syria, including the Haurān, raises crops, of which wheat, barley and millet are the most important. Over a million tons (estimate) of wheat were raised in 1925. Sesame, from which oil is produced is a valuable but uncertain crop. About 4,700 ac. in Latakia Aleppo, Beirūt and Damascus produce about three million pounds of tobacco A marked feature of recent developments in Syria (1920–28) is the extended cultivation of cotton In 1922 5,000 tons were produced, two years later this had reached 30,000 tons Sugar cane and hemp are also important The white mulberry is grown in the north to feed silk-worms Oranges, lemons and bananas are important among the exports. (E G. Bow.)

ANCIENT HISTORY

Rude stone monuments (circles and dolmens) and other prehistoric remains are an indication that Syria must have been inhabited from an extremely early period Within historic times a great number of different nationalities have fought and settled within its borders, the majority belonging to the Semitic stock This last circumstance has rendered possible a considerable degree of fidelity in the tradition of the oldest local names After the Aramaeans had absorbed what remained of the earlier population, they themselves were very powerfully influenced by Graeco-Roman civilization, but as a people they still retained their Aramaean speech Of the political relations of Syria in the most ancient times we know but little Each town with its surrounding district seems to have constituted a small separate State, the conduct of affairs devolved upon the noble families In the latter part of the 16th century B C. all north Syria fell under the Cappadocian Hatti domination. The south part of Syria was known to Sargon of Akkad (*Agade*) as Ammon and was visited by his armies This is known as the Canaanite period, succeeded about 1000 B C. by the Aramaean As early probably as the 16th century B C Syria became the meeting-place of Egyptian and Babylonian elements; a type of western Asiatic culture resulted which through the commerce of the Phoenicians was carried to the western lands of the Mediterranean basin Industry especially attained a high state of development, rich garments were embroidered, and glass, pastes, faience, etc were manufactured. The influence exercised on Syrian art by the powerful neighbouring states is confirmed by recent finds which show the action of the Aegean culture on Phoenicia and Palestine. The Syrians were more original in what related to religion; every place, every tribe, had its "lord" (Ba'al) and its "lady" (Ba'alat), the latter is generally called 'Ashtar or 'Ashtaret (*i e*, Ishtar, Astarte). Besides the local Ba'al there were "the god of heaven" (El) and other deities, human sacrifices not uncommon

Something about the ancient political and geographical relations of Syria can be gleaned from Egyptian sources, especially in connection with the campaigns of Tuthmosis (Thothmes) III (*see* EGYPT, *History*), in western Asia and the administration of Amenophis (Amenhotep) IV. (the Tell el-Amarna Letters) The Egyptians designated their eastern neighbours collectively as 'Amu Syria up to and beyond the Euphrates is called more precisely Sahi and is regarded as consisting of the following parts (1) Rutenu, practically the same as Palestine (occasionally Palestine with Coelesyria is called Upper Rutenu, as distinguished from Lower Rutenu extending to the Euphrates), (2) the land of the Kheta (sometimes reckoned as belonging to Rutenu with Kadesh on the Orontes as its capital in the Ramesside period); (3) Naharina, the land on both sides of the Euphrates (extending, strictly speaking, beyond the Syrian limits). The Canaanites in general are called Kharu. From these lands the Egyptian kings often derived rich booty, so that in those days Syria must have been civilized and prosperous Moreover, we possess enumerations of towns which can be readily identified, such as Aleppo, Kadesh, Sidon, as well as many in Palestine. The Tell el-Amarna

Letters (15th century B.C.) show Syria held in part by Egyptian viceroys, who are much preoccupied with southward movements due to pressure of Amorite peoples, and of the Mitanni and the Kheta, whose non-Semitic blood was mingled with that of the Aramaeans even in Palestine. On the latter in Syria, *see* HITTITES. It need only be said here that this people bulked most largely in the relations of Egypt with Syria from the 16th to the 14th centuries. During the reign of Rameses II. it was centred on the upper Orontes (Kadesh). Later we find Kheta focused farther north, on the middle Euphrates (Carchemish), and more or less cut off from Egypt by the Hebrew State. They remained, however, the most powerful of the Syrian elements until the westward extension of Assyria about 1050 B.C., under Tiglath-Pileser I. Late in the 8th century Sargon III. took Carchemish and ended Hittite power.

With the fall of the Kheta the Aramaeans were the people who held the most important towns of Syria, gradually advancing until at last they occupied the whole country. Of the Aramaean stocks named in Gen. x. 23, xxii. 21 *et seq.* very little is known. A great part was played in the history of Israel by the State of Aram Dammesek: *i.e.*, the territory of the ancient city of Damascus; it was brought into subjection for a short time under David. The main object of the century-long dispute between the two kingdoms was the possession of the land to the east of the Jordan (Hauran, and especially Gilead). Hamath in the valley of the Orontes was from an early period one of the most important places in Syria; according to the Bible, its original inhabitants were Canaanites. In 733 B.C. Tiglath-Pileser II. compassed the overthrow of the kingdom of Damascus; he also took Arpad (Tel Arfad), an important place three hours to the north of Aleppo. Hamath was taken by Sargon in 720. Henceforward the States of Syria were subject to one or other of the great world-empires, and were still in dispute between Babylonia and Egypt as late as Necho. Thereafter the Mesopotamian powers prevailed, even if in some cases a certain degree of independence was preserved; *e.g.*, by the Phoenician cities. These, however, in spite of more than one revolt, continued to supply fleets to the Persians down to the time of the Macedonian invasion (332 B.C.).

The foundation of numerous Greek cities after Alexander's time was of great importance for Syria (see *e.g.*, ANTIOCH). The Graeco-Syrian civilization extended far to the south down both sides of Jordan, and, but for the Maccabaean revival, would have absorbed the Jews. The Seleucidae had severe struggles with the Ptolemies for the possession of the southern part of Syria (*see* MACEDONIAN EMPIRE).

After having been reckoned from 83 to 69 B.C. among the dominions of Tigranes, king of Armenia, the country was conquered for the Romans by Pompey (64–63 B.C.). It is of special interest to note that the kingdom of the Arab Nabataeans was able to keep its hold for a considerable period on the north as far as Damascus. The country soon became one of the most important provinces of the Roman Empire; its proconsulship was from the first regarded as desirable, and this eminence became still more marked afterwards. Antioch, adorned with many sumptuous buildings, as the chief town of the provinces of Asia, became in point of size the third city of the empire. The high degree of civilization then prevailing in the country is proved by its architectural remains.

The administrative divisions of Syria during the Roman period varied greatly at different times. Hadrian made three provinces of it, Syria, Syria Phoenice and Syria Palestina. At the beginning of the 5th century we find the following: (1) Syria Euphratensis, which had for its capital Hierapolis (*q.v.*). (2) Syria I., or Coelesyria, having Antioch as its capital. The name Coelesyria (ἡ κοιλὴ Συρία), no doubt, was applied originally to the valley ("hollow") between Lebanon and Anti-Lebanon, but was afterwards extended to the district stretching eastwards from the latter range. (3) Syria II., or Syria Salutaris, with Apameia as capital. (4) Phoenice Maritima; capital, Tyre.' (5) Phoenice ad Libanum; capital, Emesa (Homs). To this division Damascus and Palmyra belonged. (6, 7, 8) Palestina I., II. and III. (9) Arabia (capital, Bostra), which embraced all the region from the Hauran to the Arnon, and skirted the Jordan valley, stretching southwards to Petrae. Through the kingdom of the Nabataeans Roman influence penetrated from Syria far into northern Arabia.

In A.D. 616 Syria was subjugated for a brief period by the Persian Chosroes II.; from 622 until 628 it was again Byzantine; 636 and the immediately following years saw its conquest by the Mohammedans (*see* CALIPHATE). During the struggles of the Mohammedan dynasties for the possession of Syria the country still enjoyed a considerable degree of prosperity.

In the period of the crusades the kingdom of Jerusalem, whose rulers were never able to establish a foothold to the east of the Jordan, extended northwards to Beirut; next to it lay the countship of Tripoli on the coast; and beyond that in north Syria was the principality of Antioch. Syria suffered severely from the Mongol invasions (1260), and it never recovered its former prosperity. In 1516 the Ottomans took it from the Egyptian Mamelukes (*see* TURKEY: *History*). Its mediaeval importance as an intermediary of trade between Europe and the East was impaired by the opening of the Red sea route, and abolished by the Suez Canal. For the archaeology of Syria *see* ASIA MINOR: *Archaeology*. (D. G. H.; X.)

MODERN HISTORY

Syrian Nationalism.—One result of the Turkish revolution of 1908 was to give an impetus to the Nationalist movement which had begun, some years before, to gain ground in the Arabic-speaking provinces of the Turkish empire, and especially in Syria.

It was not until 1912, when Turkey was reeling under the shock of the Balkan wars, that it was thought that something should be done to conciliate the Arabs. Kiamil Pasha, who became grand vizier towards the close of the year, allowed a national assembly to be convened at Beirut for the purpose of formulating the Syrian demands. The assembly met in Jan. 1913, but its proceedings were annulled by Mohammed Shevket Pasha, who succeeded Kiamil a few weeks later. In June 1913 a so-called Arab congress was held in Paris. The members were drawn mainly from what may be called the French sphere of influence in the Lebanon and Beirut. The congress adopted a comparatively moderate programme, including the usual demand for decentralization, and resolved that it should be communicated, not only to the Turkish Government, but to foreign Powers in friendly relations with Turkey.

The Turkish Government was sufficiently impressed to invite three Muslim members of the congress to visit Constantinople. Another conciliatory gesture was the recall of the Vali of Beirut, an uncompromising opponent of concessions to the Arabs, and the appointment of a more liberal-minded successor. A little later a number of Arabs, including some of the militant reformers, were given seats in the Turkish Senate or lucrative appointments in the civil service. By these means the Turks succeeded in buying off some of their opponents, but on the main points at issue they continued to temporize, and the Syrian demands received no substantial satisfaction. The situation in Syria was watched with special vigilance in Paris. On Dec. 21, 1912, the prime minister, M. Poincaré, declared in the Senate that "we have traditional interests in the Lebanon and Syria, which we intend to have respected." On the eve of the World War France was busily engaged in strengthening her position in the Levant against German competition, and was negotiating for the acknowledgment, on a *do ut des* basis, of her prior claim to concessions in Syria and Palestine.

When Turkey entered the war, in Oct. 1914, France promptly asserted her claims in the Levant, and so far as Syria was concerned, as distinct from Palestine, they were never questioned. As between Great Britain, France and Russia the matter was disposed of in the spring of 1916 by a tripartite agreement, which was elaborated as between Great Britain and France by the so-called Sykes-Picot agreement. This agreement, which was concluded on May 16, 1916, gave France virtually a free hand on the Syrian coast, with a veiled protectorate over the interior.

War Conditions.—In Syria itself it looked at first as though the outbreak of war had given the Nationalists their opportunity. But the tide soon turned against them. Among the French consu-

lar archives which were seized in Syria the Turks claimed to have discovered evidence of treasonable dealings with France on the part of a number of the Nationalist leaders This was the signal for a series of executions and deportations, which began in the summer of 1915 and continued for the next 12 months. For the time being, at least, the Nationalist agitation was completely cowed. Syria had, indeed, little chance of giving trouble. Except for an occasional raid on the coast, it did not become a theatre of war until the eve of the Armistice and had no opportunity—even if it had the desire—to co-operate with the Allies In the autumn of 1918 Gen. Allenby, at the head of the British forces in Palestine, having expelled the Turks from Palestine, swept on after them through Syria, and the Armistice which came into force on Oct 31, 1918, left the whole of Syria in the hands of the Allies.

Post-war Settlements 1918–24.—On Nov 7, 1918, the British and French Governments issued a joint declaration, in which they announced their intention of establishing, both in Syria and Mesopotamia, "national governments drawing their authority from the initiative and free choice of the native populations " Meanwhile the Syrian sea-board, including Beirut, was placed in charge of the French, while the interior was handed over to an Arab Government which was set up at Damascus under the emir Feisal, both areas remaining as occupied enemy territory under the general supervision of Lord Allenby as commander-in-chief. On Sept 15, 1919, Great Britain and France signed a convention by which the Syrian seaboard came under the direct and exclusive control of France. The interior remained under the administration of the emir Feisal, but it was now brought within the French sphere of influence, and ceased to be under the general control of the British commander-in-chief. The anti-French agitation conducted by the Arab Nationalists came to a head in March 1920, when an Arab congress met at Damascus and declared "the complete independence of Syria, without any form of foreign interference." At the same time, Feisal was proclaimed king of Syria. Great Britain and France united in refusing to recognize the Syrian kingdom, but the Damascus Nationalists remained defiant The end came in July 1920, when a French ultimatum to the Arab Government was followed by an advance into the interior, the flight of the emir Feisal, and the entry of French troops into Damascus

Meanwhile, Syria had been under discussion at the Peace Conference in Paris, where it was the subject of a complicated, and at times acrimonious, exchange of views between Great Britain and France It was eventually agreed in principle that the situation in Syria should be examined on the spot by an international commission of enquiry, but all that actually happened was that two American delegates, Dr King and Mr Crane, spent a few weeks in Syria in the summer of 1919 They reported that a French mandate would be wholly unacceptable and recommended that the Mandatory Power should be the United States, with Great Britain as a second-best. The King-Crane report, however, had no influence on the course of events, and on April 25, 1920, the Supreme Council of the Allies formally agreed at San Remo that the mandate for Syria should be allotted to France. The terms of the mandate were approved by the Council of the League of Nations on July 24, 1922, but further delays intervened, and the mandate did not become fully effective until Sept 29, 1923 The situation was finally regularized by the formal detachment of Syria from the Ottoman empire under the Treaty of Lausanne, which came into force in Aug. 1924.

French Administration.—It was, however, the French occupation of the interior in the summer of 1920 which marked the opening of the new régime by bringing the whole country under direct French control The Lebanon, which the French had occupied at the Armistice, was recognized in Sept 1920, by the League of Nations as a separate "State," with an area considerably larger than the pre-war province. The Lebanon was predominantly Christian, and its administration involved the absorption of a large number of unwilling Muslims. Inner Syria was broken up into the "States" of Damascus and Aleppo, together with the "Territory of the Alawiyin," with its capital at Latakia. In July 1922 the three divisions of Syria proper, as distinct from the Lebanon, were given an opportunity of co-operating in matters of common concern through the medium of a federal council. By a decree dated Dec. 5, 1924, the federation was dissolved, the States of Damascus and Aleppo were amalgamated into the State of Syria, and the State of the Alawiyin became a separate unit.

The Druse Rebellion.—Syria contains many turbulent elements, and the French had repeatedly to deal with unrest in various parts of the mandated territory. In 1919–20 they met with determined resistance in the Djebel Ansariyeh, the northern neighbour of the Lebanon. There was serious rioting at Damascus in 1922 and again in 1925. In the Alexandretta district, in the extreme north of Syria, the French were constantly harassed by Turkish raids across the border, while they also had some trouble with the tribesmen of the desert frontier on the east. In the Druse country in the Hauran there was scarcely a quiet year until 1923, and it was here that the signal was given for the widespread rising which closely followed the arrival of Gen Sarrail as high commissioner, in succession to Gen Weygand, at the beginning of 1925. The Druses rose in open rebellion in July Their initial successes brought to the surface the latent discontent which existed in other parts of Syria, and it looked for the moment as though the French would be faced with a general rising A serious situation developed at Damascus, and on Oct. 18–20 the French took the extreme measure of subjecting the city to a 48-hour bombardment By the end of 1925 the weak French garrison in Syria had been considerably strengthened, and the insurrection had been checked, though by no means completely suppressed In Dec 1925 Gen. Sarrail was superseded as high commissioner by Henri de Jouvenel, whose declared policy was one of conciliation De Jouvenel was not, however, conspicuously successful Nationalist opposition defeated his attempt to form a provisional Syrian Government under the sheikh Taju'd-Din, while in some parts of the country, notably at Damascus, the population boycotted the elections which he ordered to be held as a first step towards a *modus vivendi* By the middle of 1926 the back of the rebellion had been broken, though the country remained restless.

The circumstances of the rising were closely investigated, on behalf of the League of Nations, by the permanent Mandates Commission at a special session held in Rome in Feb and March 1926 The commission, in its report to the League Council, convicted the French of serious errors of policy and severely censured the conduct of Gen Sarrail, though at the same time it recognized the difficulties of the mandatory power.

In June 1926 de Jouvenel appeared in person before the Mandates Commission to report progress The gist of his statement was that France looked forward to an eventual settlement on the lines successfully followed by Great Britain in 'Iraq, but that the real difficulty was that Syria was a medley of warring sects and races which it would take time to weld into a nation Article I of the mandate required France to provide Syria with a permanent Constitution in the shape of an organic law within three years of the date on which the mandate came into force. The time-limit expired on Sept 29, 1926, but on Sept. 20 the Council of the League agreed to a six months' extension. The Mandates Commission took note of this decision at its meeting in Nov. 1926, but it returned to the subject in reporting to the Council on the situation in Syria in July 1927, when it drew attention to the fact that the organic law had not yet been promulgated At the end of 1927 the linked problems of Syrian constitution and of the relations between Syria and France still awaited a final solution

Though in this respect the situation remained anomalous, the pacification of Syria had made considerable progress since the Druse rebellion began to flicker out in the spring of 1926. The embers of the rising still smouldered, but the crisis was over, and in the end the Druse leaders either fled the country or made their peace with the victors. In May 1926 de Jouvenel succeeded in setting up a Syrian Government under Ahmed Nami Bey, though it was a Government which derived its authority from the high commissioner and not from any representative assembly. In the State of the Alawiyin the representative council resumed its sittings in Oct. 1926, but Syria as a whole remained without constitutional machinery through which it could negotiate a permanent

settlement with the Mandatory Powers. On the other hand, an increased measure of autonomy was granted to the Lebanon, which was formally proclaimed a republic on May 23, 1926, while in the Alexandretta district the situation was eased by the signature on May 30, 1926, of a Franco-Turkish treaty defining the frontier between Syria and Turkey and guaranteeing Syria against Turkish raids.

In Aug. 1926 de Jouvenel was succeeded as high commissioner by Henri Ponsot, who arrived in Syria in October, was recalled to Paris for consultation with the Home Government a few months later and returned to his post in June 1927. By this time, though there was still much latent unrest, Syria could no longer be said to be out of hand. On July 27, 1927, M. Ponsot made his eagerly awaited statement of policy. Its key-note was *festina lente.* France undertook to encourage the political evolution of the various Syrian States and to promote co-operation between them in matters of common concern, but she was non-committal on the subject of Syrian unity and independence. M. Ponsot's first important step after the publication of this statement was one which caused much dissatisfaction in the Lebanon. He insisted on a drastic modification of the Lebanon Constitution of 1926. The senate was to be abolished, and half the members of the chamber, instead of being popularly elected, were to be nominees of the Lebanese Government. To these unpopular proposals the Lebanese parliament eventually agreed, under protest, on Oct. 12, 1927.

On the French side public opinion was moving in the same direction, and on Dec. 14, 1927, the foreign affairs committee of the senate passed a resolution urging that definite proposals with regard to the future administration of Syria should be put forward without delay. In Feb., 1928, M. Ponsot announced that elections would shortly be held for a constituent assembly. The immediate sequel was the resignation of Ahmed Nami Bey as president of the Syrian State in favour of Sheikh Taju'd-Din who had been M. de Jouvenel's original choice for the same appointment. M. Ponsot next proceeded to issue a series of decrees abolishing the censorship of the Press, terminating the state of siege, declaring an amnesty (with certain exceptions) for political offenders, and giving the franchise to all citizens who had attained the age of 21. Polling took place in April, 1928, and resulted in the election of a constituent Assembly of a predominantly Nationalist complexion.

The assembly met at Damascus on June 9, and proceeded to frame an elaborate constitution, of which the outstanding feature was that Syria was declared to be an independent republic with Damascus as its capital. It was further declared that Syria was one and indivisible, and that the post-war territorial charges (including the enlargement of the Lebanon and its recognition as a political unit distinct from Syria) were null and void. M. Ponsot pointed out that the proposed constitution ignored the existence of the mandate, and would make it impossible for France to discharge her obligations as the Mandatory Power. His remonstrances, however, were ineffectual. The assembly was obdurate, and in August, a deadlock having been reached, M. Ponsot suspended the sittings of the assembly for three months. Thus, in the autumn of 1928 the gulf between the Mandatory Power and the people of the mandated territory was still unbridged, and although Syria was outwardly quiet, the Syrian problem seemed as far as ever from a solution. SYRIAC LANGUAGE. Syriac is the name given to the language used by Christian writers in the region east of Antioch, including the Christian subjects of the Persian empire. It seems to have been originally the local Aramaic dialect of Edessa (*q.v.*), which became a centre of Christianity as early as the last third of the 2nd century. Edessa was till 216 the seat of a native monarchy, consequently the new religion took a vernacular form there, whereas inside the Roman empire no languages except the imperial Greek and Latin were used by Christians for literature or public worship until the 4th century. But the Bible and the forms of Christian liturgy having been translated into the Edessene dialect and publicly used, this dialect was accepted all over the East by native Christians as a classical literary language.

Since the 5th century A.D. owing to theological differences Syriac-using Christians have been divided into Nestorians or East Syrians and Jacobites (Monophysites) or West Syrians, and these groups are now linguistically distinguished by certain differences of pronunciation, chiefly in the vowels. The East Syrians in most cases have kept the more primitive pronunciation, *e.g.*, the old Semitic *ā* with them remained *ā*, but with the Jacobites passed into *ō*. The name *Jesus* is by the East Syrians pronounced *Isho'*, by the Jacobites *Yeshu'*. The language of the Maronites, a religious body now in communion with Rome and chiefly living in the Lebanon region, is in all respects the same as that of the Jacobites or West Syrians. Classical Syriac is now nowhere a spoken language. A variety of the Western Syriac survived till about 50 years ago in some villages near Damascus, and the Nestorians of the Tigris valley speak a modern dialect akin to the old East Syriac though differing considerably from it.

Writing.—Syriac has the same 22 letters as Hebrew. Their forms are ultimately derived from the Old Hebrew and Phoenician alphabets. The oldest mss., of the 4th and 5th centuries, are written in a very beautiful current hand known as *Estrangĕla*, the lapidary form of which is still preserved in some old inscriptions at Edessa. This gave place to other scripts from about the 9th century, the Jacobite form being less graceful and further removed from the *Estrangĕla* than the Nestorian. Speaking generally, this writing only indicates the consonants, the vowel *u* (short or long without distinction), long *i*, and final *a*. The other vowels, so long as Syriac remained a living language, were not indicated at all, or only partially indicated by a dot above or below the whole word. But about the time when Syriac began to be supplanted by Arabic two systems of vowel-signs were invented, one by West Syrians, who borrowed the forms of Greek vowels, and the other more elaborate by East Syrians, who used combinations of dots. These signs are written above and below the consonantal letters. Neither system completely distinguishes long from short vowels; the Nestorian system is more satisfactory, though more cumbrous.

Consonantal Permutations.—Syriac is a dialect of Aramaic (*see* SEMITIC LANGUAGES), and uses the same alphabet as Hebrew as remarked above. As in Hebrew the six letters *b g d k p t* are aspirated ($\beta\ \gamma\ \delta\ \chi\ \phi\ \theta$) when immediately preceded by any vowel sound. Thus "he wrote" is in Arabic *kataba*, in Hebrew kāθaβ

in Syriac *kθaβ*. We may note that the unwritten light vowel after *k* (light as *e* in "belong") aspirates the following consonant, but the second member of a diphthong is reckoned as a consonant, so that we get *baytā* ("house"), not *bayθā*

The peculiar dentals and sibilants of early Semitic, preserved almost in their original diversity in classical Arabic came to be pronounced differently in Hebrew and Syriac So we get

Arab.	*thālāthā*	Heb.	*shlōshā*	Syr	*tlāθā*	("three")
,,	*dhahab*	,,	*zāhāβ*	,,	*dahβā*	("gold")
,,	*'arḍ*	,,	*'areṣ*	,,	*'ar'ā*	("earth")
,,	*ẓuhr*	,,	*ṣohŏraim*	,,	*ṭahrā*	("midday")

In the Arabic *s* and *sh* sounds Syriac generally agrees with Hebrew against Arabic, but the details are too complicated to be given here.

Parts of Speech. (1) **Pronouns.**—As in Hebrew the personal pronouns exist in two forms: the longer is used as a nominative and is a separate word, the shorter is attached to verbs as an accusative and (in a slightly different form) to nouns as a possessive. These suffixes give rise to less change in the vowels of the words to which they are attached than in Hebrew. The relative pronoun is *d* (i e , *d* followed by the shortest kind of vowel), which is prefixed to words.

(2) **Nouns.**—There are two numbers, sing. and pl , and two genders, masc. and fem. Syriac, like all Aramaic dialects, has no definite article, but the noun has three "states"—absolute, construct, emphatic, e g , *rēsh*, "head," "a head"; *rēsh* (*malkā*), "the-head-of (the-king)"; *rēshā*, "the-head" But in Syriac the emphatic state (*rēshā*) has almost superseded the simple "absolute," which is hardly used except for adjectival or participial predicates and in certain stock phrases The construct, which, as in Hebrew, must be immediately followed by a genitive, is less used than in Hebrew, except as the form on which to hang the possessive suffixes. In its place the relative participle *d* is used; in place of *rēsh malkā* ("the-head-of the-king") we find *rēshā dmalkā*, *i e* , "the-head which-the-king (-has)," or *rēsheh dmalkā*, *i.e.*, "his head which (-is)-the king." Here the *d* is practically equivalent to our "of." This genitive (with prefixed *d*), does not require the governing noun to precede it immediately, as must be the case with the construct: in this and many respects Syriac has gained greater flexibility in syntax than Hebrew

The fem sing. ending is *-ā* (absolute), *-aθ* (construct), *-tā* or *θā* (emph): thus the fem sing. abs is always identical in form with the masc sing emph. The plural endings are. masc abs *-īn*, const *-ai*, emph. *-ē*, fem abs *-ān*, const *āθ* emph *-āθā*

(3) **Verbs.**—The most notable peculiarity of Syriac as compared with other Aramaic dialects, and indeed other Semitic languages generally, is that the prefix to the imperfect is *n*, not *y*, *e.g* , "he will write" is *neχtoβ*, not *yeχtoβ*: this is likely to have been originally a mere local peculiarity of the speech of Edessa The Syriac verb has lost the original passive forms still surviving in Arabic, and in their place uses reflexive forms, with prefixed *eθ-* and a change in the last vowel. The simple active *kθaβ* makes its passive *eθkθeβ*, the intensive *katteβ* makes *eθkattaβ*, and the causative *aχteβ* makes *ettaχtaβ*. (Note the changes made in the *b g d k p t* letters caused by the presence or absence of a preceding vowel)

In Syriac the verbs have become real tenses, partly with the help of the auxiliary *(h)wā*, a truncated form of *hwā* ("was") Thus we get Pres. *kāθeβ*, "he writes," "he is writing", Impf. *kāθeβ wā*, "he was writing"; Fut. *neχtoβ*, "he will write"; Subj *dneχtoβ*, "that he may write"; Aor. or Perf. *kθaβ*, "he wrote," "he has written"; Plupf *kθaβ wā*, "he had written"—sometimes also used for simple Aorist.

(4) **Particles and Syntax.**—Syriac uses a great many conjunctions, many of them adapted from Greek Thus we have *gēr* from γάρ, *dēn* from δέ (or at least used like Greek δέ), even *man* from μέν. The order of words which is permissible is also very free, more so than in any other Semitic language, a fact which gives to Syriac great flexibility and also renders word-for-word translation into it easier

In some Syriac translations from the Greek, notably the later Jacobite translations of the Bible and other Greek theological works, Greek idiom is very slavishly followed This, however, is to be regarded rather as learned pedantry than as linguistic evolution. In other works, *e.g.*, the Syriac version of Pseudo-Callisthenes *Life of Alexander*, which was translated not from the original Greek but from a Pahlavi text, the influence of the Persian idiom is quite perceptible in the syntax.

Christian Palestinian Syriac is the name given to a literature written not in "classical Syriac," but in the vernacular dialect of Palestine. It is exclusively theological (Bible, Homilies, Cyril's *Catecheses*, etc), and appears to date from the 5th or 6th centuries when certain emperors, notably Justinian, made belated efforts to evangelize the non-Greek-speaking populations of Palestine The documents are written in a peculiar script The language is very similar to the Jewish Targums and to some Aramaic parts of the Talmud unfortunately the linguistic value of this literature is greatly diminished by the fact that it wholly consists of translations from the Greek and follows the Greek idioms with painful literalness.

SYRIAC LITERATURE. The use of Syriac by Christians as a literary medium had its original centre in Edessa (Syr Ūrhāi, modern Urfa), where, in all probability, the chief Syriac versions of the Bible were made The use of the same dialect appears in the earliest Christian literature connected with such Mesopotamian cities as Nisībis, Amid, Mardīn, Taghrīth and Seleucia-Ctesiphon, as well as west of the Euphrates at such centres as Mabbōgh (Hierapolis) and Aleppo, northwards at Malatiah and Maiperkat and in the districts of Lake Van and Lake Urmia, and to the east and south-east of the Tigris in many places which from the 5th century onwards were centres of Nestorian Christianity within the Sassanian empire. In Palestine and western Syria, the home of pre-Christian Aramaic dialects, the vernacular Semitic speech had under Roman dominion been replaced by Greek for official and literary purposes Apparently this state of things lasted till after the Mohammedan conquest, for Barhebraeus tells us that it was the caliph Walīd I (A D 705–715) who, out of hatred to Christianity, replaced Greek by Arabic as the language of official documents at Damascus

Syriac literature continued in life from the 3rd to the 14th century A D, but after the Arab conquest it became an increasingly artificial product, for Arabic gradually killed its vernacular use

Religious Literature.—In the literature as it survives many different branches of writing are represented—homilies in prose and verse, hymns, exposition and commentary, liturgy, apocryphal legends, historical romance, hagiography and martyrology, monastic history and biography, general history, dogmatics, philosophy and science, ecclesiastial law, etc. But the whole is dominated by the theological and ecclesiastical interest. When we put aside one or two exceptionally fine pieces, like the hymn of the soul in the apocryphal Acts of Thomas, the highest degree of excellence in style is perhaps attained in straightforward historical narrative—such as the account of the Perso-Roman War at the beginning of the 6th century by the author who passes under the name of Joshua the Stylite, or by romancers like him who wrote the romance of Julian; by biographers like some of those who have written lives of saints, martyrs and eminent divines; and by some early writers of homilies such as Philoxenus (in prose) and Isaac of Antioch (in verse).

For the general history of culture the work of Syriac writers as *translators* is, perhaps, as important as any of their original contributions to literature. Beginning with the earliest versions of the Bible, which seem to date from the 2nd century A D, the series comprises a great mass of translations from Greek originals —theological, philosophical, legendary, historical and scientific. In a fair number of cases the Syriac version has preserved to us the substance of a lost original text. Often, moreover, the Syriac translation became in turn the parent of a later Arabic version. This was notably the case with some of the Aristotelian writings,

so that in this field, as in some others, the Syriac writers handed on the torch of Greek thought to the Arabs, by whom it was in turn transmitted to mediaeval Europe. The early Syriac translations are in many cases so literal as to do violence to the idiom of their own language; but this makes them all the more valuable when we have to depend on them for reconstructing the original texts. The later translators use greater freedom. It was not from Greek only that translations were made into Syriac. Of translations from Pahlavī we have such examples as the version of pseudo-Callisthenes' *History of Alexander*, made in the 7th century from a Pahlavī version of the Greek original—that of *Kalilah and Dimnah* executed in the 6th century by the periodeutēs Bōdh—and that of *Sindbad*, which dates from the 8th century; and in the late period of Syriac literature, books were translated from Arabic into Syriac as well as vice versa.

The Cradle of Syriac Literature.—All our historical sources support the view taken above that Edessa, the capital of the kingdom which the Greeks and Romans called Osrhoene, was the earliest seat of Christianity in Mesopotamia and the cradle of Syriac literature. But as to the date and circumstances of its evangelization we have little reliable information. The well-known legend of the correspondence of Abgar Ukkāmā, king of Edessa, with Christ and the mission of Addai to Edessa immediately after the Ascension was accepted as true by the historian Eusebius (d. 340) on the faith of a Syriac document preserved in the official archives of the city. An amplified form of the same story is furnished by the *Doctrine of Addai*, an original Syriac work which survives complete in a St. Petersburg (Leningrad) ms. of the 6th century, and is also represented by fragments in other mss. of the 5th and 6th centuries. This work was probably written at Edessa about the end of the 4th century. But whether in its longer or its shorter form, the whole narrative must be pronounced unhistorical. In all probability the first king of Osrhoene to adopt Christianity was Abgar IX., son of Ma'nū, who reigned from A.D. 179 to 214 or 216, and the legend has confounded him with an earlier Abgar, also son of Ma'nū, who reigned first from B.C. 4 to A.D. 7 and again from A.D. 13 to 50. (*See* Lipsius, *Die edessenische Abgar-Saga*, 1880.) A contemporary of Abgar IX. at Edessa was the famous Bardaiṣān, himself a convert from heathenism, who was of noble birth and a *habitué* of the Edessene court. It was no doubt partly under his influence—also possibly in part through impressions received by Abgar during his visit to Rome about A.D. 202—that the king's conversion took place. But Christianity must have reached Edessa some 30 to 50 years earlier. Our oldest native historical document in Syriac—the account of a severe flood which visited Edessa in Nov. A.D. 201—mentions "the temple of the church of the Christians" as overthrown by the flood. The form of this notice shows, as von Gutschmid and others have remarked, that Christianity was not yet the religion of the State; but it must for some time have had a home in Edessa. By a skilful piecing together of the data furnished by the oldest Syriac versions of the Bible—such as the derivation of the Old Testament version from the Jews, and the almost exclusive use of Tatian's Diatessaron as the gospel of the Syriac Church down to the beginning of the 5th century—F. C. Burkitt has shown it to be probable that the preaching of Christianity at Edessa reaches back to the middle of the 2nd century or even to about the year 135 (*Early Eastern Christianity*, Lecture II.).

The Syriac versions of the Bible are treated elsewhere (*see* BIBLE) and may here be dismissed with a brief summary of facts and opinions. The received Syriac Bible or Vulgate (called the Peshitta or "simple" version from the 9th century onwards) contains all the canonical books of the Old Testament. In the New Testament, 2 Peter, 2 and 3 John, Jude and the Apocalypse were originally left out, but Syriac versions were made at a later time. The Peshitta version of the Old Testament must have been originally made mainly by Jews, of whom we know there were colonies in Mesopotamia in the 2nd century. The translation was executed entirely from the Hebrew, but underwent later revision which brought it more into conformity with the LXX.—this to a greater degree in some books than in others. The Peshitta New Testament—according to the convincing theory which at present holds the field—is not the oldest form of the Syriac version, at least as regards the Gospels. From the beginning of the 3rd to the beginning of the 5th century Tatian's Harmony or Diatessaron —whether originally compiled in Syriac, or compiled in Greek and translated into Syriac—was the current form of gospel in the Syriac Church. The text of the Gospels underlying it "represents the Greek text as read in Rome about A.D. 170." Slightly later was made the Old Syriac version of the separate Gospels, which survives in two mss.—the Curetonian and the Sinaitic—in two differing forms: but this never obtained much currency. Its text "represents, where it differs from the Diatessaron, the Greek text as read in Antioch about A.D. 200." Then at the beginning of the 5th century, by the efforts of the masterful Rabbūlā, who was bishop of Edessa from 411–412 to 435, a new version or recension of the Gospels was made and incorporated in the Peshitta or Vulgate, the use of the Diatessaron being henceforth proscribed. Rabbūlā's text of the Gospels "represents the Greek text as read in Antioch about A.D. 400." The history of the Peshitta rendering of the Acts and Epistles is less clear.

Apocryphal Books.—Of the large number of Apocryphal books existing in Syriac the majority have been translated from Greek, one or two (such as *Bar Sīrā* or *Ecclesiasticus*) from Hebrew, while some (like the *Doctrine of Addai* above referred to) are original Syriac documents. Special mention may be made here of the tale of Aḥīḳār—the wise and virtuous secretary of Sennacherib, king of Assyria—and of his wicked nephew Nādhān. This is the Syriac version of a narrative which has had an extraordinary vogue in the world's literature. It is now known to have existed in Aramaic as far back as the 5th century B.C., appearing in Jewish papyri which were lately discovered by the German mission to Elephantine. It appears to be traceable in its Greek dress in writings of the philosopher Democritus and the dramatist Menander; it was certainly known to the author of Tobit and perhaps to the author of Daniel; some would trace its influence in the New Testament, in the parable of the wicked servant and elsewhere; it was known to Mohammed and is referred to in the Koran; it has been included among the tales in the *Arabian Nights;* and it survives in a good many versions ancient and modern. The old Syriac version, which is to be found in a number of mss., was probably made from an early Aramaic version, if not from the original itself (which must surely have been Semitic). The Syriac has in turn become the parent of the Arabic, Armenian and Ethiopic—possibly also of the Greek and Slavonic-versions. (*See* F. Nau, *Histoire et sagesse d'Ahikar l'Assyrien*, 1909.)

Another deeply interesting Syriac Apocryphon is the *Acts of Judas Thomas* (*i.e.*, Judas the Twin), which is included in the collection of *Apocryphal Acts of the Apostles*. The *Acts of Thomas* is now generally recognized to be an original Syriac work (or "novel," as Burkitt calls it), although a Greek version also exists. It seems to have arisen in Gnostic circles, and its tendency is wholly in favour of asceticism and celibacy. Among its peculiarities is the fact that Judas Thomas is regarded as the twin brother of Christ. The author has incorporated in it the finest poem to be found in all Syriac literature, the famous Hymn of the Soul.

Lives of the Saints.—Lives of saints and martyrs form a large group among Syriac books. Among such documents connected with the early history of Edessa we have, besides the *Doctrine of Addai*, certain martyrdoms, those of Sharbēl and Barsamyā assigned to the reign of Trajan, and those of Guryā and Shāmōnā and of the Deacon Habbībh under Diocletian and Lincinius. All these documents, like *Addai*, belong probably to the 2nd half of the 4th century, and are unreliable in detail for the historian though they may throw some light on the conditions of life at Edessa under Roman government. There are also accounts of martyrdoms at Samosāta (Assemani, *Acta Mart.* ii. 123–147), including that of St. Azazail published by Macler (Paris, 1902). But the great bulk of the Syriac martyrdoms have their scene farther east, within the Persian dominions.

The life and writings of Bardaisān, "the last of the gnostics," and in some sense the father of Syriac literature and especially of Syriac poetry, have been treated in a separate article. *The Book of the Laws of the Countries*, which embodies his teaching,

was re-edited in 1907 by F. Nau (this also in the 2nd volume of Graffin's *Patrologia*). Mention may here be made of the valuable edition and translation by the late C. W. Mitchell of *S. Ephraim's prose refutations of Mani, Marcion and Bardaisan. Transcribed from the palimpsest B. M. Add. 14628* (1912–21).

An early Syriac document, probably of the 2nd or 3rd century, is the *Letter of Mārā son of Serapion,* which was edited by Cureton in his *Spicilegium Syriacum.* It is almost the only exception to the rule that all surviving Syriac literature is Christian.

By the beginning of the 4th century much progress had been made with the organization of the Christian church not only within the Roman district of Mesopotamia, but also to the east and south-east within the Sassanian empire, round such centres as Seleucia-Ctesiphon on the Tigris (near Baghdad), Karkā dĕ-Bēth Sĕlōkh (modern Kerkuk) and Bēth Lāpāt or Gundēshābhōr (in the modern province of Luristan). The adoption of Christianity by Constantine as the official religion of the Roman empire had an unfortunate effect on the position of the Christians in Persia They were naturally suspected of sympathizing with the Roman enemies rather than with their own Persian rulers. Accordingly when Sapor II. (310–379) declared war on Rome about 337, there ensued almost immediately a somewhat violent persecution of the Persian Christians, which continued in varying degrees for about 40 years One result of this and later persecutions of the same kind has been to enrich Syriac literature with a long series of *Acts of Persian Martyrs,* which, although in their existing form intermixed with much legendary matter, nevertheless throw valuable light on the history and geography of western Persia under Sassanian rule.

4th and 5th Centuries.—The two most important 4th-century writers—Aphraates and Ephraim—are dealt with in separate articles. The importance of the former lies in the simple cast of his religious thought, his independence of theological formulas, his constant adherence to the letter of Scripture, his quaint exegesis, and the light he throws on the circumstances of his time, especially (1) the feeling between Jews and Christians, and (2) the position and sympathies of the Christian subjects of Sapor II. The position and character of Ephraim are very different. He is the typical exponent in Syriac of unbending Catholic orthodoxy

Before leaving the 4th century we may mention two other writers who probably both lived on into the 5th—Balai and Cyrillōnā. The former was the author of a good many poems; the longest—which is however by some attributed to Ephraim—is the work in 12 books on the history of Joseph, of which a complete edition was published by Bedjan in 1901. Other poems of his were edited by Overbeck in *S Ephraemi Syri,* etc., *opera selecta,* pp. 251–336; and these have since been supplemented by Zetterstéen's edition of a large number of his religious poems or metrical prayers (*Beiträge zur Kenntniss der religiösen Dichtung Balais,* Leipzig, 1902). His favourite metre was the pentasyllabic. Cyrillōnā composed a poem on the invasion of the Huns in 395.

The 5th century was a time of storm and conflict in the churches of Mesopotamia and Persia, as in other parts of the Christian world. The teaching of Apollinarius that in Christ the Divine Word took the place of the human rational soul, thus seeming to do away with his possession of a true humanity, had led to a reaction by Paul of Samosāta, Diodore of Tarsus, Theodore of Mopsuestia, and Nestorius of Constantinople. Though with some points of difference, they agreed in emphasizing the permanence of the two separate natures in Christ, united but not mingled or confused, and laid stress on the reality of our Lord's human experience. One question on which great contention arose was as to the propriety of applying to the Divine nature attributes which belonged to the human nature—*e.g.,* birth from a human mother—and vice versa. Hence the great dispute about the application to the Virgin Mary of the epithet *θεοτόκος*. It seems to have been the objection of Nestorius to the use of this expression which mainly led to his condemnation and deposition at the Council of Ephesus (431) under the influence of Cyril, although as patriarch of Constantinople (428–431) he had distinguished himself by his zeal for Nicene orthodoxy. New light on the theological position of Nestorius is to be obtained from the long-lost *Book of Heraclides,* a work of his own which has turned up in a Syriac version and was published by Bedjan in 1910.

At Edessa the result of the conflict between the Nestorians and their opponents was long doubtful. When Rabbūlā, the fierce anti-Nestorian and friend of Cyril, died in 435, he was succeeded in the bishopric by Ibas, who as head of the famous "Persian school" in the city had done much to inculcate on his pupils the doctrines of Theodore of Mopsuestia. But the feeling against the Nestorian party grew in strength, till on the death of Ibas in 457 the leading Nestorian teachers were driven out of Edessa The Persian school continued to exist for another 32 years, but was finally closed and destroyed by order of the emperor Zeno in 489. The Nestorian teachers then started a great school at Nisībis (which had been under Persian rule since Jovian's humiliating treaty of 363). By the energetic efforts of Barṣāumā, bishop of that city, practically the whole church of Persia was won over to the Nestorian creed.

Great Churchmen.—At the beginning of the 5th century one of the most able and influential men in the Syriac-speaking Church was Mārūthā, bishop of Maiperḳat or Martyropolis. Without entering on the details of his ecclesiastical activity, we may note that he was twice associated with embassies from the Roman emperor to Yazdegerd I. (399–420); that along with Isaac, patriarch of Seleucia (390–410), he obtained from the Persian monarch a concordat which secured a period of religious toleration, and that he arranged for and presided at the Council of Seleucia in 410, which adopted the full Nicene creed and organized the hierarchy of the Persian Church. As a writer he is chiefly known as the reputed author of a collection of martyrologies which cover the reigns of Sapor II., Yazdegerd I. and Bahram V. By his history of the Council of Nicaea he made a great contribution to the education of the Persian Church in the development of Christian doctrine.

The next bishop of Edessa, Ibas, who succeeded in 435 at the death of Rabbūlā, proved himself a follower of the Nestorian doctrine. (*See* above) As a teacher in the Persian school of Edessa he had translated, probably with the help of his pupils, certain works of "the Interpreter," *i.e.,* Theodore of Mopsuestia. Among these may have been the commentary on St. John of which the complete Syriac version was published by Chabot in 1897. He may possibly have translated a work of Aristotle. To the Nestorian movement in Persia he rendered useful service by his letter to Mārī of Bēth Hardashēr, in which he maintained the tenets of Diodore and Theodore, while allowing that Nestorius had erred. On the ground of his writings he was condemned and deposed by the "robber synod" of Ephesus (449), but was restored by the Council of Chalcedon (451), after he had anathematized Nestorius. His death in 457 was followed by a strong anti-Nestorian reaction at Edessa, which led to the expulsion of many of the leading teachers

On Isaac of Antioch, "one of the stars of Syriac literature," *see* the special article. In spite of his over-diffuseness, he is one of the most readable of Syriac authors

A Nestorian contemporary of Isaac, Dādhīshō', who was catholicus of Seleucia from 421 to 456, composed commentaries on Daniel, Kings and Ecclesiasticus. His chief importance in the history of the Persian Church lies in his having induced a synod of bishops to declare that church independent of the see of Antioch and of the "Western Fathers." (*See* J. Labourt, *Le Christianisme dans l'empire perse,* 1904, p 122 *seq.*)

The most powerful missionary of Nestorianism during the 2nd half of the 5th century was Barṣāumā of Nisībis, whom his opponents called "the swimmer among the reeds," *i.e.,* the wild boar. Born probably between 415 and 420 he imbibed Nestorian doctrine from Ibas at the Persian school of Edessa, but was driven out in 457 on the death of his master, and went to be bishop of Nisībis. In a succession of missionary journeys he succeeded, partly by persuasion and partly (if his enemies are to be believed) by violence, in attaching to Nestorianism nearly all the Christian communities of Persia, with the exception of Taghrīth, which was always strongly Monophysite. He had many quarrels with

his ecclesiastical superior the catholicus of Seleucia, but finally made peace with Acacius soon after the accession of the latter in 484. Among other severities towards the Monophysites, he persuaded the Persian king Pērōz (457–484) to banish many of them into the Roman dominions. One of his great aims was to secure for the Nestorian clergy freedom to marry, and this was finally sanctioned by a council at Seleucia in 486 (Labourt, *op. cit.*, chap. vi.). Barṣāumā must have been bishop of Nisībis for nearly 40 years, but was dead by 496. His writings seem to have been chiefly liturgical; he gave the first set of statutes to the school of Nisībis, which was founded during his bishopric.

His fellow-worker Narsai, whom the Jacobites called "the leper," but the Nestorians "the harp of the Holy Spirit," apparently accompanied Barṣāumā from Edessa to Nisībis, where according to Barhebraeus he lived for 50 years. Barṣāumā appointed him head of the new school, where he taught rigidly Nestorian doctrine. He was a copious writer, especially in verse. Many of his poems have now been published. (*See* Mingana, *Narsai, homiliae et carmina*, 2 vols. Mosul, 1905.) His theological position is clearly defined in a homily on the three doctors —Diodore, Theodore and Nestorius—published by the Abbé Martin in the *Journal asiatique* for July 1900.

To about the same period belongs *The book of Hierotheus* by the "pantheist" Stephen bar Sūdh-aite, which has recently been edited and translated by F. C. Marsh (1927).

Early Monophysites.—Among the early Monophysites were two of the best of Syriac writers—Jacob of Sērūgh and Philoxenus of Mabbōgh, who have been treated in special articles. The one wrote mainly in verse, the other in prose. *See* also JOSHUA THE STYLITE.

Another early Monophysite was Simeon of Bēth Arshām, who by a series of journeys and disputations within the Persian empire did all he could to prevent the triumph of Nestorianism among the Persian Christians. He had considerable success at the time, but the ground he had won was soon reconquered by his opponents, except at Taghrīth and the surrounding district. It was after a successful disputation in presence of the Nestorian catholicus Bābhai (497–502/3) that Simeon was made bishop of Bēth Arshām, a town near Seleucia. He made several journeys to Constantinople, where he enjoyed the favour of the empress Theodora. It was there he died, probably about 532–533. His biography was written by John of Asia in the collection of lives of eastern saints which has been edited by Land (*Anecd. syr.* vol. ii.). His literary productions consist only of a liturgy and two exceedingly interesting letters. The one has for its subject Barṣāumā and the other Nestorian leaders in Persia, and gives a highly malicious account of their proceedings. The other, which has been often edited, is an account of a severe persecution which the Himyarite Christians of Najrān in south-west Arabia underwent in 523, at the hands of the king of Yemen. (See *The book of the Himyarites*, a Syriac work edited and translated by A. Moberg, Lund, 1924.) As Simeon had repeatedly visited al-Ḥirah and was in touch with the Arab kingdom which centred there, his letter is a document of first-rate historical importance.

Mention should be made of two other early Monophysite leaders who suffered persecution at the hands of the emperor Justin I. (518–527). The one, John of Tellā, author of 538 canons, answers to questions by the priest Sergius, a creed and an exposition of the Trisagion. His life was written by his disciple Elias, and also by John of Asia. The other, John bar Aphtōnyā, was the founder of the famous monastery of Kenneshrē, opposite Jerābīs on the Euphrates, and wrote a commentary of the Song of Songs, a number of hymns and a biography of Severus, the Monophysite patriarch of Antioch (512–519).

The life of the great missionary bishop Jacob Burdĕ'ānā or Baradaeus, from whom the Monophysite Church took its name of Jacobite, belongs rather to ecclesiastical than to literary history. (*See* H. G. Kleyn, *Jacobus Baradaeus, de Stichter der Syrische monophysietische Kerk*, Leyden 1882.)

Translators from the Greek.—In Sergius of Rās'ain we find one of the best Greek scholars and ablest translators whom Syria has produced. Of his life little is known, and that little not wholly creditable. He wavered curiously in his ecclesiastical views, and ended by helping the persecutors of the Monophysite Church, to which he himself had belonged. He seems to have lived as a priest and physician at Rās'ain in Mesopotamia most of his life. About 535 he travelled on various ecclesiastical missions, and finally made a journey to Rome and thence to Constantinople (in this latter accompanied by the pope Agapetus). The result was to bring about the deposition and banishment of the Monophysites from the latter city. Sergius died almost immediately afterwards, in 536. Among the works which he translated into Syriac and of which his versions survive are treatises of Aristotle, Porphyry and Galen, the *Ars grammatica* of Dionysius Thrax, the works of Dionysius the Areopagite, and possibly two or three treatises of Plutarch. His own original works are less important, but include a "treatise on logic, addressed to Theodore (of Merv), which is unfortunately imperfect, a tract on negation and affirmation; a treatise, likewise addressed to Theodore, *On the Causes of the Universe, according to the Views of Aristotle, showing how it is a Circle;* a tract *On Genus, Species and Individuality;* and a third tract addressed to Theodore, *On the Action and Influence of the Moon, explanatory and illustrative of Galen's* Περὶ κρισίμων ἡμερῶν, bk. iii., with a short appendix 'On the Motion of the Sun'" (Wright). According to the historical compilation which passes under the name of Zacharias Rhetor, he also wrote a treatise on the faith. Some of his translations were revised at a later time by Honain ibn Isḥāḳ (d. 873).

Another translator from Greek was Paul, Monophysite bishop of Callinīcus or ar-Raḳḳah, who, being expelled from his diocese in 519, retired to Edessa and there occupied himself in translating into Syriac the works of Severus, the Monophysite champion who was patriarch of Antioch from 512 to 519. This version appears to be quite distinct from that used by the compiler of the chronicle of Zacharias, and also from the version of "the 6th book of the select letters of Severus" which was made by Athanasius "presbyter of Nisībis" in 669, edited by E. W. Brooks (1902–04).

That important legal work, *The Laws of the Emperors Constantine, Theodosius and Leo*, which was composed in Greek about 475, and "which lies at the root of all subsequent Christian oriental legislation in ecclesiastical, judicial and private matters" (Wright), must have been repeatedly translated into Syriac. The oldest form is contained in a British Museum ms. which dates from the earlier part of the 6th century, and this was edited by Land (*Anecd. syr.* i. 30–64). A later (probably Nestorian) recension is contained in a Paris ms., which was used along with the other by Bruns and Sachau in their exhaustive edition (*Syrisch-römisches Rechtsbuch*, Leipzig, 1880). In *Notulae syriacae* (privately printed 1887) Wright edited the surviving fragment of a 3rd recension which is preserved in a 13th-century ms. at Cambridge. Finally Sachau has published three new redactions of the treatise from a ms. found at Rome in 1894 (*Syrische Rechtsbücher*, vol. i., Leipzig, 1907).

Anonymous Works.—We may here take note of three important anonymous works, of which the first probably and the other two certainly belong to the 6th century.

The Mĕ'arrath gazzē or *Cave of Treasures*, translated and edited by C. Bezold (Leipzig, 1883–88), is akin (as Duval remarks) to the *Book of Jubilees*. It is an imaginary history of the patriarchs and their descendants.

The tripartite narrative which is known as the *Romance of Julian* (the Apostate) has no claim to be regarded as an historical document. Its hero is Jovian, one of the feeblest of Roman emperors, and Julian is everywhere exhibited in flaming colours as the villain of the story.

A valuable historical source, though of small dimensions, is the *Chronicle of Edessa*, which gives a record of events from 132–131 B.C. to A.D. 540—at first exceedingly brief, but becoming somewhat fuller for the later years. It appears to be thoroughly reliable wherever it can be tested. It has been three times edited—first by Assemani in the *Bibliotheca orientalis* (i. 388–417), secondly by L. Hallier (Leipzig, 1892) with a translation, introduction and abundant notes, and thirdly by Guidi with a Latin version

(in *Chronica minora*, Paris, 1903).

On John of Asia or Ephesus, the eminent Monophysite bishop and earliest Syriac church historian, *see* the separate article.

An historical work of somewhat similar character to John's is the compilation in 12 books which is generally known by the name of Zacharias Rhetor, because the anonymous Syriac compiler has incorporated the Syriac version or epitome of a lost Greek history written by that author. The Syriac work exists (not quite complete) in a British Museum ms of about the beginning of the 7th century: this can be in part supplemented by an 8th-century ms. at the Vatican. From the latter Guidi published the interesting chapter (X 16) which contains the description of Rome The entire text of the London ms. was published by Land in the third volume of his *Anecdota syriaca;* and there is now an English translation by Hamilton and Brooks (1899), and a German one by Ahrens and Kruger (Leipzig, 1899).

Of the other 6th-century Jacobite writers we need mention only Moses of Aggēl (*fl c* 550–570) who translated into Syriac some of the writings of Cyril, and Peter of Callinīcus, Jacobite patriarch of Antioch 578–591, who wrote a huge controversial treatise in 4 books, each of 25 chapters, against Damian, patriarch of Alexandria, as well as other less important works.

The Nestorian writers of the 6th century were numerous, but as yet we know little of their works, beyond what 'Abhdīsho' tells us in his *Catalogue.* It will be sufficient to mention one or two Joseph Hūzāyā (*i e.,* of al-Ahwāz or Khūzistan), who came third in succession to Narsai as head of the school of Nisībis, was the first Syriac grammarian and invented various signs of interpunction Mārūthā, who was Nestorian catholicus of Seleucia from about 540 to 552 (*see* Labourt, *op. cit*, pp. 163–191), and a man of exceptional energy, made the only known attempt, which was, however, unsuccessful, to provide the Nestorians with a Bible version of their own. He was the author of many commentaries, homilies, epistles, canons and hymns Paul the Persian, a courtier of Khosrau Anōsharwān, dedicated to the king a treatise on logic which has been published from a London ms. by Land in the 4th volume of his *Anecdota.* Bōdh the periodeutes is credited with a philosophical work which has perished, but is best known as the author of the old Syriac version of the collection of Indian tales called *Kalīlah and Dimnah* He made it doubtless from a Pahlavī version His translation, which was edited by Bickell with an introduction by Benfey, must be distinguished from the much later Syriac translation made from the secondary Arabic version and edited by Wright in 1884, of this there is an English translation by Keith Falconer (1884) Ḥannānā of Ḥĕdhaiyabh, who nearly produced a disruption of the Nestorian Church by his attempt to bridge over the interval which separated the Nestorians from Catholic orthodoxy, was the author of commentaries

Decay in the 7th Century.—"With the 7th century," as Wright remarks, "begins the slow decay of the native literature of the Syrians, to which the frightful sufferings of the people during the great war with the Persians in its first quarter largely contributed." The same process of decay was greatly promoted by the Arab conquest of Persia, achieved through the victory of Ḳādisīya in 636–637 The gradual replacement of Syriac by Arabic as the vernacular language of Mesopotamia by degrees transformed the Syriac from a living to a dead language. Apart from a few leading writers—such as Jacob of Edessa, the anonymous historian whose work has passed under the name of Dionysius of Tell-Mahrē, Thomas of Margā, Dionysius bar Ṣalībī, and Barhebraeus (*qq v*)—there are few names of interest.

1. *Theology.*—Here we may first mention George, bishop of the Arabs (d. 724), who wrote commentaries on Scripture, and tracts and homilies on church sacraments, and finished the *Hexaëmeron* of Jacob of Edessa. Bābhai the Elder, a leading Nestorian in the beginning of the 7th century and a prolific author, wrote many commentaries and theological discourses Īshō'yabh III., Nestorian catholicus from 647 to 657/8, wrote controversial tracts, religious discourses and liturgical works. Elias of Merv, who belongs to the 2nd half of the 7th century, compiled a *Catena patrum* on the Gospels and wrote many commentaries. Timothy I., catholicus 779–823, wrote synodical epistles and other works bearing on church law. Moses bar Kēphā (d. 903), one of the most fertile of 9th-century authors, wrote commentaries, theological treatises and many liturgical works Other important contributors to this sphere of literature were Īshō' bar Nōn (d 827/8), John bar Zō'bī (beginning of the 13th century), Jacob bar Shakkō (d. 1241), and the great Nestorian scholar 'Abhdīshō' (d. 1318).

2 *History.*—Besides the important writers treated in separate articles, we need mention only four. Elias bar Shīnāyā, who in 1008 became Nestorian bishop of Nisībis, was the author of a valuable *Chronicle,* to which are prefixed numerous chronological tables, lists of popes, patriarchs, etc, and which covers by its narrative the period from A D. 25 to 1018 Of this work, which exists in only one imperfect copy, the later portion was edited by Baethgen in 1884, and the earlier by Lamy in 1888 Another important *Chronicle* is that of Michael I, who was Jacobite patriarch from 1166 to 1199. Its range extends from the Creation to the author's own day, and it was largely used by Barhebraeus in compiling his own *Chronicle.* Till recently it was known only in an abridged Armenian version which was translated into French by V. Langlois (Venice, 1868) · but the Syriac text was found in a ms. belonging to the library of the church at Edessa, and has been published by J. B. Chabot A work rather legendary than historical is the *Book of the Bee,* by Solomon of al-Basrah, who lived early in the 13th century Lastly, acknowledgment must be made of the great value of the Catalogue of Nestorian writers, by 'Abhdīshō' of Nisībis, the latest important writer in Syriac It was edited by Assemani in the 3rd part of his *Bibliotheca orientalis,* and has been translated into English by Badger.

3 *Biography, Monastic History, etc*—Besides the important work by Thomas of Margā (*q v*) the following deserve special mention Sāhdōnā, who was a monk in the Nestorian monastery of Bēth 'Ābhē (the same to which Thomas of Margā belonged two centuries later) and afterwards a bishop early in the 7th century, wrote a biography of and a funeral sermon on his superior Mār Jacob who founded the monastery, and also a long treatise in two parts on the monastic life of which all that survives has been edited by P Bedjan (Paris, 1902). Whilst accompanying the catholicus Īshō'yabh II (628–644) on a mission to Heraclius, Sāhdōnā was converted, apparently to Catholicism (*see* H. Goussen, *Martyrius-Sahdonas Leben und Werke,* Leipzig, 1897), and thereby caused much scandal in the East The chief events in his life are narrated by Ishō'dĕnah Another Nestorian who, a few years later, wrote ecclesiastical biographies and other theological works was Sabhrīshō' Rustam, who lived at Mount Īzlā and other monasteries In the beginning of the 8th century David of Bēth Rabban, also a Nestorian monk, wrote, besides a geographical work, "a monastic history, called *The Little Paradise,* which is frequently cited by Thomas of Margā" A more important work is *The Book of Chastity,* by Ishō'dĕnah, who according to 'Abhdīshō' was bishop of Ḳasrā—but read Basrā—about the end of the 8th century. This work is a collection of lives of holy men who founded monasteries in the East, and is a valuable historical source The work itself, or an abridgment of it, was discovered and published for the first time by J B Chabot (Rome, 1896) As the last under this head we may mention a late anonymous biography, that of the catholicus Yabhalāhā III. (1281–1317), which throws much light on the relations of the early Mongol kings with the heads of the church in their dominions Among other interesting features it contains information about the Nestorian Church of China in the 13th century

4 *Philosophy and Science*—Special mention may be made of 'Ānānīshō' of Ḥĕdhaiyabh (middle of 7th century) well known as the author of a new recension of the *Paradise* of Palladius, and also the author of a volume on philosophical divisions and definitions; Romanus the physician (d 896), who wrote a medical compilation, a commentary on the Book of Hierotheus, a collection of Pythagorean maxims and other works; Moses bar Kēphā, the voluminous writer above referred to; the famous physician Ḥonain ibn Ishāk (d. 873), who wrote chiefly in Arabic, but deserves mention here by his services to Syriac grammar and lexicography, and still more by his translations of Greek philosoph-

ical and scientific works into Syriac and from Syriac into Arabic, becoming in a sense the founder of a school of translators; and Jacob bar Shakkō, whose work called the *Dialogues* treats of grammar, rhetoric, poetry, logic, philosophy and science.

5. *Grammar and Lexicography.*—Several of the authors in this department have already been mentioned. The more important, besides Jacob of Edessa and Barhebraeus, are 'Anānīshō' of Ḥēdhaiyabh, Ḥonain ibn Isḥāḳ, his pupil Bar 'Alī, Bar Sarōshwai (early 10th century), Bar Bahlūl (middle of 10th century), Elias of Ṭīrhān (d. 1049), Elias bar Shīnāyā (above), John bar Zō'bī (beginning of 13th century) and Jacob bar Shakkō.

Apart from the numerous editions of Syriac texts by Paul Bedjan, some of which have been cited above, nearly all the texts recently edited are included in one or other of three comprehensive series now running—viz., (1) *Patrologia syriaca* (Paris, 1894); (2) *Corpus scriptorum christianorum orientalium—scriptores syriaci* (Paris, 1907); (3) *Patrologia orientalis* (Paris, 1907). *See* W. Wright, *History of Syriac Literature* (1895); R. Duval, *La Littérature syriaque* (3rd ed. 1907); A. Baumstark, *Geschichte der syrischen Literatur* (1922). (N. McL.)

SYRINGA, the common name applied to several cultivated ornamental shrubs of the family Saxifragaceae (*q.v.*). The name arose from the fact that the original generic name of these shrubs was *Syringa,* which, however, properly belongs to the lilac (*q.v.*), the garden syringas being now known botanically as species of *Philadelphus.* They possess conspicuous, usually strongly scented flowers and in a wild state are natives of the north temperate zone. There are about 20 species.

The common garden syringa (*P. coronarius*) is a native of Europe. Noteworthy North American species are the scentless syringa (*P. inodorus*), the large-leaved syringa (*P. grandifolius*) of the south-eastern United States, and the western syringa (*P. Lewisii*), the State flower of Idaho, found from Montana to British Columbia and Oregon.

SYRINGE, a hydraulic instrument, based on the principle of the pump, for the drawing up and ejecting of liquids. The ordinary form is that of a glass or metal tube ending in a pointed nozzle and fitted with an airtight piston-rod and handle. The nozzle is inserted in the liquid, which enters the cylinder by atmospheric pressure when the piston-rod is drawn up. On pushing back the piston the fluid is ejected in a jet through the nozzle. In sizes varying from the needle-pointed hypodermic syringe to the abdominal syringe, it is a common surgical implement used for the injection of fluids into the body or for the washing of wounds and cavities. A larger syringe of metal with a flat perforated nozzle is used as a garden implement for watering plants.

SYRINX, the Greek name for the pan-pipes. The pipes composing it were stopped at one end, so that the sound waves had to travel twice the length of the pipe, giving out a note nearly an octave lower than that produced by an open pipe of equal length. It consisted of a varying number of reeds, having their open ends in a horizontal line and their stopped ends, formed by the knots in the reed, gradually decreasing in length from left to right. Each pipe gave out one note, but by overblowing, *i.e.* increased pressure of breath and tension of lips, harmonics could be obtained. The syrinx or pan-pipes owes its double name to ancient Greek tradition, ascribing its invention to Pan in connection with a well-known legend of the Arcadian water-nymph Syrinx.

Syrinx is also a term used in medicine and anatomy, meaning (1) the Eustachian tube; (2) a fistula; and (3) a kind of secondary larynx found in birds.

SYRYENIANS (also Sirianian, Syrjenian, Zyrenian, Zirianian, Zyrian and Zirian), a tribe of the Permian division of the eastern Finns. Their headquarters are at Ust-Ishma, at the junction of the Ishma and Pechora. Formerly they spread farther to the west. They are of moderate stature, blond and grey-eyed, energetic and inclined to trade. They were converted to Christianity about 1350 and their language was reduced to writing. They call themselves Komi and are not sharply distinguished from the tribes known as Permian, the languages being mutually intelligible. The archaeological remains in the governments of Perm and Vyatka called Chudish by Russians are probably Syryenian. A grammar of the language was published by Castrén, and linguistic and other notices of the tribe are contained in the *Journal de la société finno-ougrienne,* especially for 1903.

SYZRAÑ, a town of Russia, in the Ulyanovsk province, in lat. 53° 10′ N., long. 48° 33′ E., near the right bank of the Volga. Pop. (1926) 48,458. It is on the Moscow-Kazan railway and has a branch going to Ryazan. There are flour mills, leather factories and saw-mills. Bricks and nails are manufactured and there is a brewery and a distillery. The town was originally a fort to protect settlers from Tatar and Circassian raids, but has developed, especially since the railway reached it, into a manufacturing centre, with river and rail trade in exported grain and imported timber and manufactured goods.

SYZYGY (sĭ'zĭ-jĭ), in astronomy, either of the points at which the moon is most nearly in a line with the earth and sun. The moon passes her syzygies, or is in a syzygy, at new and full moon.

SZÉCHENYI, ISTVAN, Count (1791–1860), Hungarian statesman, the son of Ferencz Széchenyi and the countess Juliana Festetics, was born at Vienna on Sept. 21, 1791. Entering the army in his 17th year, he fought with distinction at the battle of Raab (June 14, 1809), and on July 16 brought about the subsequent junction of the two Austrian armies by conveying a message across the Danube to General J. G. Chasteler at the risk of his life. Equally memorable was his famous ride, through the enemy's lines on the night of Oct. 16/17, 1813, to convey to Blücher and Bernadotte orders for the impending battle of Leipzig. In May 1815 he was transferred to Italy, and at the battle of Tolentino scattered Murat's bodyguard by a dashing cavalry charge. From Sept. 1815 to 1821 he travelled widely, studying the institutions of the countries through which he passed. A second—scientific—tour with his friend, Baron Miklos Wesselényi, taught him much about trade and industry. In 1825, when he went to France to attend the coronation of Charles X., the canal du Midi attracted his attention and suggested to him the idea of regulating the rivers Danube and Theiss. At the diet of 1825, when the motion for founding a Hungarian academy was made by Pál Nagy, who bitterly reproached the Magyar nobles for so long neglecting their mother-tongue, Széchenyi set the example by offering to contribute a whole year's income (60,000 florins) towards it. The formation (June 1833) of the Danube Navigation Company, which eventually opened up the Danube from Buda to the Black Sea was the fruit of Széchenyi's initiative and personal study. Széchenyi was also the first to start steamboats on the Theiss, the Danube and the lake of Balaton.

All this time Széchenyi had been following, with some anxiety, the political course of Kossuth, whose extravagances he feared would plunge Hungary back into the chaos out of which he had helped to raise her. The majority, indeed, sided with Kossuth, but neither this fact nor the gradual loss of his popularity restrained Széchenyi, both in the diet and at county meetings, from fulminating conscientiously against the extreme demands of Kossuth. His views at this period are expounded in the pamphlet *Politikai programm töredékek* ("Fragments of a Political Programme"). He held the portfolio of ways and communications in the first responsible Magyar administration (March 23, 1848) under Bátthyány, but his increasing apprehension of a revolution, with its inevitable corollaries of civil war and a rupture with the dynasty, finally affected his mind, and on Sept. 5 he was removed to an asylum. Here he remained for many years, but recovered sufficiently to correspond with his friends and even to meditate writing fresh books; but the sudden death of his old friend Baron Samuel Jósika and the once more darkening political horizon led him, in a moment of despair, to take his own life (April 8, 1860). He richly deserved the epithet "the greatest of the Magyars" bestowed upon him by his political antagonist Kossuth.

See Antál Zichy, *Biographical Sketch of Count Stephen Széchenyi* (Hung.; 2 vols., 1896–97).

SZECHUAN, the largest province of China Proper, area formerly nearly 220,000 sq.m., but since the institution of Kham (Chwanben) reduced to 160,000–185,000 sq.m., with a population only less dense than that of Shantung, recent estimates varying from 54,500,000 to about 61,500,000. The heart of Szechuan is the plateau known as the Red basin, a region that

continued as a gulf of the sea for some time, in later Palaeozoic period, after the north Mongolian region became land, and changed to a freshwater lake during the Mesozoic, with deposition of the post-Rhaetic red sandstones, later wrinkled and converted into land. The province is bordered on the west by the immense eastern Tibetan fault-zone, which gives a rapid rise from the Min-ho (less than 1,500 ft. above sea-level) by broad terraces to great north-south mountain lines, the greater part of which is well over the 12,000 ft. level. Most of this western highland is now included in the province of Kham (Chwanben) save that the Liangshan and some other mountains involved in great river-bends remain in south-west Szechuan. There is much evidence of a long continuance of earth movement along this great fault line, and the river courses of the highland have adapted themselves to the changes involved, running southward between the ranges turning eastwards into south-west Szechuan and north Yunnan, eventually uniting in the north-eastward course of the Yangtze-Kiang The mountain courses of the rivers are torrential; in the Red basin the rivers are generally navigable and afford the best means of communication On the north-east, the Red basin grades up to the Tapaling or Tapashan, beyond which, to the north, is the great west-east range of the Tsinlingshan. The Tapaling (Tapashan) end in a great fault against the Hupeh basin, eastwards; and the latter is much lower than the Red basin. The Yangtze-Kiang makes its way from the one down to the other through the famous gorges of the north-east frontier of Szechuan to Ichangin Hupeh. Von Richtofen thought that the sinking of the Red basin, as compared with the Tibetan highland, has continued until recent times, whereas that of the Hupeh basin, as compared with the Tapaling and the Red basin, ended earlier. The result would be a tilt, lessening the slopes in the west of Szechuan, within the basin, but increasing them in the north-east; this furnishes at least a supplementary interpretation of the Yangtze-Kiang (*q.v*) gorges, which are so notable a feature of China's physical geography, and have played such a part in isolating Szechuan from Hupeh. The Yangtze and its feeders within the basin in the west are less closely encased, so there are considerable alluvial plains, as around Cheng-tu, the capital, where irrigation is highly developed. Beyond the Yangtze-Kiang, to the south-east, stands the limestone horst of the province of Kweichow, with its border towards the Red basin, often at an altitude of 4,500 ft, drained by streams which reach the deep channel of the Yangtze by narrow valleys. The name Szechuan means four rivers, and the Yangtze-Kiang is made up of the Min, To, Fu and Kialing, flowing north to south into the Red basin, where they meet the Kin-Sha or Upper Yangtze, which has also been formed of north to south streams and has then rounded the Liangshan and flowed north along its eastern side, really entering the basin at Sui-fu (Su-chow-fu) where the Min, from Chengtu, joins it.

The climate of the Red basin may be studied from data for Chung-king, at the junction of the Kialing with the Yangtze. The monthly average temperatures vary from 49° F in December and January to 80°–82° F in July and August The average minimum per month is not more than 2–2·5° below the average, so, in the Red basin, snow and frost are not often lasting. The rainfall, very low under the influence of the Central Asiatic anti-cyclone in December, January and February, but March has a rainfall of 2·8 in., April a rainfall of 4 in., and so the amount increases up to a maxima of about 11 in in each of the months of June and August. The early onset of rain before the summer monsoon has begun is probably explained by the heating of the air in the deep basin and the consequent development of cyclones, which thus milden the climate of a region in the heart of a continent. The winter is not too cold for growth of cereals (wheat, barley, oats, millet) and the summer monsoon gives opportunities for almost tropical crops at low levels, and rice (especially on irrigated alluvium near Chengtu), sugar, hemp, sesamum, pulses, mulberry, oranges, maize and tobacco are thus grown. Wax trees are important around Kiating-fu. (*See* SUI-FU.)

Until the last millennium B.C. Szechuan was entirely non-Chinese, and was under Indian culture influence, the results of which persist in the cultivation of sugar-cane, the use of great water-wheels for irrigation, and the presence of the zebu and water-buffalo. The Tsin dynasty incorporated Szechuan within the empire, but its isolation has often made it a basis for separatist movements. The population within the basin has become definitely Chinese, though almost forming a separate nationality within the Chinese group. The western highlands have a sparse Tibetan population, while in the south-west are non-Chinese groups, Lolo, Sifan, Miautse, some probably of very long standing locally, others of relative late, if still pre-Chinese, entry.

The population reaches 550 per sq.m. in the east and centre, near Chungking (*q.v.*), the commercial focus (pop. 600,000), going up to 900 per sq.m. on the irrigated land near Chengtu (*q v.*), the capital (pop 400,000). Wanhsien, Sui-fu, Luchow, Shunking, Fowchow and Huchow all appear to have over 100,000 inhabitants each. In spite of the numerous large centres, 90% of the population is rural, living mostly in large villages.

The mineral resources of the province are little developed, owing to difficulties of extraction and transportation. Coal, mainly bituminous and associated with iron, is mined by adits along the Yangtze valley, and supplies the river steamers plying the 348 m. between Chungking and Ichang (Hupeh province). Other coal and iron producing centres are the Min and Kialing valleys. Copper is mined west of the Min river, where Ning-Yuan and Ya-Chow prefectures are the main producing districts. Salt extraction by brine pumping is also a widely prevalent activity. Gold, silver, lead and antimony are also mined, mainly west of the Min river.

Trade is severely handicapped by topography, and the easiest and most utilized routes are those of the river valleys. Overland transport is extremely slow and is largely performed by coolie labour Small junks carry goods to the great emporium of western China, Chungking. This treaty port, opened in A.D. 1890, exports silk, tea, rice, cotton goods and tobacco from the Red basin, and hides, wool, timber, skins and medicines from the mountain area west of the Min river. The second category of goods generally comes down the Min river from Chengtu, the capital, a city at the edge of the mountain country, and so admirably placed to receive these commodities from such outpost towns as Tatsienlu and Ya-Chow There are only two good overland roads, firstly, the Great North road from Peking via Sian (Shensi province) to Chengtu, and secondly, the Little North road from Wanhsien to Chengtu. Wanhsien, a small port on the Szechuanese side of the great Yangtze gorges, was opened to foreign trade in A D. 1917, after 15 years' delay. The imports of Szechuan are mainly textiles, dyes, metals, soaps, kerosene, etc, whilst the exports, generally via Chungking and Hankow (Hupeh province) are silk and silk products, wax (from wax insects), tobacco, cotton goods and yarn, tea, wood oil, bristles, salt, sugar, musk and medicinal plants.

See F. von Richtofen, *China*, vol. iii. (Berlin, 1912), L. Richard, *Geogr. de l'Empire de Chine* (Shanghai, 1905).

SZEGED, capital of the county of Csongrád in Hungary and the second town in the country It lies just below the confluence of the Maros and the Tisa. Pop (1920) 119,000. It is modern and well-built, the old town having been almost destroyed by flooding of the Tisa in 1879. In early times it was important because it lay on the salt and timber route from Transylvania to the Adriatic To-day it is essentially a market centre lying at the meeting point of four contrasted regions, viz.—the drift-sand Danube-Tisa zone, the loess-covered Bačka, the garden region of the Körös-Maros interstream area and the cereal belt of the western Banat. It is the seat of a university.

SZÉKESFEHÉRVÁR, a town in Hungary, capital of the county of Fejér, lies in a marshy valley connecting the loess-covered plains of the Danube with the Upper Hungarian Plain (Kis-Alföld) It trades in wine, fruit and horses and has tanneries and shoe factories. The town was the coronation and burial place of the Hungarian kings from the 10th to the 16th century The coronation church was built by St. Stephen, the first king of Hungary and in it were buried 15 kings. At the end of the Turkish occupation, 1543–1686, the church, its tombs and archives

were destroyed. The town is a very old see of a Roman Catholic bishopric. Pop. (1920), 39,109.

SZEKLERS (Magyar Székelv), a people inhabiting the upper valleys of the Mureš and the Olt in eastern Transylvania. They number to-day about 450,000, but are no longer distinguishable from the Magyars, with whom they are closely akin. Their origin has been much debated. According to their own tradition, repeated in Procopius (*de bello Gothico,* iv. 18), they were descended from Attila's Huns, while others have seen in them Black Ugrians. It is, however, now generally accepted that they are true Magyars, transplanted here probably by St. Ladislaus to guard the frontier, their name meaning simply "frontier guards." For their history and bibliography, *see* TRANSYLVANIA.

SZÉLL, KOLOMAN (1845–1915), Hungarian statesman, was born on June 8, 1845. He studied at Budapest and Vienna, and in 1867 became deputy for the district of St. Gotthard. Széll was one of Déak's intimates, whose ward, the daughter of the Hungarian poet Vörösmarty, he had married. In 1875 he was finance minister in the Tisza cabinet, and began the task of restoring the shattered credit of Hungary. In 1878 he concluded with Austria the first economic *Ausgleich.* At that time the single Austrian bank was changed, in conformity with this arrangement, into the dualistic Austro-Hungarian bank, and Széll consolidated the Hungarian *rentes,* and nearly succeeded in balancing the State finances. As he feared that this balance would again be upset by the occupation of Bosnia and Herzegovina, he resigned from the cabinet, incurring thereby the displeasure of the Crown. At the beginning of the eighties Széll founded the Hungarian Mortgage Credit Bank, of which he was governor until the end of his life. He opened entirely new sources of credit for Hungarian agriculture. He declined repeated offers of the portfolio of finance. Széll became prime minister after the fall of Bánffy in February 1899. On the basis of the so-called Széll formula the new *Ausgleich* with Austria until the year 1907 was concluded after long negotiations. He was forced to resign on June 16, 1903. Széll was one of the Liberal seceders in 1904. Under the Coalition cabinet of Wekerle, he was chosen president of the Constitutional Party. He tried continually, but in vain, to bridge the opposition between Tisza and Andrassy. He died on Aug. 16, 1915.

SZILAGYI, DESIDER (1840–1901), Hungarian statesman and jurist, was born at Nagy-Várad (Grosswardein) on April 1, 1840. He studied law at Budapest, Vienna, and in Germany. As head of a section in the Hungarian ministry of justice he went to England to study the conditions of the administration of justice there, and took a conspicuous part in the codification work of the ministry of justice. Deputy in 1871, professor of public law and politics at Budapest university in 1874, he was in 1877 one of the leaders of the opposition, which, however, he left in 1886. In 1887 he was returned to parliament by Pozsony (Pressburg) as an independent member. He became minister of justice in 1889. From this time to 1894 he directed his efforts principally towards a radical reform of the whole administration of the courts. His name is connected with the changes in ecclesiastical legislation made in 1894, notably with article XXXI. of the law of civil marriage, and articles XXXII. and XXXIII. on the religion of the children and on State registration. Szilagyi was president of the house of deputies from 1895 to 1899. He died on July 3, 1901.

See *Szilagyi's Speeches* (4 vols., in Hungarian, ed. Fayer).

SZINYEI-MERSE, PAUL DE (1845–1920), Hungarian painter, was born at Szinyeujfalu and studied art at the Munich Academy. His pictures were characterised by gay and graceful colouring and a lyric view of nature. In 1873 he finished the masterpiece of his life "May Festival." He gave successful exhibitions at Munich (1909), Berlin (1910) and Rome (1911). In 1905 he was appointed director of the Hungarian National Academy of Arts. He died in 1920.

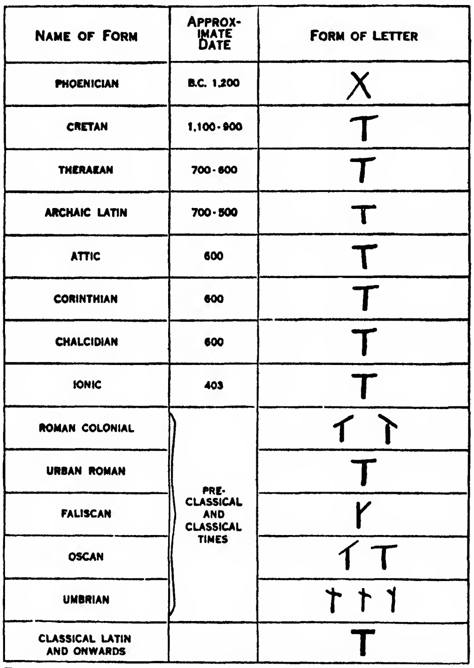
See Béla Lázár, *Paul von Szinyei-Merse* (1911); Alexius Petrovics, *Szinyei Pál* (Arts Lexicon, 1926).

SZOMBATHELY, a town in western Hungary, that has lost, by the rearrangement of the frontier between Austria and Hungary in 1920, a large portion of the area it served as a market. It occupies the site of the Roman capital of Pannonia, *Sabaria Savaria* and many remains of the Roman period have been excavated; some of these are preserved in the museum at Budapest, the remainder in the municipal museum. The town lies in the centre of a rich wine-producing downland and is an important agricultural centre with steam flour and saw mills and factories producing agricultural machinery and textiles in addition to foundries and a state railway workshop. It has been the see of a Roman Catholic bishop since 1777 and possesses a beautiful cathedral and several other ecclesiastical buildings. Pop. (1920) 34,699. About 5 m. S. lies the village of Ják which has an 11th century Dominican convent whose church is reputed to be one of the finest examples of Romanesque architecture in the country.

SZYMANOWSKI, KAROL (1883–), Polish musician, was born at Timoshovka, Russia, of Polish parents, and studied under Sigismund Noskowski at Warsaw. He became one of the leaders in the revival of Polish national music, but his early works owe much to the German tradition. He has written songs, orchestral works and chamber music, but a large proportion of his compositions are for the pianoforte. He has also composed an opera "Hagith" written in 1912 and produced at Warsaw in 1922, which has won many admirers. In the works written after 1914 Szymanowski adopted new and ultra-modern methods.

This letter corresponds to Semitic *tau*, the form of which on the Moabite stone was X. In all Greek alphabets, as well as in the Lydian and the Latin, the form was T Etruscan had a form T, from which probably were derived the Umbrian form Y and the Faliscan † and Y.

Latin cursive gives a form that leans to the right T Carolingian T is based upon uncial T. Generally speaking, in mediaeval mss. the letter did not rise above the line and it is sometimes difficult to distinguish from a minuscule *c* In modern handwriting and printing it is the custom to extend the vertical stroke above the horizontal.



THE DEVELOPMENT OF THE LETTER "T" FROM THE PHOENICIAN THROUGH THE CLASSICAL, DOWN TO THE PRESENT FORM

The sound represented by the letter throughout its history has been the unvoiced dental stop. In English this has become more alveolar than dental, that is to say, it is pronounced by the tongue pressing upon the gums rather than the teeth. Modern unvoiced stops are probably also to be distinguished from the corresponding sounds in ancient Greek by the addition of a slight puff of breath following the sound, thus bringing the sound near to being an aspirate Greek would perhaps have transliterated the English unvoiced stops by the letters θ, ϕ and χ rather than τ, π and κ. This tendency towards aspiration is carried to much farther lengths in the Irish dialects of English. (B F C. A)

TAAFFE, EDUARD FRANZ JOSEPH VON, Count [11th Viscount Taaffe and baron of Ballymote, in the peerage of Ireland] (1833–1895), Austrian statesman, was born at Vienna, Feb. 24, 1833, second son of Count Ludwig Patrick Taaffe (1791–1855), who was minister of justice in 1848 and president of the court of appeal. As a child Taaffe was one of the chosen companions of the young archduke, afterwards emperor, Francis Joseph. In 1852 he entered the public service; in 1867 he was Statthalter of Upper Austria, and minister of the interior in Beust's administration In June he became vice-president of the ministry, and at the end of the year he entered the first ministry of the newly organized Austrian portion of the monarchy For the next three years he took a very important part in the confused political changes, representing essentially the wishes of the emperor. From Sept. 1868 to Jan. 1870 he was president of the cabinet. In 1870 Taaffe, with the other members of the cabinet who advocated concessions to federalism, resigned. He returned to office in April, resigned once more, and became Statthalter of Tirol.

On the breakdown of the Liberal Government in 1879 he was again called to office, becoming minister-president in July, and held office until July 1893, when he was defeated on a proposal for the extension of the franchise and resigned, dying at Ellerschau, Bohemia, on Nov. 29, 1895. For the history of Taaffe's administration, *see* Austria Essentially an opportunist, he maintained office for many years by an unprecedented employment of the principle *divide et impera* Usually resting on the Slavs and clericals, he was accused by the German Liberals of ruining Austria; but he united a deep devotion to the emperor with a singular gift for managing men and at least prolonged the life of an impossible system.

By the death of his elder brother Charles (1823–1873), a colonel in the Austrian army, Taaffe succeeded to the Austrian and Irish titles. He married in 1862 Countess Irma Tsaky, by whom he left four daughters and one son, Henry

See Wurzbach, *Biographisches Lexicon Oesterreichs Memoirs of the Family of Taaffe* (Vienna, 1856), privately printed, and Taaffe's *Political Correspondence* issued after his death.

TA'AISHA: *see* Bakkara

TAAL, a municipality (with administration centre and 47 *barrios* or districts), of the province of Batangas, Luzon, Philippine Islands, on the Pansipit river, opposite Lemery, with which it is connected by a bridge It is about 50 m south of Manila and near to Lake Taal Pop (1918), 21,155 Extensive agricultural lands in the vicinity produce rice, corn, sugar and other products. The breeding of horses and cattle and fishing are also important industries. On an island in Lake Taal is the volcano of Taal which has had numerous violent eruptions—the last in Jan 1911 Baskets, mats, harness, shoes and slippers, bolos and embroidery are made in considerable quantities. In 1918, Taal had 13 manufacturing establishments, 3 rice mills, 31 sugar mills and 941 household industry establishments. The language is Tagalog.

TABACO, a municipality (with administration centre and 45 *barrios* or districts) and port of entry of the province of Albay, Luzon, Philippine Islands, on Tabaco bay, a protected harbour about 20 m. north of Albay, the provincial capital, with which it is connected by the railway. Pop. (1918), 24,812. Abacá is the principal agricultural product Cloths, baskets and mats are woven by the women. Tabaco has considerable commercial importance. In 1918, it had 16 manufacturing establishments and 664 household industry establishments. There were eight public schools. The language is Bikol.

ṬABARĪ [Abū Ja'far Mahommed ibn Jarīr ut-Ṭabarī] (838–923), Arabian historian and theologian, was born at Amol in Tabaristan and studied at Rei (Rai), Baghdad, and in Syria and Egypt. Cast upon his own resources after his father's death, he was appointed tutor to the son of the vizier 'Ubaidallāh ibn Yaḥyā. He journeyed to Egypt, but soon returned to Baghdad, where he remained as a teacher of tradition and law until his

death. A Shāfi'ite in law, he claimed the right to criticize all schools, and ended by establishing a school of his own, in which he incurred the wrath of the Hanbalites.

Two of his works are very extensive. The one is the *Tārīkh ur-Rusul wal-Mulūk* (History of the Prophets and Kings), generally known as the *Annals*. (*Cf.* ARABIA, *Literature*, "History.") This is a history from the Creation to A.D. 915, and is renowned for its detail and accuracy. It has been published under the editorship of M. J. de Goeje (Leyden, 1879–1901). His second great work was the commentary on the Koran, which was marked by the same fullness of detail as the *Annals*. It has been published in thirty vols. (with extra index volume) at Cairo, 1902–1903.

TABASCO, a state of Mexico. Area 9,783 sq. miles. Pop. (1921) 210,437. The surface is generally low and flat, largely covered with lagoons, watercourses and swamps. In the south and south-east there is an area belonging to the rough higher formation of Chiapas. Dense forests cover the whole region, and there are valuable fine woods and dye-woods. There are several large lagoons on the coast, two of which are called Santa Ana and Tupilco bays. Two large rivers, the Grijalva and Usumacinta, traverse its territory. The Grijalva, also called Tabasco, the upper course of which is known as the Chiapas, is navigable for 93 miles. The Usumacinta forms the boundary between Guatemala and Chiapas until the frontier of Tabasco is reached, where its north-west course turns to the north and then north-west to a junction with the Grijalva—the two rivers having a common outlet. The Usumacinta, including its head streams, is about 500 m. long; excluding them about 330 m.; for about 270 m. it is navigable and for about 180 m. it is navigable by large steamers. There are no railways and few good roads, and these rivers and the navigable channels of the Cuxcuchopa, Soledad, Cocohital, Tular and Tortuguero are the principal practical thoroughfares in the State. The capital is Villahermosa (pop., 1921, 15,819), on the Grijalva river. The next most important town is Frontera, a port 3 m. within the mouth of the Grijalva.

TABERNACLE, the name given in the English Bible to the portable sanctuary, erected by Moses in the wilderness as the place of worship of the Hebrew tribes (Exod. xxv. *sqq.*). It stood within a rectangular court, measuring 100 cubits by 50, say 150 feet by 75, which formed the centre of the camp in the wilderness. Of the two equal squares into which the court may be divided, the more easterly was that in which the worshippers assembled. In the centre of this square stood the altar of burnt-offering, a hollow chest of acacia wood overlaid with bronze. In the western square stood the tabernacle itself. The essential part of the structure was that termed in the original the *mishkān*, *i.e.*, dwelling. It was formed of ten curtains, in two sets of five, of the finest linen with inwoven coloured figures of cherubim spread over a series of open frames of acacia wood overlaid with gold, each 10 cubits in height by 1½ in breadth. These frames, 48 in all, were so arranged as to form the southern, western and northern sides of a rectangular structure, 30 cubits in length and 10 in breadth and height, whose eastern end, forming the entrance, was closed by a special portière suspended from five pillars. The dwelling was divided into two parts by a second hanging, the "veil," 10 cubits from the western end. These two parts were termed respectively the holy place, and the most holy place or "holy of holies." Within the latter stood the ark of God, in which were deposited the two stone tables of the decalogue or "testimony." On the ark lay a solid slab of the finest gold, the propitiatory or mercy-seat, from which rose the figures of two golden cherubim, forming the innermost shrine of the wilderness sanctuary, the earthly throne of the God of heaven.

The furniture of the holy place consisted of the table of shew-bread, the altar of incense—both, like the ark, of acacia wood overlaid with gold—and the golden "candlestick," or seven-branched lamp-stand. As a protection the delicate and artistic curtains of the dwelling were covered by two similar sets of goats'-hair curtains; these, in their turn, were protected by a double covering, the one of rams' skins dyed red, the other made of the skins of a Red Sea mammal, probably the dugong (Exod. xxvi. 14).

The aim of the "priestly" writers, to whom we owe this conception of the tabernacle, was to provide a sanctuary and a ritual worthy of the higher conceptions of the Deity, which had grown up as the fruit of the discipline of the exile. The thought of the almost unapproachable holiness of the Deity underlies not only the gradation of the parts of the tabernacle—court, holy place and holy of holies, each marked by an ascending degree of sanctity—but also the careful gradation of the materials employed in its construction. The whole is to be regarded as the expression of a religious ideal. Building on the traditions of the simple Mosaic "tent of meeting," the priestly idealists followed the example of Ezekiel, and elaborated a sanctuary to serve as the model for the worship of the theocratic community of the future. "Let them make me a sanctuary, that I may dwell among them" (Exod. xxv. 8).

BIBLIOGRAPHY.—*See* "Tabernacle" by Kennedy in Hastings' *D.B.*, with which may be compared the corresponding articles in the *Ency. Bib.* by Benzinger, and in the *Jewish Encycl.* by König; also the commentaries on Exodus. (A. R. S. K.)

In architecture, the term loosely expresses a niche for a statue, with a canopy (*q.v.*) over it, especially in the mediaeval styles. When niches are arranged in vertical rows, with the canopy over one statue acting as the pedestal for the one above, the whole composition is often termed tabernacle work. The same term is also used for any richly decorated tabernacle or canopy-like forms, whether true tabernacles or not.

TABERNACLES, FEAST OF. A famous Jewish festival which commences on 15 Tishri (five days after the Day of Atonement), and lasts seven days. Of these the first two (Tishri 15 and 16) are full festival days, the last five (Tishri 17–21) half-holidays. The "eighth day" Festival (Shemini Aisereth), which like other festival days is doubled (Tishri 22 and 23; the second day in this case is called *Simchath Torah*), closes the celebration. The whole nine days bear one descriptive designation, "season of our rejoicing." The festival is one of venerable antiquity. Its observance is commanded in the Mosaic Law (Lev. xxiii. 34), and its purpose is there explained as to commemorate the way in which the Israelites dwelt in booths (*sukkoth*) in the wilderness.

Every Jew who owns a court or garden is required to erect a booth or something more or less equivalent, and to dwell in it—or at least have meals in it—while the feast lasts. In order that the character of the original booth may as far as possible be retained, the modern counterpart is very lightly constructed. It "must not be covered with fixed boards and beams or with canvas, but with detached branches of trees, plants, flowers and leaves, in such a manner that the covering is not quite impenetrable to wind and rain or starlight" (Friedlander). The booths are required to be made during the days that intervene between the Day of Atonement and the Feast itself; they are adorned with garlands, flowers, and the like; often the text "Ye shall dwell in booths seven days" (Lev. xxiii. 42), is displayed in a prominent place within the booth. On the eve of the Feast the members of the household attend Synagogue, and on returning assemble in their booth and partake of a meal. On this evening (the first of the Feast) the meal (as in the case of the weekly Sabbath on Friday evening) is preceded by Qiddush or the solemn sanctification, first over a cup of wine which is then handed round, all drinking of it, and then over two wheaten loaves, specially baked and placed on the table covered with a cloth; these the head of the family then proceeds to cut into pieces, which are distributed to and eaten by all present. A special blessing—which is repeated before every meal during the seven days—follows ("Blessed art Thou, O Lord . . . Who hast commanded us to dwell in a booth"). At the conclusion of the meal, and on leaving the booth the following prayer is said by the head of the household:

> May it please Thee, O Lord my God, and God of my fathers, that in like manner as I have this time obeyed Thy command and have been sitting in the booth, so in the coming year I may be counted worthy to sit in the booth of Leviatham.

It should be observed that the Leviatham plays a prominent part in haggadic legend, especially in connection with the Messianic time. The monster is to be killed and the flesh is to furnish food for the righteous (at the Messianic banquet). From the

hide tents will be made by God for the pious of the first rank. This last feature will explain the allusion in the text of the prayer.

On the occasion of the ceremony, the Synagogue is decorated with plants and fruits and certain ceremonies are carried out, viz., palm-branch processions culminating on the seventh day at the *Musaf* or additional service. For further details *see* Oesterley and G. H. Box, *Religion and Worship of the Synagogue* (2nd. ed. 1911). (G. H. B.)

TABLE (Lat. *tabula*), in furniture, a flat, oblong slab supported upon legs or pillars. Of the many kinds of tables according to their uses, the following are outstanding as pieces of furniture and in artistic possibilities: (1) artist's table, (2) billiard table (*q.v.*), (3) breakfast table, (4) card table, (5) china table, (6) console table, (7) dining table, (8) dressing table, (9) library table, (10) side table, (11) sofa table, (12) tea table, (13) wine table, (14) work table, (15) writing table. The table was known, in a small and rudimentary form, to the Egyptians, who used wood for its construction; the Assyrians certainly employed metal and possibly other materials in its manufacture. Grecian tables were also often of metal, with three or four legs and of considerable variety of form; they were small and low. By Roman times the table had apparently become somewhat more common. The favourite form was the tripod, but one and four legs were also used. (*See* Plate I., BRONZE, GREEK AND ROMAN.) Already the shape varied considerably, and in addition to wood, there were tables of marble, ivory, bronze and the precious metals The more costly examples were carved, inlaid or otherwise ornamented; cedar and the finely marked or grained woods generally were much sought after. As in Greece the tables were low; they were intended for reclining, rather than sitting; their legs were those of wild beasts, or were formed of sphinxes, termini and other figures. Some of those which remain are of extreme grace and most delicate workmanship; to them the Empire style is enormously indebted. In antiquity tables of any kind can only have been the appanage of the rich. In the early middle ages, although there was variety of form—the circular, semi-circular, oval and oblong were all in use—tables appear, save in rare instances, to have been portable and supported upon trestles fixed or folding, which were cleared out of the way at the end of a meal. The custom of serving dinner at several small tables, which is often supposed to be a very modern refinement, was certainly followed in the French châteaux, and probably also in the English castles, as early as the 13th century. For persons of high degree, fixed tables were reserved. Even at a period when domestic furniture was of a very primitive character and few modern conveniences had been evolved, costly tables were by no means unknown—some dim traditions of Rome's refinements must necessarily have filtered through the centuries. Thus Charlemagne possessed three tables of silver and one of gold—no doubt they were of wood covered with plates of the precious metals. Before the 16th century the number of tables properly so called was small; hence very few of earlier date than the middle of that century have come down to us. In the chapter-house of Salisbury cathedral is a restored 13th century example which stands practically alone. In point of age it is most nearly approached by the famous pair of trestle tables in the great hall at Penshurst.

ENGLISH CHIPPENDALE TRIPOD TABLE WITH TILT TOP, 1760–1770

When the table became a fixed and permanent piece of furniture the word "board," which had long connoted it, fell into disuse save in an allusive sense, and its place was taken by such phrases as "joyned table" and "framed table"—that is, jointed or framed together by a joiner; sometimes people spoke of a "standing" or "dormant" table. They were most frequently oblong, some 2 ft. or 2 ft. 6 in. wide, and the guests sat with their backs to the wall, the other side of the table being left free for service. Sometimes they were used as side-tables, or furnished with a cupboard beneath the board; they were supported on quadrangular legs or massive ends and feet, full of Gothic feeling, and were several inches higher than the dining-table of the 20th century. Heavy stretchers or foot-rails were fixed close to the floor—for the avoidance, no doubt, of draughts Oak was the usual material, but elm, cherry and other woods were sometimes used. Soon the legs became bulbous, and were godrooned or otherwise ornamented, and the frame began to be carved. The introduction, before the 16th century closed, of the "drawing table" marked the rapidity with which this piece of furniture was developed. This was the forerunner of the "extending dining table." Of the three leaves of which these tables were composed two were below the other; they drew out and were supported by brackets, while the slab proper dropped to the same level. Somewhat later legs became excessively bulbous; this ugly form gave place soon after the middle of the 17th century to baluster-shaped legs. Hitherto tables had, generally speaking, been large and massive—little in the nature of what is now called the "occasional table" seems to have been provided until some years after the Restoration. About that time small tables of varying sizes and shapes, but still of substantial weight, began to be made; many of them were flap-tables, which took up little room when they were not in use. These, however, had been known at an earlier date. Charles II. had not long been on the throne when the idea of the flap-table was amplified in a peculiarly graceful fashion. Two flaps were provided instead of one, the result being the rather large oval table of the "gate-leg" variety that has remained in use ever since, in which the open "gate" supports the flap. (*See* INTERIOR DECORATION; *English Furniture*, Plate I.) Towards the end of the reign tables began to have the graceful twisted legs joined to the flat serpentine stretchers, which produced, almost for the first time in English furniture, a sense of lightness and gaiety. The walnut tables of the end of the Stuart period were often inlaid with marquetry of great excellence. The number and variety of the tables in well-to-do households were now increasing rapidly, and the console-table was imported from the Continent contemporaneously with the common use of the mahogany side-table.

As mahogany came into general use, about the beginning of the second quarter of the 18th century, an enormous number of card-tables were made with plain or cabriole legs and spade or claw and ball feet, often with lions' heads carved upon the knees; the top folded up to half its size when open The Chippendale school introduced small tables with carved openwork "galleries" round the edges (to protect china and other small objects), and clustered legs; Gothic forms and Chinese frets were for a time fashionable. Later in this century, so prolific in new forms of furniture, tables were frequently made of rosewood and satinwood; side-tables, often highly elaborate, adorned with swags and festoons and other classical motives, supported by termini or richly carved legs, were gilded and topped with marble slabs or inlaid wood. (*See* INTERIOR DECORATION; *English Furniture*, Plate III.) The Pembroke table, of oblong form, with two semi-circular or oblong leaves, with edgings of marquetry, was a characteristic feature of late 18th century English furniture, and still retains its popularity. During the Empire period the taper was replaced by the round leg, rosewood grew commoner, and brass mountings became the rule. (For further illustrations *see* INTERIOR DECORATION; *European; Early American; Modern;* also, MODERN TENDENCIES IN APPLIED ARTS.)

TABLE MOUNTAIN (Dutch *Tafelberg*), a name frequently given in South Africa to flat-topped hills and mountains, which are a characteristic feature of the scenery. Occasionally such hills are called *plat, i.e.,* flat, *bergen.* Specifically Table Mountain is the mountain, which rises from the shores of Table bay, Cape Town lying at its seaward base and on its lower slopes. The mountain forms the northern end of a range of hills which terminates southward in the Cape of Good Hope. It is formed of gently inclined sandstones and quartzites of the Table Mountain Sandstone series, resting unconformably on granites, which are intruded into shales of the Malmesbury Series. The sandstones descend toward sea-level on the shores of False bay,

TYPES OF TABLES

1. Table of Egyptian wood, XVII.–XVIII. Dynasty, Drah abu'l nagga, Thebes
2. Writing table of carved wood, English, late 16th century
3. Gate-leg table, American walnut, 1675–1700
4. Spanish table, 17th century
5. Carved Italian table of the 16th century
6. American oval butterfly table of walnut, 17th century
7. English draw table, closed, 16th century
8. Gilded wood French side table, Louis XVI. (18th cent.)
9. Lacquered Chinese table
10. Writing table with mounts of gilt bronze
11. Table in the modern mode

but are too high to be accessible as building stone for Cape Town. The northern face of the mountain, overlooking Table bay, extends like a great wall some two miles in length, and rises precipitously to a height of over 3,500 feet. The face is scored with ravines, a particularly deep cleft, known as The Gorge, affording the shortest means of access to the summit. East and west of the mountain and a little in advance of it are lesser hills, the Devil's Peak (3,300 ft.) being to the east and Lion's Head (2,100 ft.) to the west. Lion's Head ends seaward in Signal hill (1,100 ft.). The western side of Table Mountain faces the Atlantic, and forms an escarpment, with a broken sky line, known as The Twelve Apostles: to the south Hout's Bay Nek connects it with the remainder of the range; on the east the mountain overlooks the Cape Flats. On this side its slopes are less steep, and at its foot are Rondebosch, Newlands, Wynberg, and other residential suburbs of Cape Town. The ascent of the mountain from Wynberg by Hout's Bay Nek is practicable for horses. The surface of the summit is broken into small valleys and hills, and is covered with luxuriant vegetation, its flora including the superb orchid *Disa grandiflora* and the well-known silver tree. The Kasteel-Berg (Castle Mount), a northern buttress of the mountain, has its own peculiar flora.

The south-east winds which sweep over Table Mountain frequently cause the phenomenon known as "The Table-cloth." The summit of the mountain is then covered by a whitish-grey cloud, which is being constantly forced down the northern face towards Cape Town, but never reaches the lower slopes. The clouds (not always caused by the south-easter) form very suddenly, and the weather on the mountain is exceedingly changeable. The rainfall on the summit is heavy, 72·14 in. a year being the average of twelve years' observations. This compares with an average of 54·63 in. at Bishop's Court, Newlands, at the foot of the mountain on the east, and with 25·43 in. at Cape Town at the northern foot of the mountain. The relative luxuriance of the vegetation on the upper part of the mountain, compared with that of its lower slopes, is due not only to the rainfall, but to the moisture condensed from clouds. (*See* also CAPE TOWN.)

TABLES, MATHEMATICAL: *see* MATHEMATICAL TABLES.

TABLINUM, in architecture, one of the most important rooms of a Roman house, usually of large size, opening off the atrium (*q.v.*), in the centre of the side opposite the entrance. At its rear there was frequently a large window looking out on the peristyle (*q.v.*) or colonnaded inner court. It was frequently decorated with busts or pictures of the family ancestors, and took the place of the modern, formal drawing room.

TABOR, a small town in Bohemia, Czechoslovakia, on the Luznice, a tributary of the Vltava, is mainly of historical importance since it was founded in 1420 by the more advanced Hussites, who came to be known as Taborites. In site and build it indicates its original purpose. Standing on the summit of an isolated hill, separated from the surrounding country by the Luznice and protected by marshes, the market place in the centre of the town is approached by very narrow streets to render the approach difficult in time of war. In this market place stands a statue of Žižka, one of the most famous Hussite leaders. Here also are the early 16th century diaconal church and the town hall with its museum of Hussite memorials. The district around Tabor is not particularly fertile, producing mainly the hardier cereals and potatoes. Pop. (1921) 12,561.

TABORA, a town of East Africa, Tanganyika Territory, in the Unyamwezi country (known officially as the Tabora district). Pop. (1921) about 25,000, including 150 Europeans and 1,200 Asiatics. Tabora is on the railway (completed in 1914) from Dar-es-Salaam to Kigoma, on Lake Tanganyika, being 530 m. from the ocean and 212 m. from the lake port. Another railway, 238 m. long (completed in 1928) links Tabora to Mwanga, on Lake Victoria. Tabora has several fine buildings, including government offices, churches, hospitals and schools. A Government school for the sons of chiefs combines farm work with literary teaching. There are large railway workshops and an aerodrome (first used in 1920, when aeroplanes arrived from Cairo).

The modern town was founded by Zanzibari Arabs, about 1820, close by the *boma* of a chief of the Nyamwezi. Its central position and good water supply made it an important trading centre and a place of strategic importance. The Germans built a strong fort here. During the World War it was captured by the Belgian Congo troops (Sept. 1916), and later passed to British administration. (*See* UNYAMWEZI and TANGANYIKA TERRITORY.)

TABRIZ, chief town of the province of Azerbaijan and second largest city of Persia, lies in the valley of the Azi Chai (the Bitter river which flows into Lake Urmia) at an elevation of 4,400 ft., in 38° 4′ N., 46° 18′ E., and 320 m. N.W. of Tehran. Overlooking the valley on the south rises the volcanic cone of Sahand (12,000 feet). The city was reported in 1880 to contain 318 mosques, 100 public baths, 166 caravanserais and some 26,000 houses; but in reality there is little of striking character to be seen except the bazaars and the Qabud Masjid, or Blue Mosque, with its stately façade of blue faïence, close to the gate leading to the Tehran road. The Ark, or Castle, a lofty structure dating from the middle ages, is a ruin. Two gates are memorials from 1882, when the Kurds under Shaikh Ubaid Allah attacked Tabriz and conquered Urmia. For the rest, the city consists of an interminable collection of yellowish-grey, uniform houses intersected by a labyrinth of crooked and narrow lanes, but, since the new régime in Persia, some streets have been widened. On the outskirts are beautiful gardens and the more modern country houses of the wealthy classes. The maximum summer temperature is 100° in August, and the minimum 6°; rainfall about 9 in.

Tabriz figures prominently in the chronicles of almost every traveller of note in Persia, in ancient and mediaeval times, from Marco Polo to Chardin and Tavernier. It was for a long period the great emporium of European trade with Persia, situated as it was on the main route from Trebizond and Erzerum; but since the opening of the Suez Canal drew to itself the trade of the southern half of Persia, and the railway through the Caucasus gave greater transport facilities on the Caspian Sea diverting the trade to Astara and Pahlevi, it has lost some of its activity. The difficulty and insecurity of the Trebizond-Tabriz roads and the recent rehabilitation of the 'Iraq have still further diverted much commerce by way of Baghdad. It is nevertheless a principal trade centre and point of local distribution and collection for N.W. Persia. The railway from Tabriz to Julfa (80 m.), built by the Russians in 1916 and transferred to Persia in 1921, connects with the Caucasian system and though in 1928 this line was in bad repair and lacked rolling stock there were signs of improved traffic. A constructed road suitable for heavy motor traffic runs parallel to the railway and continues to Khoi. From Tabriz to Tehran, via Kazvin, and to Astara on the Caspian Sea, via Ardabil, are unmetalled roads, but passable for motors.

Tabriz is the centre of the dried fruit industry of Azerbaijan, as well as the headquarters of an important rug industry. A match factory was working in 1927. There is a branch of the Imperial Bank of Persia and a local telephone service. The total value of trade passing through Tabriz in 1925–26 was 111,480,413 krans (£ St. = 45 krans), of which 38,476,072 krans represented exports, chiefly carpets (29,337,601 krans), fruits (3,781,512 krans) and hides and skins. The chief imports were textiles, sugar and tea.

Tabriz (ancient Tauris) was probably an old city when it became the capital of Tiridates III., king of Armenia, in A.D. 297. In 858, in the reign of the tenth Abbasid Caliph, it was almost destroyed by earthquake, and again in 1041. In 1392, Timur took and sacked the city and, later, it fell under the sway of certain Turkman princes, from whom, in 1500, Ismail, first of the Safavis, took it; but it remained under Persia only till 1522 and then fell under Turkish rule. In 1618 Shah Abbas I. won it back to Persia. In 1721 the town was again in great part destroyed by earthquake and again passed, after a sanguinary struggle, under the Turks who held it until 1730, when it was retaken by Nadir Shah. Tabriz remained under the Persians until it was taken by the Russians in 1827, to be restored to Persia in 1828. Since 1905 it has been the capital of the heir-apparent. In 1908, the revolution against the Shah started at Tabriz and the arrival of Russian troops in 1909—nominally to save Russian subjects from famine

—marked the commencement of a Russian occupation of this as well as other Persian towns. Tabriz became involved in the World War owing to Turko-Russian conflicts and was occupied by the Russians in 1915 and again by the Turks for a short period in 1918 These alternate occupations thoroughly disorganized the civil administration and economical conditions of the province of Azerbaijan from which, in 1928, it had scarcely recovered.

TABU. Tabu, one of the few savage words that have struck root in the English language, is of Polynesian origin and has dialectical forms (*tapu, kapu, tambu*) in Polynesia and Melanesia; but the form *tabu* (or *taboo*) is the one which has become popularized, because it was as *tabu* that Capt. Cook first discovered the notion and its associated customs at Tonga in 1771.

I. MEANING OF TABU

Literally an adjective, meaning "marked off" (perhaps from the Polynesian *ta*=mark, *pu*=exceedingly), tabu implies that certain persons or things are unsafe for casual contact or use in ordinary life, "not to be lightly approached" (Codrington, *The Melanesians*, p 188) because of supernatural penalties which would thereby be incurred. There is always some occult, magico-religious significance present. Another Polynesian word, *mana* (*q v.*), expresses conveniently its positive aspect. Mana implies the mysteriously-efficient, transferable force recognized in all remarkable, impressive, wonder-working things as well as in striking human personalities. "Negatively, the supernatural is *tabu*, not to be lightly approached because (positively) it is *mana*—instinct with a power above the ordinary." Thus, for the Ila-speaking peoples of northern Rhodesia, we are told, vaguely-defined forces pervade all things, neutral in themselves, but available for those who have "the secret of manipulation." These forces, however, "are dangerous things to interfere with. They are *tonda* (tabu). For an ordinary person, under ordinary circumstances, to interfere with them is forbidden; it is dangerous to himself and the community. By saying certain things, doing certain actions and eating certain foods, he may liberate these energies with fatal results to himself and his neighbours. Persons in certain conditions and things put to certain uses, come into intimate contact with these forces and are therefore *tonda*." (Smith and Dale, *Ila-speaking Peoples of N. Rhodesia*, ii. 83.)

Tabu may be either (1) inherent or (2) imposed.

(1.) **Inherent Tabu.**—Some things or conditions are intrinsically tabu, and infringement of their character brings its own penalty without external aid Such inherent tabus are those associated permanently with women, the sick, the dead, strangers or temporarily with women in childbirth or warriors on campaign. Here inherent energy is discharged on all who break the tabu.

(2.) **Imposed Tabu.**—A common thing may become tabu through the action of a god, priest, king or chief, and the sanction of the restriction is his own power for avenging its violation. Thus, when Cook wanted to set up an observatory in the Sandwich islands, the priests tabued the place for him by setting up wands. Persons and things, places and times could be tabued. The power of imposing a tabu was a characteristically Polynesian prerogative, bound up with the theocratic powers of a prince or noble, which probably attained the highest development in New Zealand. The noble or chief, partaking of the divine essence of which he was the incarnation, was able to communicate his contagious holiness so that the objects in question could not be appropriated by anyone but a superior in rank. He might stop traffic on a river or cause great inconvenience to his people by tabuing a forest. This was generally done by putting up a pole with a bunch of rags or leaves or by erecting some corresponding notice-board. On the other hand, just as the priest or chief could impose the tabu, he could also remove it. Thus, at Hawaii in 1819, King Rihoriho at one stroke abrogated the laws of tabu, though only to make way for *le tabu*, the British Sunday.

However, these two aspects of tabu are considerably involved, for religion makes common cause with law and government, resulting in a theocratic system of controls, spiritual injunction backed by temporal power.

(3.) **Derivative Tabus.**—A third class of tabus arises from the contagiousness of tabu. It is transmitted by contact and the person or thing thus tabued becomes a new source of infection. Sometimes the infection may be removed by ritual means, such as an ablution. Sometimes it is too deeply ingrained to be removed. To discriminate between "things tabu," the primary sources of such contagion and "things tabued," in which tabu infection is derivative, is not always easy, since tabus as primarily matters of custom form part of the social inheritance. Thus, the clothing and discarded food of the king derive the tabu quality from his person. Further, not only what he touches, but what he sees also becomes tabu.

The Ambivalence of Tabu.—Of extreme importance in the study of tabu is its ambivalent character *Either* that which is tabu is holy and to be feared as the seat of mystic, supernatural power, and therefore to be avoided lest harm befall from contact with it, or lest it be defiled by human touch and its divine essence be affected, *or* the object is unclean and therefore tabu lest it infect man with its own evil nature. Thus from this single root sprang not only uncleanness but also holiness.

II. MAJOR TABUS

(a) **Tabus on Priests, Kings, Chiefs, etc.**—Sir James Frazer has collected in the *Golden Bough* evidence of the tabus with which the semi-divine potentates, chiefs and priest-kings of primitive communities are surrounded. Thus, at Shark Point, West Africa, the king lives alone in a wood. He may never leave his house; he may not touch a woman; on no account may he quit his royal chair, even to sleep, for in that case the wind would die down and all navigation would stop. The supreme ruler at Congo is regarded as a god on earth. No subject may taste of any crop until the first-fruits have been offered to his majesty. When he leaves his residence, to visit other parts of his territory, all married persons are under obligation to observe the strictest laws of continence, any violation of which would prove immediately fatal to him. Were he to die a natural death, the world would be annihilated "Among the Todas of southern India, the holy milkman who acts as priest of the sacred dairy, is subject to a variety of burdensome restrictions during the whole time of his incumbency, which may last many years. Thus, he must live at the sacred dairy and may never visit his home or any ordinary village; he must be celibate; if he is married, he must leave his wife. On no account may an ordinary person touch the holy milkman or the holy dairy. such a touch would so defile his holiness that he would forfeit his office. . . . Further, the holy milkman never cuts his hair or pares his nails so long as he holds office· he never crosses a river by a bridge, but wades through a ford and only certain fords"

The sacred person must be guarded from harm without, but others must be protected also from hurt from him as a centre of contagion. Thus in a higher civilization, should anyone wear the mikado's clothes without his knowledge, he would have swellings all over his body. The touch of the king may remove the tabu caused by his own contagion. The Tongans were subject to a form of scrofula, which they often attributed to having inadvertently touched the chief or his belongings, and the touch or pressure of the chief's foot was sought as a cure for the malady. The sick man "sat down before the chief, and taking the chief's foot pressed it against his own stomach, that the food in his belly might not injure him, and that he might not swell up and die." It is possible that scrofula may have obtained its name of "king's evil" in 17th century England from the belief that it was caused, as well as cured, by contact with the majesty of kings.

In short, "the chief has mana, and is therefore feared. Men do not dread contact with the king lest they become kingly, but lest they be blasted by the superman's supermanliness."

(b) **Tabus on Women.**—In the "classic, well nigh universal" major tabu of the "woman shunned," the ambivalent nature of the emotion underlying tabu is especially seen. Full of mystery,

especially at certain periods of her life, she is now worshipped as a goddess, now dreaded as a witch. The power to bring forth children indicates the possession of mana: hence the almost universal avoidance of the pregnant woman. Of the aborigines of the Amazon, it was said: "They believe that if a woman during her pregnancy eats of the meat, any other animal partaking of it will suffer; if a domestic animal or tame bird, it will die; if a dog, it will be for the future incapable of hunting, and even a man will be unable to shoot that kind of game for the future." In Fiji, a pregnant wife may not wait upon her husband. Among the Australian aborigines, women are secluded at childbirth and menstruation and all vessels used by them during this seclusion are burnt. Their very glance is poison and in some places girls, when tabu, are made to wear broad-brimmed hats lest their glance should infect the sun. Violation of the tabu on women may result in "sure death" through fright, as in the case of the Australian black fellow who, when he discovered that his wife had lain on his blanket during her tabued period, wholly succumbed to terror and died within a fortnight.

(c) **Tabus Between Relations.**—The Kirghiz woman does not look upon the face of her husband's father or elder kinsman and must never utter their names, even if they contain names of common objects but must use paraphrases, and, in describing a wolf carrying off a lamb through the rushes, would say "Look yonder, the howling one is carrying off the bleating one's young through the rustling ones on the other side of the glistening one." There is no suggestion of hostility between the tabued relatives, the stress being entirely upon the mutual respect shown.

This avoidance between relatives of opposite sexes has been closely associated with the general tabu on women. No doubt a mutual shyness between the sexes underlies these avoidances which are strongly reinforced by an admixture of the fears involved in the woman-tabu. But the tabu applies to both sexes. Woman is not avoided *as woman.* Other sentiments, especially the horror of incest, are involved.

(d) **Tabu on Strangers.**—The almost universal tabu on strangers is evidence of the fear of the unknown. "To guard against the baneful influence exerted voluntarily or involuntarily by strangers," says Frazer, "is an elementary dictate of savage prudence," but they may be admitted after a purificatory ceremony, for nearly all tabus may be neutralized by some ceremonial device. Westermarck has shown how both the tabu on strangers and the widely-spread practice of hospitality can ultimately be traced to the same root. The stranger is dangerous; it is therefore necessary to secure his good will at once. For the blessing of the stranger within the gates has exceptional power; his blessing is sought as urgently as his curse is feared.

(e) **"Sympathetic" Tabus.**—Much of the attention of the savage is directed to the food he eats. The belief that the qualities of the eaten pass into the eater, is an explanation of the food tabus and prejudices of savage peoples. Thus the hunter will not eat the heart of the deer he has killed lest he become timid like that animal, while to eat the heart of a lion would be to gain all the fierce courage of that beast. Such examples, however, do not warrant the definition of tabu as "negative magic," failing to cover the characteristics of many well-known tabus. "Sympathetic tabus" many of them certainly are up to a point, as are also the tabus on knots at childbirth, which must be observed lest delivery be impeded. But if tabu were a form of magic, the penalty for its infraction would be definite and measurable; whereas the distinguishing characteristic of tabu everywhere is the "infinite *plus* of awfulness" always accompanying its violation. There may be certain definite results, such as prescribed punishment for violations or social "growlings" showing the opposition of public opinion, to which the savage is at least as keenly sensitive as civilized man. But the "infinite *plus,*" always attached to the violation of tabu puts it into the realm of mystical, immeasurable dread. The threat is the more dire, because left to the imagination. "Do not meddle, or, if you do . . . !"

III. TABU AS A FACTOR IN MORAL TRAINING

While excessive development of tabus in any given society forms an insuperable barrier to progress, the code of tabu has an obvious ethical value. It helps men to realize that they are under obligation to the community of which they are a part. Young people begin to learn this lesson of social life at the very beginning of puberty and incorporation into the life of the tribe. The tabus and prohibitions with which they are surrounded, touch every phase of social, family and individual life from childbirth to burial.

Some have held that tabu is the *origin* of all ethics and morality. It is true that tabu has legalized and strengthened morality and, when tabus come to be regarded as the will of the gods, a rational element is introduced and the fear element, which now contains wonder and humility, is ready for transmutation into the loving reverence of the higher religions.

TABULARIUM, the technical name of the record office or national archives building of ancient Rome, which dominates the west end of the Forum. It is built along the side of the Capitoline hill and was bordered, on the side toward the Forum, by two storeys of long arcades, the lower decorated with engaged Doric columns, and the upper with engaged Ionic columns. Each bay of the arcade is covered by a square, cloistered or four-sided vault. The tabularium is ascribed to Quintus Lutatius Catulus (*c.* 78 B.C.). It thus offers one of the earliest Roman examples of the use of engaged columns in connection with an arcade.

TABULATING MACHINES are mechanisms controlled by perforated cards which are used as mechanical aids to business methods. The first modern device of this class was designed for the automatic tallying or tabulation of statistics; but with extensive development modern tabulating machines are capable of automatically figuring and printing a report based on the information given to it in the form of perforations in cards or tape. Soon after the introduction of the Jacquard loom, in which the hooks lifting the warp threads were controlled by cards perforated to the desired pattern, Charles Babbage applied the principle to a calculating mechanism. Between 1834–54 he designed and partly built an "analytic engine" in which both the amount to be operated upon and the nature of the operation were entered by perforated cards. His machine was never completed. Development of the modern tabulating machine was accomplished by H. Hollerith.

Hollerith's first contribution was a means of tallying census returns through electrical reading of the data punched on cards and accumulating the totals in separate registers. The system was successfully used in the U.S. Census of 1890. During the next decade notable improvements were made including automatic feeding of the cards under brushes for reading and a machine for sorting the cards rapidly into desired groupings. Consequently the 12th U.S. Census in 1900 furnished particularly outstanding evidence of the possibilities of the system. The population volume was ready one year and seven months from the start of enumeration; whereas it was estimated that hand tabulation of the three factors alone of sex, nativity and occupation would have required the services of 100 clerks for seven years and 11 months. Since 1901 its commercial utility has been greatly increased. Whenever a transaction involves a number of amounts which are subsequently to be used as units two or more times in compiling various totals, it has been found to be generally economical to "translate" it on to a perforated card. If, for instance, the data connected with the cost of production of a certain part are recorded on a card this can then be used in computing totals of individual wages, de-

partment costs, machine costs, productive hours, etc. The tabulating method is now to be found in general use throughout the world.

The card upon which the data are recorded in the form of perforations has a column for each number or symbol to be entered The digits 0 to 9 are denoted by holes punched proportionate distances from the bottom edge of the card starting with the 9 position Above the 0 position is space for two additional perforations which are used principally for actuating certain control operations of the machine. These additional positions may also be used for special classification numbers or, in combination with perforations in the regular digit position, to denote alphabetical characters. The card is divided vertically into "fields" each denoting a particular fact of the total information recorded. Certain information is descriptive while other is quantitative. The former class controls sorting and indicating, while the latter represents amounts to be totalled. Sorting and totalling are accomplished by different machines. Three separate mechanical devices are necessary to the system: a perforating machine or punch, a sorter and a tabulator. The ordinary form of perforating machine has a set of 12 punches under which the card is advanced a column at a time. By means of a skip bar or stops, certain fields can be skipped where no punching is to be done There are also more complete types of perforating machines arranged to permit automatic duplication of information already on one card on to others, to "gang" punch any predetermined number of cards with identical data, to number cards consecutively as they are punched. The speed with which trained operators can perforate the cards depends on the nature of the information being recorded as well as its extent. An output of 350 punched cards per hour might be considered an average performance.

Sorting the cards into the desired groups for tabulation is done at the rate of about 300 cards per minute for each digit of the class number. One well known form of sorting machine has 13 pockets, one for each possible columnar perforation and one for "rejects." The tabulator, or accounting machine, which totals the amounts perforated in given fields is capable of several different applications. The simplest form of this device consists of a set of counters actuated through a reading mechanism. Two methods of reading the cards are in use: electrical and mechanical In the former, brushes make electrical contact through the perforations thereby actuating magnets to trip the counters. The mechanical method employs a full set of pins which are brought down upon the card momentarily at rest and which penetrate the perforations to actuate the counters mechanically. Printing tabulators are arranged to either total the cards at high speed—about 150 per minute—and then print the total, or list each card individually at slower speed followed by a total for the group By means of special control features the machines automatically take totals of several fields after each sorted group and also store the amounts for grand totals. A great deal of flexibility is attainable in the way the items and totals may be made to appear on the printed sheet. Mechanism has lately been incorporated accomplishing direct subtraction without the necessity of perforating the complements of the numbers as formerly required. This permits of reports showing total credit and debit amounts and net balance. By using combinations of two or more holes in a column it is possible to list alphabetical characters as well as numbers With alphabetical printing, addition or subtraction automatically sensed by the machine and devices added to the printing section for handling report and bill forms, there are now means available for automatic accounting. (B. To)

TACANAN, a small group of tribes of South American Indians, constituting an independent linguistic stock. The Tacanas, from whom the stock takes its name, and their related tribes, live in north-western Bolivia, in the region just east of Cuzco, on the upper Madre de Dios river and its tributaries, and extend eastwards, between 13° and 15° S. lat., as far as the Beni. They are an agricultural as well as hunting and fishing folk, of the sedentary type, showing, apparently, considerable differences in cultural development between the different tribes. In spite of their close proximity to Cuzco, no significant study of this group has ever been made.

See A. D'Orbigny, *L'Homme Americain* (Paris, 1839); N. Armentia, *Navigacion del Madre de Dios* (La Paz, 1887).

TACHEOMETRY, a system of rapid surveying by which the positions of points on the earth's surface—both horizontal and vertical—are determined without using a chain or tape, or a separate levelling instrument. The ordinary methods of surveying with a theodolite, chain and levelling instrument are fairly satisfactory when the ground is clear of obstructions and not too precipitous. When the ground is much covered with brush or broken by ravines, chain measurements are both slow and liable to considerable error; the levelling, too, is carried on much slower though without serious loss of accuracy

These difficulties led to the introduction of tacheometry, in which, instead of the pole formerly employed to locate a point, a staff similar to a level staff is used, having heights marked from the foot and graduated according to the form of tacheometer in use The asimuth angle is determined as formerly The horizontal distance is determined by two methods (1) from the vertical angle between the well defined points on the staff and the known distance between them, or (2) fixed wires in the diaphragm of the telescope. The difference of height is computed from (1) the angle of depression or (2) elevation of a fixed point on a staff and the horizontal distance already obtained Thus all measurements requisite to the location of a point, both vertically and horizontally with regard to the point where the tacheometer is centred, are determined by an observer at the telescope without any assistance other than that of a man to hold the staff (*See* SURVEYING)

TACHIEN-LU: *see* TATSIEN-LU

TACHOMETER, an instrument for measuring the speed of rotation of shafts and machine elements Most tachometers have a rotating part which must be connected with the element whose speed is to be measured With the hand-type this driving relation is maintained only long enough to take a reading, while with the types that are mounted on a machine the instrument is permanently connected to the rotating part and indicates the speed as long as that part is in motion. The hand-operated type usually has a stem provided with a vulcanized rubber tip of conical form which can be pressed into the centre-hole of the rotating shaft. Permanently mounted tachometers are driven by belt or flexible shaft, or through a mechanical coupling.

There are quite a number of different principles upon which the design of a tachometer may be based. All of the principles used in speedometers (*q v*) lend themselves equally well to the design of tachometers In fact, a speedometer is a tachometer placed in driving connection with a road wheel and graduated in miles per hour instead of in revolutions per minute Thus, there are centrifugal, magnetic drag, clockwork and magneto-type tachometers. In addition there is the principle of vibrating reeds which seems to have been used for tachometers only. It is based on the fact that in most machines having large revolving parts, such as steam turbines and electric generators, vibration of the frame is synchronous with rotation of the revolving part.

The Frahm vibrating reed tachometer consists of a series of calibrated steel reeds of different lengths, having one of their ends mounted in a brass block and a short length at their other end turned at right angles and enamelled white. These enamelled ends are located side by side in a rectangular opening in the case. With the instrument mounted on the machine (or merely held against it by hand), and the machine in operation, one or more of the reeds will respond visibly to the vibration of the machine. The speed of rotation of the shaft can be gauged to a much closer limit than the difference between the speeds indicated by adjacent vibrating reeds, usually 50 revolutions per minute. Reed tachometers are made for speeds of from 800 to 12,000 revolutions per minute. Preferably the range of any particular instrument should not exceed an octave, as if it does, and the actual speed corresponds to a reed near the lower end of the scale, both the reed located there and a reed corresponding to twice this speed will vibrate.

TACHYLYTE or **TACHYLITE,** in petrology the glassy variety of basic igneous rock as basalt or dolerite. Tachylytes are black in colour, with a pitch-like or resinous lustre, and in the thinnest sections are typically brown and translucent, the glass being crowded with granules of magnetite. They are found only under conditions which imply rapid cooling, and are much less common than the corresponding acid volcanic glasses, principally on account of the greater fluidity and greater power of crystallization which basic lavas possess. The principal mode of occurrence of tachylyte is as a chilled edge or selvage to thin dikes or sills of basalt or dolerite. This edge may be only a fraction of an inch in thickness and merges inward into crystalline basalt. Tachylytes of this nature are common among the Tertiary igneous rocks of the Western Isles of Scotland (Skye and Mull).

Exceptionally, tachylyte constitutes almost entire lava flows, as in the Hawaiian islands. The rapid cooling of the highly fluid lavas of this region has inhibited crystallization, giving rise to vast floods of basaltic glass containing only minor amounts of crystalline material. Lastly, tachylytes occur as scoria or bombs thrown out by basaltic volcanoes. These are well known at Stromboli, Etna and in Iceland. Tachylytes readily undergo weathering and alteration, and are converted by oxidation and hydration into palagonite, a red, brown or yellow cryptocrystalline material. (C. E. T.)

TACITUS, CORNELIUS (*c.* 55–120), Roman historian, lived through the reigns of the emperors Nero, Galba, Otho, Vitellius, Vespasian, Titus, Domitian, Nerva, and Trajan. All we know of his personal history is from allusions to himself in his own works, and from 11 letters addressed to him by his very intimate friend, the younger Pliny. The exact year of his birth is a matter of inference, but it may be approximately fixed near the close of the reign of Claudius. Pliny indeed, though himself born in 61 or 62, speaks of Tacitus and himself as being "much of an age" (Pliny, *Epp.* vii.20), but he must have been some years junior to his friend, who began, he tells us, his official life under Vespasian (*Hist.* i.1), no doubt as quaestor, and presumably tribune or aedile under Titus (80 or 81), at which time he must have been 25 years of age at least. Of his family and birthplace we know nothing certain; we can infer nothing from his name Cornelius, which was then very widely extended; but the fact of his early promotion seems to point to respectable antecedents, and it may be that his father was one Cornelius Tacitus, who had been a procurator in one of the divisions of Gaul, to whom allusion is made by the elder Pliny in his *Natural History* (vii.76). But it is all matter of pure conjecture, as it also is whether his "praenomen" was Publius or Gaius. The most interesting facts about him to us are that he was an eminent pleader at the Roman bar, that he was an eye-witness of the "reign of terror" during the last three years of Domitian, and that he was the son-in-law of Julius Agricola. This honourable connection, which testifies to his high moral character, may very possibly have accelerated his promotion, which he says was begun by Vespasian, augmented by Titus, and still further advanced by Domitian, under whom we find him presiding as praetor at the celebration of the secular games in 88, and a member of one of the old priestly colleges, to which good family was an almost indispensable passport. Next year, it seems, he left Rome and was absent till 93 on some provincial business, and it is possible that in these four years he may have made the acquaintance of Germany and its peoples. His father-in-law died in the year of his return to Rome. In the concluding passage of his *Life of Agricola* he tells us plainly that he witnessed the judicial murders of many of Rome's best citizens from 93 to 96, and that being himself a senator he felt almost a guilty complicity in them. With the emperor Nerva's accession his life became bright and prosperous, and so it continued through the reign of Nerva's successor, Trajan, he himself, in the opening passage of his *Agricola,* describing this as a "singularly blessed time"; but the hideous reign of terror had stamped itself ineffaceably on his soul, and when he sat down to write his *History* he could see little but the darkest side of imperialism. He was an academic republican, like many of those who perished in that reign of terror. They were innocent in many cases of plotting against the emperor's life; and, no doubt, many of the plots were imaginary. But some had been real, and Domitian was determined to take no risks. Hence academic sympathizers with republican ideals fell under suspicion and were involved in the indiscriminate slaughter of those three years.

He was apparently convinced that Tiberius had been a ruler of the same type as Domitian; and that prejudiced him against the great, but grim, successor of Augustus. Moreover, some of the memoirs, contemporary with Tiberius' reign, were not likely to depict him in a favourable light, and on those Tacitus had largely drawn. (For the value of this evidence *see* Furneaux, Tac., Ann. vol. i. p. 20 *ad fin.* For Tacitus' judgment on Tiberius see *ibid.* Introduction ch. viii.) But, apart from personal prejudice, the Romans of the upper classes who lived in Rome or resorted thither tended to dislike imperial rule both socially and politically, and did, as a fact, see so much of the worst of it that they failed to appreciate the blessings it had conferred on the world outside. To his friend, the younger Pliny, we are indebted for the little we know about his later life. He was advanced to the consulship in 97, in succession to a highly distinguished man, Verginius Rufus, on whom he delivered in the senate a funeral eulogy. In 99 he was associated with Pliny in the prosecution of a great political offender, Marius Priscus, under whom the provincials of Africa had suffered grievous wrongs. The prosecution was successful, and both Tacitus and Pliny received a special vote of thanks from the senate for their conduct of the case. It would seem that Tacitus lived to the close of Trajan's reign, as he seems (*Ann.* ii.61; iv.4) to hint at that emperor's extension of the empire by his successful Eastern campaigns from 115 to 117. Whether he outlived Trajan is a matter of conjecture. It is worth noticing that the emperor Tacitus in the 3rd century claimed descent from him and directed that ten copies of his works should be made every year and deposited in the public libraries. He also had a tomb built to his memory, which was destroyed by order of Pope Pius V. in the latter part of the 16th century.

Pliny, as we see clearly from several passages in his letters, had the highest opinion of his friend's ability and worth. He consults him about a school which he thinks of establishing at Comum (Como), his birthplace, and asks him to look out for suitable teachers and professors. And he pays (*Epp.* vii.33.) him the high compliment, "I know that your *Histories* will be immortal, and this makes me the more anxious that my name should appear in them."

The following is a list of Tacitus' remaining works, arranged in their probable chronological order, which may be approximately inferred from internal evidence:—(1) the *Dialogue on Orators,* about 76 or 77; (2) the *Life of Agricola,* 97 or 98; (3) the *Germany,* 98, published probably in 99; (4) the *Histories* (*Historiae*), completed probably by 115 or 116, the last years of Trajan's reign (he must have been at work on them for many years); (5) the *Annals,* his latest work probably, written in part perhaps along with the *Histories,* and completed subsequently to Trajan's reign, which he may very well have outlived.

The *Dialogue on Orators* discusses, in the form of a conversation which Tacitus professes to have heard (as a young man) between some eminent men at the Roman bar, the causes of the decay of eloquence under the empire. There are some interesting remarks in it on the change for the worse that had taken place in the education of Roman lads. The style of the *Dialogue* is far more Ciceronian than that of Tacitus' later work, and critics have attributed it to Quintilian; but its genuineness is now generally accepted. It is noticeable that the mannerisms of Tacitus appear to develop through his lifetime, and are most strongly marked in his latest book, the *Annals.*

The *Life of Agricola,* short as it is, has always been considered an admirable specimen of biography. The great man, with all his grace and dignity, is brought vividly before us, and the sketch we have of the history of Britain under the Romans gives a special interest to this little work.

The *Germany,* the full title of which is "Concerning the geog-

raphy, the manners and customs, and the tribes of Germany," describes with many suggestive hints the general character of the German peoples and dwells particularly on their fierce and independent spirit, which the author evidently felt to be a standing menace to the empire. The geography is its weak point; much of this was no doubt gathered from vague hearsay. Tacitus dwells on the contrast between barbarian freedom and simplicity on the one hand, and the servility and degeneracy of Roman life on the other.

The *Histories,* as originally composed in 12 books, brought the history of the empire from Galba in 69 down to the close of Domitian's reign in 97. The first four books and a small fragment of the fifth, giving us a very minute account of the eventful year of revolution, 69, and the brief reigns of Galba, Otho, and Vitellius, are all that remain to us In the fragment of the fifth book we have a curious but entirely inaccurate account of the Jewish nation, of their character, customs and religion, from a cultivated Roman's point of view, which we see at once was a strongly prejudiced one.

The *Annals*—a title for which there is no ancient authority, and which there is no reason for supposing Tacitus gave distinctively to the work—record the history of the emperors of the Julian line from Tiberius to Nero, comprising thus a period from A D. 14 to 68 Of these, nine books have come down to us entire; of books v., xi and xvi. we have but fragments, and the whole of the reign of Gaius (Caligula), the first six years of Claudius, and the last three years of Nero are wanting. Out of a period of 54 years we thus have the history of 40 years.

The principal mss. of Tacitus are known as the "first" and "second" Medicean—both of the 10th or 11th centuries. The first six books of the *Annals* exist nowhere but in the "first Medicean" ms., and an attempt was made in 1878 to prove that the *Annals* are a forgery, by Poggio Bracciolini, an Italian scholar of the 15th century, but their genuineness is confirmed by their agreement (*see* Introduction to vol. i., of Furneaux's edition of the *Annals* of Tacitus, Clarendon Press series, 1884) in various minute details with coins and inscriptions discovered since that period. Moreover, Ruodolphus, a monk, writing in the 9th century, shows that he is acquainted with a ms. of Tacitus containing at least the first two books. Add to this the testimony of Jerome that Tacitus wrote in 30 books the lives of the Caesars and the evidence of style, and there can be no doubt that in the *Annals* we have a genuine work of Tacitus.

Much of the history of the period described by him, especially of the earlier Caesars, must have been obscure and locked up with the emperor's private papers and memoranda. As we should expect, there was a vast amount of floating gossip, which an historian would have to sift and utilize as best he might Tacitus, as a man of good social position, no doubt had access to the best information and must have talked matters over with the most eminent men of the day. There were several writers and chroniclers, whom he occasionally cites but not very often; there were memoirs of distinguished persons—those, for example, of the younger Agrippina, of Thrasea, and Helvidius. There were several collections of letters, like those of the younger Pliny; a number, too, of funeral orations; and the "acta senatus" and the "acta populi" or "acta diurna," the first a record of proceedings in the senate, the latter a kind of gazette or journal. Thus there were the materials for history in considerable abundance, and Tacitus was certainly a man who knew how to turn them to good account. He has given us a striking, and on the whole doubtless a true, picture of the empire in the 1st century. The rhetorical tendency which characterizes the "silver age" of Roman literature gives perhaps exaggerated expression to his undoubtedly strong sense of the badness of individual emperors, but he assuredly wrote with a high aim, and we may accept his own account of it (*Ann.* iii., 65): "I regard it as history's highest function to rescue merit from oblivion, and to hold up as a terror to base words and actions the reprobation of posterity." He is convinced of the degeneracy of the age, though it be relieved by the existence of truly noble virtues; and he connects this degeneracy more or less directly with the imperial régime. But it is difficult to dogmatize as to Tacitus' political ideals. He is primarily concerned rather with ethics than with politics; though he may feel that the world is out of joint—with whatever sentimental sympathy he may regard the age of "liberty" and admire the heroic epoch of the republic—yet he appears to realize that the empire is a practical necessity, and to the provinces even a benefit. Like the Stoics, with whom otherwise he has little in common, he censures rather individual rulers than the imperial system. But "the key to the interpretation of Tacitus," it has been well said, (Dill, *Roman Society from Nero to Marcus Aurelius,* Bk i.ch.1.) "is to regard him as a moralist rather than a politician." Perhaps the strongest work in the *Annals* and *Histories* is the delineation of character.

Tacitus gives us no certain clue to his religious belief. His expressions of opinion about the government of the universe are difficult to reconcile with each other There seems to have been a strange tinge of superstition about him, and he could not divest himself of some belief (*Ann.* vi. 21,22.) in astrology and revelations of the future through omens and portents, though he held these were often misunderstood and misinterpreted by charlatans and impostors On the whole he appears to have inclined to the philosophical theory of "necessitarianism," that every man's future is fixed from his birth; but we must not fasten on him any particular theory of the world or of the universe. Sometimes he speaks as a believer in a divine overruling Providence, and we may say confidently that with the Epicurean doctrine he had no sort of sympathy.

Tacitus' style is discussed in the article LATIN LANGUAGE Whatever judgment may be passed on it, it is certainly that of a man of genius, and cannot fail to make a deep impression on the studious reader. Tacitean brevity has become proverbial, and with this are closely allied an occasional obscurity and a rhetorical affectation which his warmest admirers must admit He has been compared to Carlyle; and both certainly affect singularity of expression But they are alike only in the brevity of sentences, and the brevity of Carlyle is not that of an artist in epigram Tacitus was probably never a popular author; to be understood and appreciated he must be read again and again, or the point of some of his acutest remarks will be quite missed.

Tacitus has been many times translated, in spite of the very great difficulty of the task; the number of the versions of the whole or part is stated as 393.

Murphy's translation (we should call it a paraphrase) was for long one of the best known; it was published early in the 19th century. On this was based the so-called Oxford translation, published by Bohn in a revised edition. Messrs. Church and Brodribb's translation and Professor Ramsay's (1904) (the latter of *Annals* i-iv) are much better. Of the many commentaries *see* Ritter's (1864); Nipperdey's (1879); Heräus's (*Histories,* 1885); Furneaux's (*Annals,* i vi, 1884; xi-xvi. 1891; *Germania,* 1894); Spooner's (*Histories,* 1891) The last two editors' introductions are particularly useful. By far the best edition of the *Agricola* in English is that of Furneaux as revised by Anderson (Clarendon Press, Oxford). Of works relating to Tacitean Latinity, Draeger's *Syntax und Stil des Tacitus* is the best.

(W. J. BR.; X)

TACITUS, MARCUS CLAUDIUS, Roman emperor from Sept. 25, A D. 275 to April 276, was a native of Interamna (Terni) in Umbria In the course of his long life he held various civil offices, including that of consul in 273. Six months after the assassination of Aurelian he was chosen by the senate to succeed him, and accepted by the army. During his brief reign he set on foot some domestic reforms, and sought to revive the authority of the senate, but, after a victory over the Goths in Cilicia, he succumbed to hardship and fatigue (or was slain by his own soldiers) at Tyana in Cappadocia. Tacitus, besides being a man of immense wealth (which he bequeathed to the state), had considerable literary culture, and claimed descent from the historian.

See Life by Vopiscus in *Historiae Augustae Scriptores;* also Eutropius, ix. 10; Aurelius Victor, *Caesares,* 36; Zonaras xii. 28; H. Schiller, *Geschichte der römischen Kaiserzeit,* i. 1883.

TACK: *see* NAIL.

TACNA, a province of Chile, which by the terms of the 1929 settlement of the Tacna-Arica question (*q.v.*) will be transferred to Peru It is bounded north by Peru, east by Bolivia, south

by Tarapaca and west by the Pacific. Area, 9,251sq.m. Pop. (1895) 24,160; (1920) 36,912. It belongs to the desert region of the Pacific coast. There are a few fertile spots near the mountains, where mountain streams afford irrigation and drinking water, and support small populations. None of its streams crosses the entire width of the province; they are all lost in its desert sands. The climate is hot, and earthquakes are frequent and sometimes violent. One railway in the province runs from the city of Tacna to Arica (*q.v.*), and another, constructed by the Chilean government, from Arica to La Paz, Bolivia. The province consists of two departments, Tacna and Arica, which once formed part of the Peruvian department of Moquegua. Its capital is Tacna (pop. 1895, 9,418; 1920, 14,376), a small inland town 48m. by rail from Arica, in a fertile valley among the foothills of the Andes. Existence is made possible in this oasis by a small mountain stream, also called Tacna, which supports a scanty vegetation. The town is the residence of a number of foreign merchants. (*See* also TACNA-ARICA QUESTION.)

TACNA-ARICA QUESTION. The war between Chile and Peru, begun in 1879, was terminated by a treaty of peace on Oct. 20, 1883, known as the Treaty of Ancón. Article 3 provided that the Peruvian provinces of Tacna-Arica should be held by Chile for ten years, after which a plebiscite would determine the sovereignty of those provinces. The country winning the provinces would pay to the other 10,000,000 Chilean silver pesos or Peruvian soles; a special protocol would prescribe the manner in which the plebiscite would be carried out. In 1892 negotiations were entered into between Chile and Peru for carrying out the plebiscite, but these and subsequent ones were unsuccessful. In 1922, however, at the invitation of the United States, issued at the suggestion of Chile and Peru, both Governments sent representatives to Washington and a protocol of arbitration was drawn up on July 20, 1922, which set forth that the only outstanding questions between the two countries were those relating to the unfulfilled provisions of Article 3 of the Treaty of Ancón, which should be submitted to the United States for arbitration.

Plebiscite Ordered.—In considering whether or not a plebiscite should be held the arbitrator had to determine: (1) whether the parties had acted in good faith in not coming to an agreement regarding the special protocol determining the terms of the plebiscite; (2) whether Chile's administration of the provinces had been such that a free and fair election could be held. The arbitrator decided the first question in the affirmative; and respecting the second, although far from approving the course of Chilean administration or condoning the acts committed against Peruvians, found no reason to conclude from the evidence submitted that a fair plebiscite could not be held under proper conditions.

In order appropriately to supervise and have general control over the plebiscite, the award set up a plebiscitary commission acting by majority vote, consisting of three members, one each appointed by Chile and Peru and the third, who should be president, appointed by the U.S. President. Registration and election boards were also provided. The arbitrator also reserved the right to entertain an appeal from the acts of the plebiscitary commission, which was to assemble at Arica not later than six months after the rendition of the award, and proceed at once to formulate rules for its own procedure and regulations governing the plebiscite and to fix the time and places for voting. The arbitrator provided that the 10,000,000 pesos should be paid: 1,000,000 in 10 days after the arbitrator's proclamation of the result of the plebiscite, a second 1,000,000 within the following year and 2,000,000 at the end of each of the subsequent four years. The customs revenues of Arica were assigned as security. The arbitrator decided that the Peruvian provinces of Tacna-Arica as on Oct. 20, 1883, constituted exclusively the territory in dispute, and that no part of the Peruvian province of Tarata was included therein. Tarata was transferred by Chile to Peru on Sept. 1, 1925, the definite boundary being left for a boundary commission.

Objections of Peru.—On April 2, Peru objected to the finding of the arbitrator for a plebiscite, maintaining that the meaning of the Spanish text of the Treaty of Ancón was "upon," "at" or "immediately after" the expiration of the ten years. Peru also requested guarantees for the voting, including immediate evacuation of the territory by the Chilean civil and military authorities and their replacement by Americans. The arbitrator replied on April 9, pointing out the agreed finality of the award and that the translation complained of was the one submitted by Peru. The problem before him was one of substance, of construction rather than of translation, a problem which had been debated by the parties long before the arbitration gave rise to any question of English translation. As to Americans taking over control of the provinces, the arbitrator found that this request went beyond the scope of his authority.

Meeting of Commission.—The plebiscitary commission met at Arica on Aug. 4, 1925, and drew up its rules of procedure. On Dec. 16, Chile appealed to the arbitrator from a resolution of the commission making the date of the plebiscite, she thought, conditional upon Chile complying with certain regulations of the commission. Chile took the position that by these regulations the commission exceeded its power and infringed upon her administrative control of the provinces and that the commission's control over the plebiscite began only with the registration of voters. Chile later withdrew the appeal regarding dates, and the arbitrator, in a decision dated Jan. 15, 1926, permitted its withdrawal. He pointed out at the same time that the submission agreed that the arbitrator should determine conditions of the plebiscite; that he had established a plebiscitary commission whose requirements had the same binding effect as if prescribed by him; and that conditions for holding a fair plebiscite became the concern of the commission from its organization.

The arbitrator held that while the territory remained in Chile's possession and subject to Chilean laws and authority pending the plebiscite, the possession and administrative authority were subject to the provision for holding the plebiscite, the award having stated that the exercise by Chile of legislative, executive and judicial power should not go to the extent of frustrating the provision for a plebiscite. The execution of the requirements of the plebiscitary commission was, therefore, but the exercise by both parties of their jurisdiction respectively in accordance with their agreement, and was not in derogation of the administrative authority of Chile.

On Feb. 16, 1926, the American Government proffered its good offices to Chile and Peru in an endeavour to adjust the differences, on the understanding that pending such an adjustment the authority of the plebiscitary commission should be maintained unimpaired. The American offer was accepted by Chile on Feb. 19, with the proviso that the arbitral award must be submitted for approval to the respective constitutional bodies. Peru was unable to accept the offer, and on March 11, the American ambassador at Santiago submitted a further memorandum to the Chilean Government explaining his Government's interpretation of the term "good offices." Chile reiterated her acceptance of the offer, and Peru having accepted, the secretary of State, through the American ambassador, on March 25, suggested that the plebiscitary proceedings should be temporarily suspended.

Chile and Peru appointed plenipotentiaries who met with the secretary of State on April 6. The secretary made proposals for the division of the territory between Chile and Peru, for the neutralization of the provinces, for the transfer of the provinces to a third party and finally a proposal for a corridor to the sea for Bolivia, the territory to the north thereof to go to Peru, to the south thereof to Chile, equitable compensation being made for improvements, etc. None of these proposals was accepted by both parties. The last proposal was accepted by Peru, but Chile desired something more definite, namely, the defining of the boundaries of the corridor, and made a proposal setting forth the limits of the corridor. This last proposal was rejected by Peru.

In the meantime conditions in the provinces had not been improved and the plebiscitary commission, being pressed by the Chilean member to fix the date for the elections, voted a resolution on June 14 declaring that Chile having failed in its obligation to create and maintain conditions proper and necessary for the holding of a free and fair plebiscite, the commission found that this failure had frustrated the efforts of the commission to

hold the plebiscite as contemplated by the award and had rendered its task impracticable of accomplishment. The commission therefore decided that a free and fair plebiscite as required by the award was impracticable of accomplishment and that the plebiscitary proceedings be terminated. The commission thereupon closed up its work.

Intimations received during the summer of 1926 from both Chile and Peru led the secretary of State to make a final proposal of settlement on Nov. 30, 1926. His suggestion that the territory in dispute be given to Bolivia was not accepted, however, and, all types of possible solutions having been proposed and rejected, no further suggestions for a settlement were made However, relations between the two countries gradually became more satisfactory, especially after the Sixth International Conference of American States at Havana, in January and February 1928, and the secretary of State on July 9, 1928, suggested to both Governments the re-establishment of diplomatic relations as "a favourable means for facilitating the definite removal of all existing misunderstandings and hence lead to permanent readjustment of the relations between the two countries mutually satisfactory to both." This suggestion was received favourably by both Governments and diplomatic relations were re-established on Oct. 3, when the Chilean ambassador presented his letters of credence to the President of Peru The Peruvian ambassador presented his letters of credence to the President of Chile two days later.

Negotiations for a settlement were entered into and continued until May 14 when the President of the United States, not as arbitrator but in the exercise of good offices at the request of the parties, submitted to the American ambassadors at Lima and Santiago a proposal as the final bases of a solution. This provided that the territory should be divided, Tacna to Peru, and Arica to Chile; the dividing line to start at a point on the sea coast to be called "Concordia," ten kilometres to the north of the bridge over the River Lluta and to continue parallel to the Arica-La Paz Railroad following the topographic features The sulphur deposits of Tacora remain in Chilean territory and the Uchusuma and Mauri canals remain the property of Peru In case of disagreement, a third person designated by the President of the United States shall render the final decision Chile will construct for Peru at Chile's expense within the Bay of Arica a wharf, customhouse and station for the railway from Tacna to Arica, Peru to enjoy all the privileges of a free port. Chile is to deliver to Peru the sum of six million dollars and also to deliver, without cost to Peru, all public works already constructed and all Government owned real property in the Department of Tacna. Chile is to maintain in the Department of Arica the franchise granted by Peru in 1852 to the Arica-Tacna Railroad Company and to deliver the Department of Tacna thirty days after the exchange of ratifications. Private property legally acquired in the territory under their respective sovereignties is to be respected by both Governments. A monument commemorating the consolidation of their friendly relations will be erected by the two Governments on the Morro de Arica. The children of Peruvian nationals born in Arica will be considered Peruvians until the age of twenty-one years, at which time they may elect their definitive nationality; Chileans born in Tacna will enjoy the same right. Both Governments agree to release the other from any obligation or indebtedness between them whether derived from the Treaty of Ancón or not:

In presenting this proposal to the two Governments, the American ambassadors at Lima and Santiago stated that the proposal was not to be interpreted as indicating that either the President or Government of the United States expressed any opinion or made any suggestion whatever regarding any future disposition by either party of that portion of the territory in dispute which would be in its possession should the proposal be accepted by the two Governments. Chile accepted the proposal on May 15, 1929, and Peru on May 16, 1929. (F. WE.)

TACOMA, a city of Washington, U.S.A., on Commencement bay, one of the arms of Puget sound, 30 m. by water south of Seattle and 151 nautical miles from the Pacific ocean; a port of entry and the county seat of Pierce county. It is on Federal highway 99 and the Pacific coast air-mail route, and is served by the Chicago, Milwaukee, St. Paul and Pacific, the Great Northern, the Northern Pacific and the Union Pacific railways, by interurban trolley and motor-stage lines, and by over 60 steamship lines, with sailings to the Orient, South America, Australia and Europe, and to Atlantic and Pacific ports of the United States. The population was 96,965 in 1920 (113·7 males to 100 females), of whom 21,705 were foreign-born, including 1,067 Japanese; and was estimated locally at 125,000 in 1928.

The fine natural harbour is 4·5 m. wide at its entrance between Point Brown and Point Defiance and about 2·5 m. long. There is no bar or other natural obstruction at the entrance, and the waters are deep throughout the entire extent. The climate is equable, and the precipitation moderate, about ⅔ of the rain falling in the four months November to February. From the tidelands the city rises gradually to a plateau 300 ft. high. The area (including 8·33 sq.m. annexed in 1927) is 51·26 sq.m., of which 4·91 sq.m. is water. The Olympic Mts. are visible to the west, and Mount Rainier (or Tacoma; 14,408 ft. high), in Rainier National park, 56 m. S.E., seems to stand at the city's doorway. Near by are four freshwater lakes, surrounded by evergreen forests. The city's parks cover 1,114 ac, including 640 ac. on Point Defiance. In the heart of the city is an outdoor stadium seating 40,000 spectators, and commanding an unobstructed view of the bay. Near it is the State historical building and the Ferry museum, containing a collection of Indian relics. In the north end of the city is the 40 ac. campus of the College of Puget Sound (Methodist; 1903). A zoning ordinance has been in effect since 1919, and an active programme of city-planning was undertaken in 1920. The assessed valuation of property for 1927 was $65,726,619. The city's water-supply and distributing system represents an investment of $7,602,888, and it has invested $13,183,872 in power-generating and distributing equipment, including hydro-electric plants near the base of Mount Rainier and in the foot-hills of the Olympics. By 1928 nearly 100,000 h p was developed, and under municipal ownership and operation (entered upon in 1893) rates for power had been reduced until they were the lowest in the country Two of the transcontinental railroads have extensive terminals on the waterfront, and other wharves have been constructed by industrial concerns. The physical development of the harbour by the public and the administration of facilities owned by the Port of Tacoma District (a municipal corporation conterminous with Pierce county) are under the jurisdiction of a port commission. The piers owned by the municipality cover 280 acres A municipal belt-line railway connects the railroads and the industrial district with the port. The traffic of the port in 1927 amounted to 4,751,162 tons, valued at $153,557,348, of which $49,299,590 represented exports to foreign countries, $18,899,029 imports and $85,358,729 domestic commerce with Alaska, Hawaii, California, the Atlantic Coast and the Gulf and local ports.

Manufactures.—The 600 manufacturing establishments of the city in 1927 had an output valued at $114,342,978 and a working force equivalent to 15% of the total population. The Tacoma Smelter (established in 1889 as a lead smelter, but handling chiefly copper since the opening of the copper mines in Alaska) receives 36,000 tons of ore annually, including some consignments from Europe, and ships 9,000 tons of refined copper, 250,000 lb. of arsenic and 550,000 oz. of gold and silver. Two of the transcontinental railways have repair and construction shops here, employing over 3,000 men. The annual output of the flour and cereal mills is valued at $18,000,000. The largest group of industries is that which manufactures lumber and lumber products, its output amounting to over $36,000,000 in a year. The annual lumber cut of the Tacoma district is 1,500,000,000 ft., and the city makes more fir doors, fir veneers, panels and wooden columns than any other city in the country.

History.—Tacoma harbour was visited by Capt. George Vancouver in 1792, and 30 years later the Hudson Bay Company established a trading-post at Nisqually. Commencement bay was surveyed for the United States in 1841 by Lieut. Charles Wilkes. Settlement began in 1852, when Nicholas Delin, a Swede, took

a claim on the south shore of the bay and set up a small saw-mill, from which in 1853 he shipped lumber to San Francisco. In 1855 the settlers were frightened away by the opening of the Indian war, taking refuge in Ft. Steilacoom (12 m. S.W.) which had been built in 1849; but in 1864 Job Carr and his two sons, from Indiana, took claims on the west shore of the bay. Development of a city dates from the arrival from Portland in 1868 of Gen. Morton Matthew McCarver. He induced settlers to come; persuaded two of them to erect a saw-mill; and planned a town site, confident that a transcontinental railway would soon reach Puget sound. The first name he chose for the town was Commencement City, but this was soon dropped for the Indian word meaning a snow-covered mountain. In 1873 the Northern Pacific established its terminal on Commencement bay and named it New Tacoma. A town was organized in 1874, becoming the county seat in 1880, and in 1883 the two settlements were consolidated and incorporated as the city of Tacoma. In 1880 the population was 1,098; in 1887, when the railroad was completed across the Cascades, it had grown to about 5,000. A boom immediately set in, attracting land speculators from all parts of the country, and three years later (1890) the population was 36,006. There was little increase in the next decade, but between 1900 and 1910 the population grew from 37,714 to 83,743, and the total increase of the 20 years 1900 to 1920 was 157%. In the first quarter of the 20th century the assessed valuation of property increased (roughly) threefold; postal receipts were multiplied by nearly 9; and the value of the foreign commerce by 5.

TACTICAL FORMATIONS. The line and the column are the two elementary tactical formations, their corollaries being the skirmishing line and the square. All other formations spring from these, and the smallest unit which can evolve them is one of four men and a leader. In practice, however, it has been found necessary to double the number of men so that they may work in pairs when an open square formation is required.

Line.—Organized warfare begins with the line, that is a row of men in shoulder to shoulder formation, cemented into a unit through mutual protection, co-ordinated movement and combined offensive power. The strength of a line of men depends on maintaining an unbroken front, consequently its power of resistance can be increased by deepening it by ranks, that is by placing line behind line so that should any of the front rank become casualties their places may be filled by the men in rear of them who, until called upon to fight, are in reserve. Whilst in ancient times the ranks were close together, because fighting was carried out with shock weapons, in modern times the distances between the ranks of the line have been greatly enlarged. The weak points in the line are its two flanks and particularly its rear. If held in front, the rear of a line can offer little resistance, and if the line is attacked in flank the number of fighters is so small when compared to the attackers that the front is generally rolled up.

Column.—The column is mainly a logistical formation, its simplest form being that of single, or Indian file. Its underlying idea is that of "follow my leader," for wherever the column leader goes all the men have to do is to follow him. A column is not an offensive formation but a mobile one, a reservoir of offensive power which only becomes dynamic when deployed into line. It is a misnomer to suppose that a charging column gains strength if its numbers are increased. This is not so, because its offensive power is concentrated in its front rank; but its depth gives it moral support, and above all provides reserves immediately at hand to take advantage of a break through. The Grecian phalanx was a formation of single file columns, eight deep, marshalled in close order, and it is interesting to note that a return to this formation was made by most armies during the World War of 1914–18, but with this difference, that the single files, each a section of 6 to 8 men, were spaced at considerable intervals, the whole front being covered by bullets in place of pikes.

Skirmishing Line.—A skirmishing line is a line in open order, and is generally formed by deploying men in pairs at fixed intervals between each pair. It is a more flexible formation than the line, and better suited to individual fighting and the development of missile fire; its power of resistance, save in broken country, is however slight. The skirmishing line is probably the oldest of all formations, it is also the most modern, because solid lines of men can no longer operate on the battlefield. The skirmishing line to-day is one composed of sections of men rather than of individuals, or pairs, which advance in single file and extend into skirmishing order.

Square.—The square is essentially a protective formation as it has four potential fronts, and so can guard itself on all sides. Solid squares of men were frequently used in classical warfare, and were the normal formation during the 16th century. Rallying squares formed by hastily grouping men together were mainly used to meet cavalry. In modern times the hollow square, such as used by the British in the Napoleonic wars and the Egyptian campaigns, was a common protective formation; and to-day a column secured by advanced, rear and flank guards is nothing more than an elastic, or open, square with a central reserve. The future of the square formation is likely to be considerable, seeing that in mechanized warfare fronts may be anywhere. *See* also Tactics. (J. F. C. F.)

TACTICS. The art of war differs from the science of war as action differs from theory. The second discovers the principles upon which the art of waging war is founded, and the first applies these principles according to conditions by means of the instrument of war—the forces employed to impose the will of one antagonist upon the other, whether this will is the will of an organized Government, or of a single man. Of all instruments of war man himself is the archetype, he is his own general, his own intelligence service, and he possesses power to move, guard and hit. From these natural powers are developed five essential tactical functions, namely, command, reconnaissance, security, mobility and offensive action; or planning, finding, protecting, manoeuvring and actual fighting. It is by the last of these that a commander finally imposes his will on his enemy through fear of destruction. These functions when combined may be divided under the headings of strategy and tactics; but in practice these two parts cannot be so easily separated, since strategy is the art of protected movement from which tactics, the art of protected offensive action, is developed. Whilst the one places an army in the best position to overcome its enemy's resistance, the other has for its object the economical development of pressure, so that movement in the desired direction may be maintained. Consequently it will be seen that whilst strategy aims at developing tactics, in its turn the aim of tactics is the development, or completion, of a strategical movement. In brief, the primary tactical function of battle is to generate mobility (strategy) through protected offensive action (battle).

The Decisive Point.—At once the question arises: Is it possible to lay down definitely the direction in which movement should be made? That is, can a commander off-hand decide on the decisive point of attack, that point which if struck in force will lead to the most economical destruction of the enemy's fighting power? The answer is "yes," for logically and historically it may be proved that the back of a man, or the rear of an army, is the decisive point to attack; that is, the point at which an enemy if struck can develop the least resistance and pressure, that is, where he is least well protected and least able to hit out. The validity of this statement can be readily proved by examining the organization of an army.

A modern army consists of three main tactical forces, namely, a reconnaissance force (cavalry), a protecting force (artillery), and an attacking force (infantry), these three forming the fighting body. Behind this body is situated the brain and internal organs, namely, the command, and the services of supply, maintenance, repair and evacuation. The body has power to hit and to guard, but of itself it possesses no power to co-ordinate its movements, or to supply itself and simultaneously maintain its tactical organization. Consequently, if it is deprived of its command, it is paralysed, and if deprived of its supplies, starved into surrender, or compelled to disperse. As neither the command nor the services possess power of exerting pressure or resistance physically, they form the decisive point of attack and defence. It follows, therefore, that whatever system of attack is adopted,

whether it be a frontal attack, a flank attack or a rear attack, the object of both sides is to destroy the power of command of the opposing side, either directly through an attack on this command, or indirectly by an attack on the body, or stomach, which it controls

Offensive and Defensive Action.—To attack presupposes offensive action, and this in its turn introduces defensive action, either to protect the attack or resist it. When the art of war is of a high order, the offensive and the defensive are so interwoven as to be inseparable, but as this degree of perfection has throughout military history been the exception rather than the rule, these two modes of fighting may be considered separately. The passive defence, that is a defensive which does not include mobile offensive action, has been justly condemned, yet it must be remembered that when in the form of purely defensive bodies of troops, or of fortresses, or fortified positions, it has been combined with mobile forces, it has more often than not proved itself a necessary operation. The active defence, that is the occupation of a position with a view to persuade an enemy to attack it, and then, when he has exhausted himself, counter-attack from it, has played as important a part in war as the offensive itself The adoption of such an attitude depends entirely on circumstances, and each case must be judged on its own merits Generally speaking, the active defence carries with it advantages of time, place and terrain, but for the moment it resigns the initiative by seldom being able to restrict the strategic mobility of the attacker

Anatomy of the Attack.—Turning now to the attack itself, in all such operations, and more particularly so in modern times, may be discovered a definite tactical anatomy First there is the act of approach, culminating in contact, which links strategy to tactics. Next there is the attack proper, and lastly the pursuit, or act of annihilation, which is virtually a new attack, and which should when possible be carried out by a fresh body of troops The attack may be divided into three acts, or stages First it is necessary to deprive the enemy of freedom of action; this is effected by deceiving him and surprising him, an attack on the mind of his command. By distracting and frightening him. an attack on his *moral.* And, finally, by compelling him to alter his dispositions, improvise new distributions, and force him to assume a defensive attitude, in other words to protect himself rather than hit out It is difficult to find a word which embraces the idea of all these actions; possibly "distraction" is the best, which literally means "to pull asunder," to perplex the enemy's mind, to harass his *moral,* and to confound his organization This distraction, or the upsetting of the enemy's mental, moral and physical equilibrium creates an opportunity for a decisive thrust, a dislocation of the enemy's plan which throughout history has commonly been achieved by a manoeuvre against the enemy's rear, or, failing his rear, one, or both, of his flanks. The result of this dislocation is that the enemy is compelled to make a complete "change of front" in plan and in distribution, so complete that frequently being forced to fight in two directions simultaneously he is deprived of all power to concentrate his forces Thus unhinged, and reduced to a state of mental bewilderment, moral paralysis and physical disorganization, he offers himself an easy target to the knock-out blow which entirely disrupts his army, reducing it to a mob to be annihilated by the pursuit Thus the attack may be divided into three acts, namely, distraction, dislocation and disruption, the one paving the way for the next and melting into it until the enemy's destruction is complete.

Tactical Elements.—Throughout history two main types of weapons have been used in attack and defence, namely, missile weapons and shock weapons. Frequently the first have gained supremacy in defensive actions when used by foot soldiers, and in offensive actions when used by mounted men. The second throughout the greater part of military history have *par excellence* constituted the weapon of the attack So much so has this been the case that until quite recently it may be said that the tactical object of missile weapons has been to assist, or restrict, the movement forward of the *arme blanche* Similarly, there have been two types of protection, and two types of movement, namely, direct protection by body armour, earth-works or terrain, and indirect protection by formation, invisibility and fire-power. Movement has been of two degrees—by foot and by horse. There have been also two main attack formations, the column and the line. The second is essential for the full development of missile weapons, and the first for what conventionally is called shock tactics. By this it must not be understood that weight of numbers endows a column with breaking power. In war there never is any shock of this description, for, as Commandant Colin says: *"an impulse never comes from the rear."* What depth does endow a column with is manoeuvrability, moral superiority, and above all, reserves at hand once the enemy's front has been shot, or hacked, through. In fact the column is a concentrated line in movement.

The simplest form of attack is one line or column meeting another line or column head on, this is known as the parallel order of battle. Generally speaking, as military history clearly shows, this order, the frontal fight, does not lead to a solution unless one side preponderates numerically, when the frontal attack of the stronger side develops into an overlapping attack, that is an attack which meeting with little or no resistance outflanks its opponent's front In this attack of mobile wings pivoted on a stable centre, which is holding the enemy, may be discovered the germ of all tactical development down to the present day. We will now trace the above theories throughout the recorded history of war.

THE ARCHAIC PERIOD

Leadership and the Phalanx.—The primitive tactics of the archaic period of war are not a thing of the past, for they may be witnessed daily in brawls, riots, individual contests and mob fighting They are brutal and cowardly, yet they form the nursery of individual courage and cunning, and from the earliest days onwards these two human qualities have stood in direct antagonism Even to-day the highest military rewards are given for bravery and not for intelligence, and still the introduction of any novel weapon which detracts from individual prowess is met by opposition Mob-fighting, whether on horse or foot, goes back to pre-cultural times; yet even then the idea of a leader must have existed, and it may be said that true military operations only began to take form when once a leader attained over his followers sufficient authority to order them out to fight or witness a fight, in place of merely assuming leadership during a haphazard brawl When this control was established, the true battle, as Homer often describes it, was waged between the leaders themselves, their followers frequently being mere audiences to cheer on their respective champions and villify those of their enemy If the followers engaged, and the tribal weapons were the spear and shield, it must soon have been obvious that the side which could first form a wall of men normally won. This wall is the beginning of the phalanx as known throughout Greece and depicted on the monuments of ancient Assyria and Egypt. The phalangites constituted the village, or city, militia. Their drill consisted in the "fall in" in lines, or ranks, and their tactics in forward or backward movement accompanied by push of pikes The phalanx possessed little or no power to attack the simplest defences, consequently if the enemy refused to abandon his city wall, or come out of his village, the only method whereby he could be brought to book was to attack him economically, that is to destroy his crops. This was the normal system of war in ancient Greece.

The Oriental Battle.—During this early period, strategy may be considered as purely one dimensional. There was little idea of manoeuvre. Armies set out with one thought, namely, to meet each other on some plain, or in some valley, and fight it out. There they extended into parallel lines, and the one with the greatest front normally won, because its wings meeting with no opposition were able to overlap its less extended adversary. As these wings had to move the furthest, when cavalry was employed, as in Persia, they were placed on the flanks of the infantry, and in front of this line frequently swarmed archers and slingers. The infantry were massed in solid squares from 30 to 100 ranks deep, and if chariots were used they were drawn up in front of the foot soldiers, or in the intervals between them. When once the

line of battle was ready, the light infantry cleared the front, the chariots charged the enemy to demoralize him, the infantry following them up to gain a decision. Meanwhile the cavalry attempted to sweep round the enemy's flanks, not so much to attack its adversary's rear as to pillage his baggage wagons. Given equal discipline and armament, and remembering that the infantry battle line was rigid and could not manoeuvre, these tactics leave little to be desired. Military superiority was based on numbers; which side could wash round, rather than manoeuvre round, the flanks of the other, this was the tactical problem. To hold men in reserve was futile, because this would have meant a shortening of the front of attack, and to manoeuvre squares of some 10,000 men standing on a 200yd. frontage was not possible with the drill of this period.

THE CLASSICAL AGE

Marathon and Plataea.—Though Aristides names Palamedes as the inventor of tactics, Nestor appears to have been the only general during the Homeric period who possessed tactical insight. He grouped the Greek army according to families to inculcate a spirit of rivalry, and divided it into a right, centre and left, placing his bravest warriors in the rear rank. From the Trojan War (1193–1184 B.C.) on to the first Messenian War (743–723 B.C.) no further innovation seems to have taken place, but in this war we find Euphaës, the Messenian general, handsomely beating the Spartans by a well-executed rear attack carried out by his cavalry. In spite of this admirable manoeuvre, one long known in the East but seldom well executed, the Spartans learnt nothing, the tactics of Euphaës on the field of Amphaea (730 B.C.) remained a sealed book to them, and no further progress was made in tactics until Miltiades, either intentionally or accidentally, won the battle of Marathon (*q.v.*) in 490 B.C., by a double development. Resting his wings on two small streams which prevented the Persians outflanking him, he made his centre weak and his wings strong with the result that when his centre was driven back his wings clinched inwards and took the Persians in flank. At the battle of Plataea (*q.v.*), fought in 479 B.C., though the Persians under Mardonius were taught a costly lesson when their cavalry attempted to charge unbroken infantry on the slope of a hill, the Greeks were taught an equally severe one when they believed that they could meet cavalry on any ground. The result was that it was only after this third invasion of the Persians that the Greeks, little by little, began to realize the importance of the mounted arm.

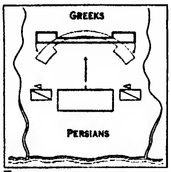

FIG. 1.—BATTLE OF MARATHON (490 B.C.), SHOWING TACTICS OF CONCENTRIC ATTACK

The Peloponnesian War.—The Peloponnesian War (431–404 B.C.) though it produced no general of the first order, shows a distinct advance in tactical knowledge. The sieges of Plataea (429 B.C.) and of Syracuse (415 B.C.) are a definite step forward in these operations. At the battle of Olpae in 426 B.C. Demosthenes, in command of the allies, defeated a superior Spartan army by a well-planned rear attack. Placing an ambush of 400 light troops behind the Spartan left wing he allowed his enemy to wash round both his flanks, whereupon the ambush fell upon the rear of the enemy's left wing, and put the whole army to flight. In his turn Brasidas, a Spartan, possessing none of the narrowness of his countrymen, by his rapid marches and sudden attacks, such as at Amphipolis (424 B.C.) showed that the value of mobility and surprise was fully realized by him. The main tactical lesson of this long war was the necessity for a well-trained light infantry for manoeuvre, seeing that cavalry were hard to come by in Greece. This, in the 4th century B.C. led to the reforms of Iphicrates. Hoplites were not only expensive to equip but immobile on any but unbroken ground, so Iphicrates lightened their equipment and produced a body of men known as peltasts, with whom he seriously injured the allies of the Lacedaemonians in the Corinthian War, and in 392 B.C. annihilated a Spartan Mora of 600 men.

The Development of the Oblique Order.—An interesting period in tactics is now entered, and one of rapid growth following on the footsteps of rapidly expanding culture. For centuries past there had been a tendency for the front of an attacking phalanx to drift towards its right, the reason being as Thucydides writes: "Because fear makes each man do his best to shelter his unarmed side with the shield of the man next on his right." This drift brought the right wings first in contact with their enemy, the left wings being somewhat refused; thus the parallel order tended towards an oblique order of attack. The tactical meaning of this drift seems to have been fully grasped by the Theban general Epameinondas. At the battle of Leuctra (*q.v.*) in 371 B.C. at the head of 6,000 to 8,000 men he met 11,000 Lacedaemonians under Cleombrotus. He changed the normal centre of gravity of the attack from right to left and so surprised his enemy and simultaneously reduced the chance of his right being defeated. He drew up his battle line, probably eight deep, and on its left marshalled a column of 1,500 men 48 deep. To secure the outer flank of this column he placed there the Theban Sacred Band, and in front of his left he drew up his cavalry squadrons. Ordering his right to move slowly and his left rapidly forward, he refused the Spartan left and destroyed the Spartan right; then he wheeled his column inwards, and took the whole of his enemy's army in enfilade, winning a battle of mind against some of the toughest muscle which ever took the field. Nine years later at Mantineia (*q.v.*) he repeated these tactics with signal success, but his death on the field robbed his victory of decisive results.

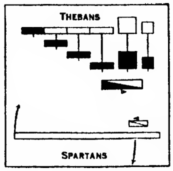

FIG. 2.—BATTLE OF LEUCTRA (371 B.C.), SHOWING TACTICS OF THE OBLIQUE ORDER

Philip of Macedon.—Let us briefly recapitulate the tactical possibilities thus far evolved, for we are about to enter a period when one man, Philip of Macedon, shook them together, creating perhaps the most perfect tactical instrument ever devised in the history of war. The following lessons had been learnt. The front of a phalanx of pikemen was inviolable on flat and unobstructed country, consequently the parallel order was obsolete. Its flanks were very vulnerable, consequently the oblique order of Epameinondas offered the best method of attacking heavy infantry with their like. For broken ground, mountain warfare and flank protection, light infantry were essential, and for rapidly outflanking an enemy and attacking him in rear cavalry were the decisive arm. The Persian Wars had taught the Greeks the danger of pitting heavy infantry against cavalry in cavalry country, and the danger of pitting cavalry against light infantry in light infantry country. Xenophon who was present at the battle of Cunaxa (*q.v.*) in 401 B.C. and in virtual command of the 10,000 during their famous retreat, produced in his Anabasis and his Cyropaedia the first great treatise on the art of war. All these things suddenly impinge on the fertile mind of Philip (382–336 B.C.). Out of them he constructed the perfect instrument—the army of Alexander.

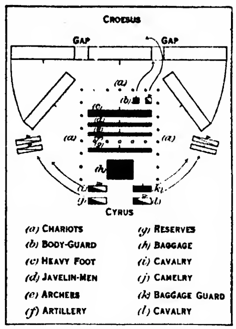

FIG. 3.—XENOPHON'S IDEA OF THE BATTLE OF THYMBRA (554 B.C.), SHOWING TACTICS OF EX-CENTRIC ATTACK

Whether consciously or not, it is not possible to say, he took as his tactical model the body of man and devised his organization accordingly. First he re-armed the phalanx with a longer pike, the Sarissa, and established it as the trunk or stable base of his army; it was in fact a mobile fortress the front of which defied attack. Having created this defensive base of operations he hinged on to it two arms, the left protective, to ward off blows,

and the right offensive to deliver them. Both these arms were composed of cavalry, heavy and light, the right wing being in quality and quantity the stronger. To maintain the maximum flexibility he inserted between these cavalry wings and the phalanx two joints, or bodies, of light infantry, the Hypaspists on the right and the Thracian Javelin-men on the left. On the outer flank of the right wing cavalry he placed a strong body of light infantry and archers Finally he organized a staff, a mobile artillery train, a body of engineers for siege work, and definitely established unity of command in the Macedonian army.

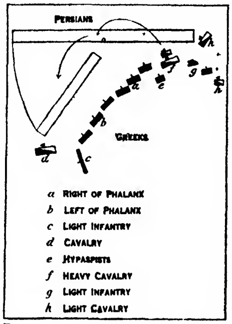

FIG 4.—BATTLE OF GAUGAMELA. (331 B C.), SHOWING TACTICS OF REAR ATTACK

Alexander the Great.—The perfection of this organization, probably the most efficient ever devised to meet the tactical conditions of its day, was fully proved in the campaigns of his son, Alexander the Great, who never lost a battle or a campaign, who invariably defeated his enemy on the plains, in the deserts and in the hills; who was never stopped by a mountain range or a river, and who reduced every fortress he laid siege to. In his four great battles against the Persians and Indians, namely, Granicus (*q.v.*) in 334 B.C , Issus (*q.v.*) in 333 B.C., Gaugamela (*q.v*) in 331 B C. and Hydaspes (*q.v.*) in 327 B C., though his grand tactics vary, his minor tactics uniformly are based on the cavalry charge, and spring fully armed and armoured from Philip's superb organization, their one aim being to develop mobility through protected offensive action They may be described as follows.

The tactical idea was to attack the enemy's command, the decisive point which, in the Persian army, was normally in the centre of the front rank. The method was an attack by cavalry which would roll up or penetrate the enemy's left wing, and so permit of the Persian command being attacked in rear. The pivot of the whole operation was the phalanx, which moved forward towards the enemy's left in echelon with its right leading, the cavalry wings doing likewise The left being refused enticed the enemy, especially his cavalry, to attack it. The object of the left wing was to draw the enemy towards it; it was consequently only sufficiently strong to hold its own Its right was protected by the impenetrable phalanx to which it was hinged by the Thracian light infantry. As the left wing swung back, the right wing, hinged to the phalanx by the Hypaspists, swung forward The light cavalry fixed the enemy's left wing, and the heavy cavalry forming the apex of an arrow formation (the phalanx in echelon on its left, right leading, and the light infantry in echelon on its right, left leading) struck the enemy a terrific blow, pierced him, wheeled round, charged the enemy's command, and then took the enemy's right wing which was opposed to the Macedonian phalanx, or driving back Alexander's left wing, in reverse. Once destroyed an immediate pursuit followed Such in brief were the tactics applied by Alexander.

The Decline of Greek Tactics.—The tactics employed by the Diadochi, his successors, were of a high order, for in spite of the fact that, during the last few years of Alexander's reign, the Macedonian army had become partially Orientalized, this though it detrimentally influenced its *morale* had actually enhanced its tactics by increasing its fire power. Archers were more extensively used, especially horse archers, and this brought siege and field artillery, in the shape of catapults and balistae more and more into use, especially under Demetrius Poliorcetes, the son of Antigonus.

In spite of inventions, tactical organization deteriorated and strategy advanced. Walled towns had now lost much of their defensive power, and the numerous combatants, all depending upon mercenary soldiers, made alliances and military combinations necessary. Command now took a more modern form, the commanders-in-chief—Antigonus, Seleucus, Ptolomy, etc., frequently planning the strategy of a campaign, and handing over tactical control to a hired subordinate. *Morale* steadily decreased as it must in ill-paid mercenary armies, and battles were frequently won by buying over the enemy's troops on the field itself. Though it is not possible to prove it, lack of trust in the cavalry and infantry compelled commanders more and more to rely on war elephants and artillery. Whatever was the cause, both came into general use, and by the time of Philopoemen battle fronts were sometimes covered by a veritable bombardment of bolts, arrows and balls, fired from catapults and balistae, as for instance at the third battle of Mantineia (*q.v.*) in 207 B.C. Yet the deterioration of tactics was progressive, and by the dates of the battles of Cynocephalae (*q v*) in 197 B.C. and Pydna (*q.v.*) in 168 B.C. they had so far retrogressed that the phalanx of Philip and that of Perseus had returned to the Spartan model, a wall of pikes with vulnerable flanks incapable of manoeuvring over broken ground. The exquisite combination and co-operation of arms which distinguished Philip of Macedon's army had been utterly forgotten.

The Early Legion.—The early Roman legion was very similar in organization to the Spartan phalanx. It was a city militia consisting originally of some 3,000 *milites,* or foot soldiers, and 300 *equites* who were not so much cavalry as well-to-do mounted infantry To it were added a number of *velites,* or untrained light infantry. Its tactical formation was phalangial Though this army was well suited to battles of push of pikes on the plains, it was ill suited to mountain warfare. The disaster suffered at the Caudine Forks (321 B.C), and the long drawn out Samnite wars (343–290 B C.) appear to have compelled the Romans to give up the purely linear formation of the phalanx, and substitute for it a more flexible one The legion was divided into 30 maniples placed chequerwise in three lines—*hastati, principes* and *triarii.* The third line was composed of veteran troops held in reserve.

To compare the legion at its prime, that is after the 2nd Punic War, with the phalanx in its decadence, or even with the phalanx under Pyrrhus (280–275 B.C), is absurd Though Pyrrhus was an able general he depended more on the use of elephants than on organization Philip of Macedon's model had by his day altogether deteriorated, and by the date of the 2nd and 3rd Macedonian Wars (200–194 and 176–168 B.C.), the Macedonian army had thrown back to the old Spartan model, yet it is interesting to note that both at Cynocephalae and Pydna it was a rear attack which decided the day in favour of the legion.

The 2nd Punic War.—When Hannibal invaded Italy in 218 B.C. the Roman legionaries were little more than a raw militia; yet, when he was defeated at Zama (*q.v.*) in 202 B.C , they were veterans ready to conquer the world. Sixteen years of incessant warfare had taught them, under such leaders as Claudius Nero, Marcus Livius and Scipio Africanus, how to wage war, but curiously enough it never taught them Hannibal's open secret (also Philip of Macedon's and Alexander's), namely, that cavalry is the decisive arm. It is true that Scipio Africanus realized this, and by launching Massinissa's Numidian horsemen on the rear of Hannibal's troops, won Zama, but throughout Roman history cavalry was seldom their decisive arm, they mainly depended on infantry, and increased the rapidity of their movements by a wonderful network of roads. This is clearly shown years later at Carrhae (*q.v.*) in 53 B.C. and Pharsalus (*q.v.*) in 48 B.C In the last mentioned battle Pompey's cavalry were disgracefully led, and even Julius Caesar, one of the great captains, never handled cavalry as it was handled by Alexander or Hannibal.

As a tactician Hannibal excelled, and his tactics were more flexible than those of Alexander because the organization of his army was far more fluid. He was a master of stratagem and surprise, but in siege craft he fell a long way behind the great Macedonian, otherwise Rome would have been his. At the battle of the Trebia (*q.v.*) in 218 B.C. he made full use of fire power to disorganize the Roman attack. Sempronius pushed back his centre, exposed his own wings to envelopment, and was charged by Mago in rear. At Lake Trasimenus (*q.v.*) the following year Flaminius was surprised in a defile, he was deprived of front, rear and

flanks, and his army was destroyed. The tactics Hannibal employed at the battle of Cannae (*q.v.*) in 216 B.C. have never ceased to be quoted; they were an improvement on those used at the Trebia, were somewhat similar to those of Miltiades at Marathon, and of Hindenburg at Tannenberg (*q.v.*) in 1914. Hannibal's grand tactical idea was that of the active defence. In place of forming a stable centre, as Alexander did, he formed a flexible one thrown forward in a half-moon formation so that when it was pushed back it would gain rigidity. Had it been a line, as was the case at Marathon, when forced to retire it might well have been broken. On the flanks of this central arch Hannibal hinged two flexible cavalry wings. The Romans forced back this living arch into a line, into a pocket, then Hasdrubal in command of the right cavalry wing wheeled round their left flank and charged them in rear. Their defeat was absolute. By 207 B.C. the Romans had learnt their lesson, and at the Metaurus (*q.v.*) it was Nero's attack on the rear of Hasdrubal's right flank which won him the day. Five years later at Zama Laelius and Massinissa fell on the rear of Hannibal's line and his defeat was total.

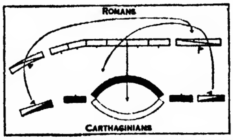

FIG. 5.—BATTLE OF CANNAE (216 B.C.), SHOWING TACTICS OF REAR ATTACK

Marius and Caesar.—After Zama the golden age of Roman tactics pales. There are many great battles, but mostly against ill-equipped barbarians. Technical rather than tactical perfection grows apace, and from an art war sinks into a trade. By the reforms of Marius (107 B.C.) the 30 maniples of the legion were converted into 10 cohorts, in all about 6,000 men. The distinction between *velites, hastati, principes* and *triarii* were abolished; the legionaries were all armed alike with a heavy javelin (*pilum*) and the short Spanish sword (*gladius*); the cavalry were removed from its organization, and the 3-line formation was replaced by a 2-line one, each of 5 cohorts at close distance. The veterans being in the first line. Such was the legion under Caesar, a cautious hard-headed tactician, a great administrator and a born diplomatist whose main contribution to tactics was his use of reserves. He solved the problem of how to sustain a frontal attack and simultaneously repulse an attack on flanks or rear. In his African war, on the open plain near Ruspina (46 B.C.), he was enveloped by the Numidian horse. Forming his troops into one line he ordered alternate cohorts to face about, burst through the Numidian ring with his flanking cohorts, and then charged the fragments. A similar manoeuvre was devised by Bouquet, about 1760, in his war with the red Indians in America. Caesar made great use of entrenched camps, converting them into movable fortresses to aid in victory, and to provide a rallying point in the event of defeat. As a strategist he fully grasped the value of an attack on his enemy's communications, and as a tactician he aimed at surprise, maintained an excellent system of scouting, but with the exception of his tactics at Ruspina he introduced no new formation of attack.

The Army of the Empire.—Under Augustus the changes which were taking form in the legion during the Civil Wars were brought to a head. The army of the republic was a burgess-militia; this had been largely replaced by professional soldiers and mercenaries. From this somewhat heterogeneous body of men Augustus created a standing army of 25 legions with cavalry attached. These were mainly quartered in permanent camps on the Rhine, Danube and Euphrates, and to them were frequently added large numbers of barbarian auxiliaries. For the protection of Italy Augustus raised ten praetorian cohorts of 1,000 men each. The total strength of the army under the early empire has been estimated at 300,000 men.

The main tendency of tactics now became defensive, the army by degrees approximating to a police force with two main duties, namely, internal security and frontier defence. The sword was largely discarded in preference for the spear, and so many missile weapons were added that hand-to-hand conflicts became the exception rather than the rule. The same forces were at work which modified the Hellenistic armies after the death of Alexander. Increase in wealth was followed by improvement in engineering and fortifications, with the result that artillery, both light and heavy, became the preponderating arm. At the siege of Massilia Caesar's soldiers had to protect themselves against projectiles with mantlets a foot thick. In A.D. 69, in a battle fought near Cremona between Vitellius and Vespasian, Tacitus tells us that the 15th Legion possessed a huge balista which would have destroyed the enemy's line had it not been damaged by two soldiers who risked their lives in the destruction of its mechanism. By the 4th century, according to Vegetius, each cohort was equipped with one catapult, and each century with one carro-balista which required 11 men to work it. Consequently the legion possessed an artillery train of ten "guns" and 60 "howitzers," that is approximately ten pieces to each 1,000 infantry, an exceedingly high proportion seeing that in Napoleon's time the number was generally three to 1,000, and even to-day it is seldom more than four or five to 1,000.

THE CHRISTIAN AGE

Glancing back over the history of war from the date of the Messenian War to the 4th century A.D., a period of 1,000 years, a similar tactical evolution can be traced in both the Grecian and Roman worlds. First we are confronted by an infantry period, the phalanx and early legion. Then contact with the Persian cavalry and Numidian horse points to the value of the rear attack. The art of war under Alexander, Hannibal and Scipio, all great cavalry and infantry leaders, suddenly advances by leaps and bounds, because they understand how to develop cavalry pressure from infantry resistance. Almost immediately after their death the art sinks to a low level, since this balance between the stable and mobile elements in tactics is not maintained. When the industrial epoch is entered, in the 3rd century B.C. in the case of the Hellenistic world, and in the 1st century B.C. in that of the Roman, artillery came to the fore, and though under able generals it is used offensively to develop the attack, more often than not it is used defensively to beat back an attacker. The will to clinch with an enemy is lost, and the result is that though military organization, especially in the Eastern empire, is of a high order, the loss in the spirit of the offensive deprives tactics of its soul, and the art of war enters its decadence.

Though it is obviously not possible to date the initiation, or close, of any tactical period throughout the Christian age, that is from about the close of the 4th century to present times, three great tactical cycles can be traced. The first is the cavalry cycle, which may be said to open with the battle of Adrianople (*q.v.*) in 378 B.C. and close with that of Agincourt (*q.v.*) in 1415. The second, the infantry cycle, though its origins are more indeterminable, next follows, reaches its apex under Frederick and Napoleon, and then steadily loses ground during the 19th century. In the World War of 1914–1918, it is definitely replaced by an artillery cycle, the origins of which reach back to the 16th century, and become plainly manifest during the Seven Years' War and the Napoleonic Wars. These three cycles will now be examined with the ultimate aim of forecasting the tactical tendencies of the age in which we live, and those of its immediate future.

THE CAVALRY CYCLE

The Late Roman and Early Gothic Cavalry.—Cavalry is pre-eminently the offensive arm, not because it can charge an infantry line, but because it can circumvent it, and either attack it in rear, or starve it into surrender by capturing its baggage train. Infantry can normally withstand the cavalry charge, consequently, when supported by cavalry, they, if efficiently armed, are invaluable as a "mobile fortress"—a pivot for cavalry manoeuvre, and if they in their turn are protected by artillery, which cannot protect itself, tactics flourish as a high art. After the battles of Carrhae (53 B.C.) and Pharsalus (48 B.C.) though there was a steady increase in Roman cavalry, there was also a steady deterioration in Roman infantry. Under Diocletian (245–313) cavalry rose from one-tenth to one-third of the infantry and numbered some 160,000; but this great mass of horse was with-

drawn from the infantry, and by being formed into a frontier guard lost its offensive spirit, and generally speaking was no match for the barbarian horsemen who in the 3rd century invaded the empire.

The decline in the value of the Roman infantry which was due to social reasons as well as military, left the defensive Roman cavalry without a base to meet the offensive Gothic horsemen whose first irruption took place in A.D. 248. Thirty years later, the emperor Valens met the Goths under Fritigern at Adrianople; his cavalry were routed and his legionaries surrounded and destroyed. In this battle the Romans are reputed to have lost 40,000 men. Though at times such as the battle of Taginae (*q.v.*) in 552, which resembles Crecy (*q.v.*) in 1346, and the battle of the Sarno (554), which resembles Cannae, such eminent generals as Narses succeed in wonderful combinations of infantry and cavalry, and of fire and shock tactics, the use of cavalry becomes more and more general. In 535, Belisarius in Africa won the decisive victory of Tricameron (*q.v.*) over the Vandals purely by cavalry, and a few years later we find that he has so little use for his infantry that he mounted them to serve as dragoons.

Armoured Cavalry.—In the Byzantine empire war continued to flourish as an art, but in the West all art disappeared, and as cavalry took to armour, which they did at the beginning of the 6th century, battles were replaced by skirmishes and campaigns by forays. Infantry now took little or no part in battles fought on ground over which armoured cavalry could move. In 814 a chronicler writes of Charlemagne and his host: "Then appeared the iron king, crowned with his iron helm . . . and round him and before him and behind him rode all his men armed as nearly like him as they could fashion themselves; so iron filled the fields and the ways, and the sun's rays were in every quarter reflected from iron. 'Iron, iron everywhere,' cried in their dismay the terrified citizens of Pavia."

The Cavalry Cycle was now reaching its zenith. At Hastings (*q.v.*) in 1066 and at Dyrrhachium (1081) the English axemen were powerless against armoured horsemen, and again this is proved at Bouvines (*q.v.*) in 1214. All that infantry can do is to remain behind entrenchments and use missile weapons. To the knight of the middle ages stability is no longer afforded by the infantry mass, but by the armour he wears, his mobility being provided by his horse. As long as he is not met by equally well mounted and armoured antagonists, this combination of mobility and stability proves irresistible in the melée, the one and only end of mediaeval tactics.

This self-contained stability of cavalry is most noticeable during the Crusades, for the Christian casualties are remarkably small. At the battle of Hazarth (1125) Baldwin's losses are only 24 men, whilst the Turks lose 2,000, at Jaffa (1191) 2 Crusaders are killed on the one side and 700 Turks on the other. The Crusaders' mobility is, however, restricted since the Turkish cavalry is for the most part unarmoured, and consequently extremely mobile. In order to overcome this difficulty, it was found necessary to dismount many knights and form them up on foot; in other words to establish a phalanx which not only offered the Turkish horsemen a target to hit at, but also a base of operations and harbour of refuge for the mounted knights. This change in tactical organization, which is fundamental, enabled the Crusaders to develop mobility from a protective base, not a static entrenched camp, but a movable body of men who could occupy and hold the positions won by the charge. Here we find the germs of a new infantry, for this procedure was copied in western Europe.

With the advent of plate armour in the 13th century mobility is sacrificed to protection; for though it is still possible to dismount the knight, so heavy has his armour become that when once dismounted he is unable to move over muddy or broken country. At the battle of Tagliacozzo (*q.v.*) in 1268, Conradin's Ghibelline knights are so heavily armoured that Charles of Anjou's cavalry, after exhausting them by repeated charges, roll them out of their saddles by seizing them by the shoulders. As armour increases in weight natural obstacles play a more and more important part in the battlefield. At Bannockburn (*q.v.*) in 1314 Bruce takes up his position behind a stream, and Edward II.'s knights are bogged just as in Flanders tanks are ditched 603 years later.

The Influence of the Bow.—A definite change in tactics now sets in. At Dupplin Muir (*q.v.*) in 1332 Baliol and Beaumont did not beat the earl of Mar by reckless charges, but by skilful weapon co-operation. The majority of their knights were dismounted and formed into a phalanx, the flanks of which were protected by archers, whilst only 40 mounted knights were kept in reserve for the decision. The earl of Mar charged the phalanx, which remained stable; his knights were immobilized by the archers on the flanks, and annihilated by Baliol's squadron. This battle is the birthday of a new era in tactics—the tactics of the bow, pike and lance combined. It forms the mould in which all the English operations of the Hundred Years War (*q.v.*) (1337–1453) were cast, a war which proved disastrous to the gallant but insubordinate chivalry of France, as Crécy (*q.v.*), Poitiers (*q.v.*) and Agincourt (*q.v.*) testify. From the battle of Poitiers onwards cavalry falls into a rapid decline, the French knights learn nothing, and as the bow and pike destroy them a new weapon arises in the crude bombards of the 14th century, which are about to revolutionize the whole art of war and introduce the infantry cycle.

THE INFANTRY CYCLE

The Influence of Gunpowder.—The rise of infantry was due as much to social as to military reasons. Feudalism which restricted their use was attacked by trade as well as by gunpowder. The increasing wealth of the 14th century had brought the cities into conflict with the Barons, and the result was not only a widespread series of Burgher wars but a steady increase in the infantry arm which was, however, powerless to attack the feudal strongholds until artillery came to its assistance. During the second half of the Hundred Years War this difficulty was overcome, for it was due to the artillery of Charles VII. more than to the visions of Joan of Arc that the English were ultimately driven out of France. This monarch provided himself with a train of artillery against which mediaeval fortifications proved a poor protection, and next we find cannon used in the open field, as happened at Formigny (*q.v.*) in 1450. To all intents and purposes this battle closed the Hundred Years War.

Meanwhile the hand gun, or Couleuvrine, was being turned to advantage by Ziska, in the Hussite Wars. For long it had been the custom to laager the baggage wagons in rear of the battles of knights. Ziska now turned this laager into a mobile fortress which he garrisoned with archers, cross-bowmen and hand gunners. Once the knights had shattered themselves against it, he would issue out with his cavalry and destroy them. Thus he won the battles of Deutschbrod (1422), Aussig (1426) and Taus (1431).

The Influence of Artillery.—Whilst the Swiss maintained their pikes and their phalangial formations which had proved so effective since the battle of Sempach (1386), during the second half of the 15th century such extraordinary progress was made in artillery that the wagon fortress (wagenberg) proved useless. The dismounted English and French knights once again took to horse, and as ordnance began to accompany infantry, more and more could foot soldiers work independently of cavalry and wagon forts. The close of the 15th century and the opening of the 16th saw the three arms we know to-day, namely, cavalry, artillery and infantry assuming tangible form. In France the infantry are poor on account of the strength of the feudal system. In Switzerland they become decadent as they refuse to change their shock tactics. In Spain they become highly efficient, a result of their struggle with the Moors, and under Gonzalo, who armed his foot with sword and buckler; against the Swiss and the German Landsknechts, in 1502, near Barletta, he repeated the Roman tactics of Pydna; for as Machiavelli says: "By the help of their bucklers and the agility of their bodies, having got under their pikes, and so near that they could come at them with their swords, the Spanish had the day with the slaughter of most of the Swisses."

The Development of the Musket.—As artillery forged ahead, and at the battle of Ravenna (*q.v.*) in 1512 broke away from the close support of infantry, and by taking the enemy in

flank played a decisive part in winning victory for the French under Gaston de Foix, a rapid evolution in the handgun set in. In 1520 the Spanish adopted the portable arquebus fork which stood them in good stead at Pavia in 1525. In this battle fought between the French under Francis I. and the Imperialists under Lannoy, we find a remarkable tactician, namely, the marquis de Pescaire drawing up a skirmishing line of 1,500 Basque arquibusiers who, according to Brantôme, "most wonderfully, though cruelly and villainously, discounted with much ease the power of the French cavalry."

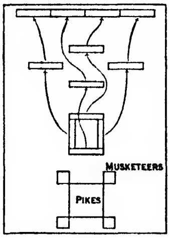

FIG. 6.—EVOLUTION OF THE SQUARE INTO THE LINE

In the wars between Charles V. and Francis I. the bow and cross-bow disappear. Artillery, owing to the development of fire-arms, is neglected, and seldom do we find more than one gun to 1,000 men. Fighting in extended order is developed, the musketeers rapidly growing in number. The French adopt the line as their tactical formation, the Spanish and Austrians maintain squares, normally of 3,000 men, 25 ranks deep. These squares possess a central corps of pikes, with bastions of musketeers at their corners. Later on, these solid squares are replaced by hollow ones, and at times their four sides manoeuvre as separate bodies. This is the beginning of the linear formation which definitely took form during the Thirty Years War.

Maurice of Nassau.—The 15th and 16th centuries were a period of transition from shock to fire tactics, or, broadly speaking, from the cavalry to the infantry cycles of war. The progress was remarkable in spite of opposition, for the new arms had as always to struggle for their existence. The elements of the new order had now been born, and two men, Maurice of Nassau and Gustavus Adolphus, shook them into form as Philip of Macedon had done nearly 2,000 years before their day. Maurice opened out the hollow square and placed its sides in "echequier." These sides he formed into regiments of two battalions each consisting of 500 men in ten ranks. The pikes were placed in the centre and the musketeers on the flanks; by a successive use of small bodies he wore his opponents down, and yet kept a reserve in hand. Having reorganized his infantry, he reduced the numerous calibres of the field guns to 24-, 12- and 6-pounders, and substituted iron balls for the hail shot hitherto used. He divided his artillery into two bodies, the heavy guns to introduce the battle, and the light to accompany the infantry and closely support them.

Gustavus Adolphus and the Thirty Years War.—Under Gustavus the evolution towards the line was rapid. He reduced the ranks of the musketeers to six, organized his army into brigades, each consisting of two regiments of two battalions each 1,000 strong. Each battalion was divided into eight companies each of which had 72 musketeers and 53 pikemen. He gave up the

FIG. 7.—FORMATION ADOPTED BY GUSTAVUS ADOLPHUS, WITH BATTALIONS DIVIDED INTO COMPANIES OF MUSKETEERS AND PIKEMEN

"echequier" formation and drew up his order of battle in line, the infantry in the centre and the cavalry on the flanks. In the Thirty Years War (*q.v.*) he used his artillery to break up the Imperialist squares by an overwhelming fire from a distance, and then charged home. Such tactics, combined with the flexibility of his troops in manoeuvre, won him his two great battles, namely, Breitenfeld (*q.v.*) in 1631, and Lützen (*q.v.*) in 1632. He never mastered, as Frederick the Great did, the tactics of artillery against an enemy who had taken up a strong defensive position such as that held by Wallenstein at Nuremberg in 1632. To do so a powerful howitzer was necessary, and failing this a mobile force of cavalry who could outflank the obstacle and attack the enemy, or his supply columns, in rear. After Gustavus's death we find this frequently taking place. Armour is discarded and the lance is laid aside, cavalry being armed with pistol and sword. Rocroi (*q.v.*) in 1643 was won by the French cavalry under Condé, and in England it was the cavalry of Cromwell which proved the decisive arm, since the infantry line found great difficulty in manoeuvring, and if its flanking cavalry were beaten it could be readily attacked in rear. The increased use of cavalry from Rocroi to the end of the 17th century marks the tactics of this period as one of manoeuvre; to fall upon the flank, or rear, of an enemy, is the controlling idea. Turenne was a master of these tactics, and for the first time since the opening of the infantry cycle the attack equipoised the defence. To assist cavalry mobility frontal fire is necessary, consequently skirmishers vanish and a rigid line is formed. The principal idea of Montecuccoli's order of battle is resistance, for as he says: "The secret of success is to have a solid body so firm and impenetrable that wherever it is, or wherever it may go, it shall bring the enemy to a stand like a mobile bastion, and shall be self-defensive." If once the enemy can be brought to a standstill, that is fixed by fire, the cavalry can manoeuvre. Marshal Luxemburg is a worthy disciple of Turenne. The battle of Fleurus (*q.v.*) in 1690 is a masterpiece in the art of manoeuvring, and so is that of Neerwinden (*q.v.*) in 1693.

The Solidification of Infantry.—The steady improvement in fire-arms, and the introduction of the socket bayonet by Vauban in 1687, reduced infantry to one type. The distinction between pikemen, musketeers, fusiliers and grenadiers was given up, and during the war of the Spanish Succession (1701–14) all foot were armed with the flintlock and the bayonet. Mobility was now reduced to a minimum, and battles are decided by order and cohesion followed by the cavalry charge. In this war Marlborough won most of his victories by cavalry, and when infantry played a prominent part, as at Malplaquet (*q.v.*) in 1709, the losses were appalling. The pike had vanished and had been replaced by the bullet, so that volleys of bullets in place of push of pikes now governed tactics.

Folard and Marshal Saxe.—It is a curious fact, yet one which cannot be disputed, that throughout the history of tactics when genius and leadership are wanting there has been a general tendency for military organization to return to its simplest form—the phalanx. This is what happened during the opening years of the 18th century, for though pikes had vanished, the phalangial idea is solidity, and as the English and German excel in this peculiarity the French suffered reverse after reverse. The crudeness of the phalangial order was clearly grasped by the chevalier de Folard who, in 1727–30, published a translation of Polybius fully sprinkled with his own ideas. Of this book Frederick the Great said: "Folard has buried diamonds in a rubbish-heap." This criticism is just, since the chevalier's ideas, though very confused, started a tactical argument of column versus line which only reached its solution in 1791. Folard attempted to establish a connection between fighting in line, column and in skirmishing order. He was supported by Maréchal de Saxe, who had not time, however, to put Folard's ideas into practice; in place he re-introduced fighting behind defensive posts, and made use of artillery to an extent unequalled since the days of Gustavus Adolphus. The result was that the Germans, Dutch and English suffered one defeat after another, since a phalangial army is incapable of maintaining its cohesion over obstructed ground.

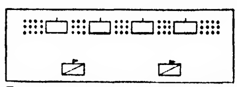

FIG. 8.—MARSHAL SAXE'S COMBINATION OF INFANTRY, LIGHT INFANTRY AND CAVALRY

Frederick the Great.—Frederick the Great now entered the tactical arena, and turned his attention to manoeuvre with a view to outflanking the phalanx. He divided his infantry into companies, established a definite drill, and formed his line of battle in three ranks. His cavalry were deprived of their fire-arms, and were taught to charge boot to boot and to rely on the *arme blanche*. So successful was he in their instruction, that there can

be no question that the cavalry of Zieten and Seydlitz were the most efficient since the days of Alexander. Though completely successful in his Silesian Wars (1740–42 and 1744–45), it is not until the Seven Years War (*q.v.*) (1756–63) that his genius was fully manifested. In the early battles of this war, the Austrians dispersed their guns along their entire front, and made all efforts on the part of the Prussians of no avail. At Lowositz (1756) Frederick's cavalry were repulsed by gun fire, and so also were his infantry at Prague (*q.v.*) in 1757 and Kolin (*q.v.*) in 1757. Frederick now saw that artillery was the superior arm, and proved it at Rossbach (*q.v.*) and at Leuthen (*q v*) in 1757. In these two battles the demoralization of the enemy was handed over from the infantry to the gunner. Not only did Frederick realize that artillery should prepare the infantry attack, but that it should search out the enemy where the terrain concealed him, consequently he increased his howitzers to one-third of his total guns, and massing them brought them against the defender's flank

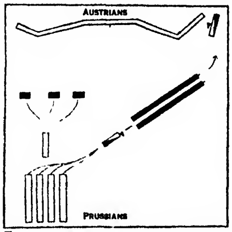

FIG 9.—BATTLE OF LEUTHEN (1757). SHOWING TACTICS OF FLANK ATTACK

Leuthen is probably the finest example of the Frederician tactics The Austrians, less well drilled, deployed, but he marched straight forward deploying his advanced guard only. Then wheeling the main body to the right he placed it at right angles to the enemy's left and deployed it in echelon in oblique order. The Austrians were fixed, since they were unable to manoeuvre. On their left flank, now in confusion through attempting to form a new front, Frederick converged the fire of *all* his guns. Under this fire his infantry advanced to the assault, and his cavalry manoeuvred on the rear of the enemy. At Torgau (*q.v.*) in 1760, one of his most daring battles, he separated his army, and whilst Zieten and his cavalry held the enemy's front, the bulk of his army took the Austrians completely in reverse.

Such were his battles, classical actions drawn from the study of classical history, for Leuthen was modelled on Leuctra (*q v.*). In brief, his system is expressed in his favourite maxim—"To bring one's own strength against the enemy's weakness." Like Alexander he refused one wing and assaulted with the other, the refused wing acting as a reserve to that part of the line not used for the shock. The assaulting wing consisted of an advanced guard, an artillery mass, an infantry mass and a cavalry mass. When the enemy stood in the open his guns smote them, and when he sought shelter by ground his howitzers pounded him to pieces.

Rise of Light Infantry.—As a gunner Frederick stands supreme, and further, he knew well the value of the cavalry charge and the infantry assault, but he never seems to have grasped the value of a well-trained light infantry for protective duties, and for preparing the act of distraction, for only towards the end of his reign did he raise a few battalions of fusiliers In spite of this neglect, the times demanded a change towards infantry flexibility. Folard had advocated it, Saxe had proved it at Lauffeld (1747), Henry Lloyd wrote about it in his "History of the Seven Years War," and so had Guibert, the most far-sighted tactician of his day in his "General Essay on Tactics" (1751). In 1702 the French had raised several "Compagnies Franches" under the duc de Bellisle, and in 1725 the English raised the Black Watch, a form of irregular police "for the protection of the country against robbers " It was, however, during the Seven Years War that the new infantry order took form In Europe Moratz, Trenk, Nadasty and Frankini raised bands of Croats, Pandours and other ruffians who fought as independent riflemen, and in America, Bouquet, Rogers, Howe and Montgomery demonstrated their extreme value when well led and trained against the red Indians. After this war, all these lessons were lost sight of. The glamour of Frederick's great battles blinded the military eye; soldiers sought his secret in his drill and not in his ideas, and prepared for themselves a rude awakening in the wars of the American Rebellion and the French Revolution.

Whilst backwoodsmen and redskins were picking off the British red-coats, and whilst Simcoe, Tarleton and Ferguson were striving their utmost to counter them by raising light infantry, the maréchal de Broglie, in 1778, at the camp of Vaussieux carried out experiments in line and column, showing that the evolutions of the first were heavy and difficult, and of the second flexible and speedy. Mesnil Durand advocated massive columns, Guibert battalion columns. Then came the French Revolution, all tactical shibboleths were cast to the winds; cohesion disappeared, and man took to natural fighting, that is skirmishing, and though the Revolutionary armies, utterly lacking in discipline were frequently beaten, in 1794 an A.D.C. of the duke of York was compelled to acknowledge that "No mobbed fox was ever more put to it to make his escape than we were." Though in their first campaigns the French looked upon columns solely as reservoirs for skirmishers, it soon became apparent that skirmishers should be used for the act of distraction, and that columns should be used for the act of decision, artillery being employed to co-operate with the skirmishers. Thus was re-established the tactics of the successive employment of arms

Napoleon.—Whilst in Austria and Prussia the art of drill was mistaken for the art of war, the greatest military genius of modern time, but certainly not the greatest tactician, emerged out of the chaos of the Revolution to astonish the world As a grand tactician and a strategist Napoleon stands supreme, and it may be due to this that as a minor tactician he left much to be desired. Sometimes he broke his enemy's centre, as was the case at Rivoli (1797), Marengo (1800), Friedland (1807) and at Ligny (1815), but normally he preferred a flank, or, if possible, a rear attack, for he understood clearly that the rear was the decisive point. His grand tactics consisted in engaging as few troops as possible, using them up completely without reinforcing them, and meanwhile holding in hand his main body for the decisive blow, which when once delivered was normally followed by an annihilating cavalry pursuit. "It is by turning the enemy, by attacking his flank, that battles are won." So said Napoleon, and he always when possible attempted it, as at Castiglione (*q.v.*) in 1796, Ulm and Austerlitz (*q.v.*) in 1805, Jena (*q v*) in 1806, Eylau (*q.v.*) in 1807 and Wagram (*q.v*) in 1809. If he did not succeed in a full attack on the flank, he contented himself with an outflanking movement These are battles of intellect rather than of muscle in spite of their slaughter and destruction, yet had he paid more attention to minor tactics his battles would have been even more intellectual

In his Italian campaigns of 1796–97 we find full use made of line, column and skirmishers. At Lonato and Castiglione, the French work in battalion columns at deploying intervals, the columns being of double companies covered by skirmishers. At Rivoli (*q v.*) it is much the same. At the crossing of the Tagliamento (1797) demi-brigades are used, the centre battalion being deployed, and the flanking battalions kept in double company columns with skirmishers in front. Such a formation enabled considerable frontal fire to be delivered without uncovering the flanks to cavalry attack. After 1800 we find a change, the act of distraction passing more and more from the infantry to the artillery. It was not that the French infantry were falling off in value, as has frequently been stated, for probably as late as 1812 they were equal to those of 1796. It was because Napoleon, like Frederick, had begun to realize that artillery is the superior arm. Even at Castiglione and Rivoli he massed the few guns he had. When guns are allotted to divisions as they were to Augereau's corps at Eylau and to Ney's at Friedland the infantry are repulsed But after Aspern (*q.v.*) in 1809 Napoleon fully grasped Frederick's system, and increased his guns from two to three to each 1,000 infantry. He also created a central artillery reserve of 126 guns, and allotted a reserve artillery to each *corps d'armée*. From Wagram (1809) onwards "it is the number of pieces rather

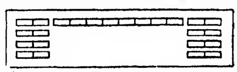

FIG. 10—FORMATION OF AN ATTACK OF A DEMI-BRIGADE

than that of battalions which henceforth serves as the measure of the relative strength of armies." Thus writes Napoleon: "The better the infantry, the more one must husband it and support it with good batteries. . . . The invention of powder has changed the nature of war: missile weapons are now become the principal ones: it is by fire and not by shock that battles are decided to-day. . . . The power of infantry lies in its fire. In siege warfare, as in the open field, it is the gun which plays the chief part; it has effected a complete revolution. *It is with artillery that war is made.*" Curious as it may seem, it was Napoleon's lack of appreciation of the value of the howitzer which caused him heavy casualties at the battle of Borodino (*q.v.*) in 1812, and decisive defeat at that of Waterloo (*q.v.*) in 1815.

Wellington.—In Napoleon's early campaigns we find the active defence playing an important part, for example at Rivoli and Arcola (1796), but once the emperor became the man of destiny, the reincarnation of Alexander, of necessity the offensive replaced this more cautious system of waging war. Yet fate must have it otherwise, for once he had decided that the gun was the decisive weapon, as he did after Aspern, he was immediately confronted by a general—Wellington—who made the active defence the backbone of his tactics. The method adopted by the Iron Duke and his generals was simplicity itself, and it invariably succeeded. It consisted in selecting a good covered position behind which the main force of infantry was deployed, and in front of which was extended a line of skirmishers trained on the system taught by Sir John Moore at his camp at Shorncliffe in 1803–1805. The French advanced in columns, company behind company, covered by skirmishers, and were met by musket, rifle and artillery fire, and severely mauled. When they neared their objective, the English rose from behind their cover, fired a volley, rushed forward lapping round the columns, and charging them in front and both flanks. The battle of Busaco in 1810 is probably the most perfect example of these tactics. At Albuera (*q.v.*) in 1811 the English attacked a mass of columns on a hill with the same result. Again were these tactics repeated with decisive effect at Salamanca (*q.v.*) in 1812 and finally at Waterloo.

The amazing thing was that Napoleon never seems to have grasped how easily they could be defeated. Frederick had been equally ignorant of the solution at the opening of the Seven Years' War, but once the Austrians began to use ground as cover against fire, he at once increased the number of his howitzers, and literally blew them out of their positions. Had Napoleon realized the power of the howitzer, and had the third of his artillery been howitzers, there is little doubt that at Waterloo he would have been able to demoralize the main force of Wellington's army who were sheltered from his cannon balls and grape shot, and so have paved the way for the advance of his squadrons and infantry columns. It is one of those enigmas of tactics that with all his genius he could not see this very simple solution as old as the battle of Hastings (*q.v.*) and beyond.

The Influence of the Rifle.—The 50 years which followed the battle of Waterloo are tactically most instructive. Over 20 years of devastating war, of battles, sieges and naval actions, of attacks and retreats, and manoeuvres taught the armies of Europe nothing, and from the military point of view Napoleon might as well have never been born. No sooner had the emperor been incarcerated in St. Helena than the rigid school of war, the men of the hoplite mind, took over control. Nevertheless in spite of their ponderous ideas the industrial revolution swept on. Invention followed invention, and amongst these were two of supreme tactical importance, namely, the percussion cap invented in 1814, and the cylindro-conoidal bullet invented in 1824.

The rifle had been long known, but hitherto all rifles and muskets had been fired by a flint and steel, and in rainy weather frequently misfired. The percussion cap signed the death warrant of the cavalry charge, and the conoidal bullet revolutionized artillery tactics. In 1839 a percussion musket was issued to the British infantry, and in 1851 they were equipped with the Minié rifle, a weapon with an effective range of 1,000 yards. In 1815 cavalry, artillery and infantry were in close contact, and operated by the general in chief as easily as a platoon is to-day. The guns were frequently placed in front of the infantry, and the cavalry close behind them. All this was changed by the rifle. The cavalry can no longer attack infantry, unless completely broken. The guns have to retire well in rear of the infantry, and as the range of the rifle is increased so is the distance between them and the infantry they are supporting. Thus the old battle order, which in idea had changed but slightly since the days of Gustavus Adolphus, was completely thrown out of joint. To operate an army as Wellington did at Waterloo was impossible; to render its separated parts co-operative demanded intelligence and not merely a powerful voice. The Prussians seeing the difficulty attempted to overcome it by replacing the general by an army fashioned like a clock, which once wound up was expected to tick out victory. The English maintained their fox-hunting generals, and the French, contemptuous of others, since they had produced one of the greatest geniuses in history, shrouded their ignorance in the glamour of his fame.

Tactics from 1849 to 1870.—The middle of the century ushered in a series of wars which lasted for 20 years. During this long period tactics underwent a profound change; the gun again and again asserted its superiority, yet the leaders of armies still maintained the supremacy of infantry. They could not see that as each campaign ended infantry had become more and more a supplement to artillery action. The battle of Temesvar, in 1849, was but a repetition of Ocaña in 1809, for artillery not only accomplished the act of demoralization, but brought both of these battles to a decisive issue. The war in the Crimea was largely an artillery war, mainly so on account of Sevastopol. True, the French massed their artillery as Napoleon had done, but between the British and the Russians the old and somewhat stale contest of line versus column was once again fought out, because the Russians still believed in shock by weight of numbers, which never takes place, and the British in deployment in order to develop fire power which seems obvious, but which apparently is not so to a semi-oriental, since the Russians repeated their tactics in 1878.

In 1859 rifled guns were issued to the French army, and this same year Napoleon III., emulating his uncle, decided on a war against Austria in Italy. The Austrian infantry were the better armed, as the Lorenz muzzle-loader was superior to the French Minié rifle. To compensate for their inferior rifle the French made extensive use of skirmishers, the Austrians normally remaining stationary. The broken nature of the ground favoured these tactics, as happened at Solferino (*q.v.*) in 1859. When Marshal Niel's firing line began to waver he brought up his reserves, and "the bayonet," as he writes in his report, apparently to please the emperor, "recovered everything that had been lost by the fire-fighting." His enemy, the Austrians, however, showed no initiative. They believed in the methodical battle as recommended by the Germans, that is, a gradual nourishing of the fighting-line until the enemy's strength is used up; only then would they attack him with their last reserves. What actually happened was that the nourishing of their firing line starved their reserves to death, so that when the decision was signalled the reserves had volatilized. The French learnt little from this war, and never troubled to reflect on the causes of their successes. The Austrians, however, learnt "that the employment of artillery *en masse*, when it is to take general part in the action, must be made from the very beginning, and the infantry attack must really be the one to bring about the decision."

In 1859 the Austrian tactics were of a defensive nature, in 1866 they were diametrically opposite, that is they were offensive, and with these tactics they decisively defeated the Italians under La Marmora, at Custozza (*q.v.*) in 1866, though it should be remembered that their enemy had lost all power of taking the initiative. In Bohemia it was otherwise, for the solid masses of Austrians who, almost unprotected by skirmishers, attempted to rush the Prussians armed with the needle gun, were decimated. In the Prussian army, however, the employment of the arms in co-operation had been neglected. Their general staff had studied the French infantry tactics of 1859, but their artillery tactics had

been overlooked. They considered that the bulk of the guns should be held in reserve for the final act of disruption, and that distraction could best be attained by a methodical infantry fight. One-third of the guns were to support the attack, one-third to reinforce it, and the remaining third to be held back in reserve. Thus was the battle of Trautenau fought on June 27, 1866, and that of Nachod, on the same day, was fought almost entirely without artillery. At Skalitz, the next day, it was much the same. After this battle the Prussians suddenly woke up to the value of artillery, and at Koniggrätz (*q.v.*) the methodical attack was replaced by the manoeuvre battle, and artillery in place of being held in reserve for some problematical decision was brought forward, as was notably the case in the II Army.

In the American Civil War (*q.v.*) (1861–65) the most prominent tactical lessons were the power of the rifle on the defence, and the ever increasing use of entrenchments to enhance this power. The gun now became definitely the backbone of the defence, and as the Americans still possessed many smooth-bore guns the discharge of case-shot on the attackers was frequently devastating. Nevertheless the defence was devoid of strategical results, and lack of strategy on the part of the Southern Armies ended the war.

In 1870 the Prussians possessed the superior gun and the French the superior rifle. The French having watched the failure of the Austrian offensives in 1866 determined to base their tactics on the defensive. Moltke, who was a believer in defensive tactics, was thus compelled to assume the offensive. At Spicheren (Aug. 6, 1870) the Prussian tactics were methodical since reinforcements came forward gradually. At Gravelotte (*q.v.*) (Aug. 18) the battle was one of manoeuvre prepared by an overwhelming artillery fire. Sedan (*q.v*) (Sept. 1) was essentially an artillery battle, and the result of a finely executed strategical manoeuvre. In all the battles of this war, whenever the infantry fought in successive efforts, and were predominantly employed, the result was "the complete dissolution of the body of troops engaged, divisions as well as corps, and extraordinary losses" Breech-loader met breech-loader, and unless the attacker could by artillery fire adequately break down the defender, the attack was repulsed unless it was delivered against a flank

To all who possessed the slightest tactical perception it was apparent that the leading lesson of this war was that artillery had definitely become the stable element in the fight. Other lessons were: That in certain circumstances the defender can be so completely broken by gun fire that the infantry attack can be dispensed with; that infantry armed with the breech-loading rifle need pay no longer any attention to cavalry; that, to initiate an attack, all the artillery must be brought into line as soon as possible, and must not only crush the enemy's artillery but prepare the infantry advance by a lengthy bombardment Yet, in spite of this, as the war showed, fronts had become inviolable, for, throughout the war, neither the French nor the Germans succeeded in taking a single position by a frontal attack The infantry breech-loading phalanx was unbreakable, and cavalry though they could turn it were incapable of attacking it in flank or rear.

Tactical Theories, 1875–1900.—In 1870–71 the French lost battle after battle, yet they came out of the war as oblivious to its lessons as did Frederick's mule after its tenth campaign. From 1875 to 1900 the French regulations maintain the complex system of firing line, supports, local reserves and reserves in echelon. The infantry regulations do not even mention artillery, which is supposed to have completed its task by the time the infantry attack is launched. The power of fire was recognized, and in order to develop it to the full, about 1895, whole battalions were moved forward in single rank without intervals between the men, and were called "skirmishing lines." Behind these walls of rifle fire "decisive attacks," whatever these might mean, were to be launched forward by brigades and divisions in mass. In an official report written in 1875 we read: "Troops massed in column, or in line in close order, can no longer manoeuvre, fight or even remain in position under fire." Twenty years later this lesson having been forgotten, the regulations extol dense formation, not for marching and manoeuvring only, but for the attack itself. "Troupes de choc," "Masse de manoeuvre" and such like metaphysical terms were invented. It was considered that well-led troops must overcome all obstacles. A veritable spell fell not only upon the army of France but on all the armies of Europe

The South African War, 1899–1902.—The South African War did little to dispel this hallucination. Artillery action was negligible, and infantry formations, which at first were dense, were thinned out into a line of men at from ten to 50 paces between individuals. To command such a line was impossible. To those who could read tactics aright the outstanding lesson was the power of the rifle on the defensive. At Modder River (1899) the British had 3,000 men on a front of 7,000yd.; at Colenso in the same year 4,500 on a front of 13,000yd, and at Magersfontein (1899) 5,000 on a similar frontage These fronts could not be pierced. Again, as had been learnt in 1870, frontal attacks even against weakly held positions were no longer possible. The war ended through the gradual attrition of the Boers.

The Russo-Japanese War, 1904–1905.—The Russo-Japanese War (*q v.*) did more than confirm the lessons of the South African War, for it demonstrated clearly the uselessness of the frontal attack, the power of the rifle and machine gun on the defensive, and that, as Napoleon had said 100 years earlier, "it is with artillery that war is made." In broken ground the Japanese made use of moderately thick skirmishing lines, but in open country they had the wisdom to thin them out to from five to ten paces between men, the men being rushed forward in twenties 20 to 30 paces at the time. The Russian fire tactics were execrable, nevertheless the Japanese assault generally failed, and to avoid casualties night operations became prevalent.

This war is remarkable in that to-day we can see in it a small edition of the World War of ten years later. The machine gun when efficiently handled by trained men, which was not the case in the South African War, added enormously to the defence. The artillery was driven further and further back by the bullet, until the gunners were compelled to seek cover by ground and cease firing over their sights. Trenches appeared everywhere, not a single battlefield remained untrenched. Whenever it was possible these trenches were protected by wire entanglements Frontal attacks, save as fixing operations, were altogether out of the question, and at each great battle, and notably so at the Yalu (1904), Liao-Yang (1904) and Mukden (1905), it was a Japanese threat of envelopment carried out by infantry and artillery, since cavalry had lost all offensive power, which compelled the Russians to retire.

The main lesson, however, was one which had been steadily maturing since Frederick massed his guns at Leuthen· it was the ever growing power of artillery Maj. J. M. Home of the British army, and attached to the Russian army, saw this clearly, and in one of his official reports may be read the following:—"The great impression made on my mind by all I saw is that artillery is now the decisive arm and that all other arms are auxiliary to it. The importance of artillery cannot be too strongly insisted upon, for, other things being equal, the side which has the best artillery will always win. . . . So strongly am I convinced of the immense importance of artillery that it seems almost a question for deliberate consideration whether artillery should not be largely increased even at the expense of the other arms. . . . With the extraordinary development of artillery it begins to appear as though infantry fire action cannot usefully be employed at ranges beyond 600yd., as beyond that distance the hostile guns ought to be able to prevent infantry from using their rifles" The battles of the Balkan War of 1912 in no way contradicted this statement. The war in Manchuria was brought to an end in 1905 not through tactical or strategical action, but by revolution and attrition. Both sides were virtually worn out, and Russia was threatened by rebellion and disaster.

The Tactics of the Unlimited Offensive.—The lessons of the wars in South Africa and Manchuria were entirely lost on the general staffs of European armies. The enormous power of modern weapons on the defensive was completely overlooked. A new school, the Moral School of War, rose in the ascendent. In France Col. de Grandmaison was its high prophet; his theory of war was

implicity itself. It was: "A man seized by the throat and who is occupied in guarding himself cannot attack you in flank or in ear." Therefore rush on the enemy with all forces united and overwhelm him, or in his own words "Frapper fort, frapper tous ensemble." The French "Conduite des Grandes Unités" of 1913 was based on this doctrine. It was pointed out that all past French disasters had been due to the defensive! That after the South African War the theory of the inviolability of fronts had been propounded, and had been given the lie direct in the Russo-Japanese War! That all could be overthrown by the offensive; that he enemy's position must be taken with the bayonet, and that when once the battle is launched it must be pushed forward egardless of cost to the last man!

The doctrine laid down in the German training manuals is identical. Cavalry must be used in mass: "No squadron should wait till it is attacked; it should always attack first." "Artillery should enter into action almost like one blow, in masses." "The infantry of the main body should simultaneously make a united attack." And again: "The infantry should cultivate its natural propensity for the offensive. All its actions must be dominated by this one thought: *Forward, upon the enemy cost what it may.*" Such was the frenzy which smote French and German tactics like pestilence. The art of war was to be replaced by a dog-fight, each side was to fly at its antagonist's throat and shake him to pieces. The whole process was so irrational as to be mad. Two years before the South African War, and 18 years before the World War, M. Bloch, a Polish banker, had seen this clearly. He said that the future of war would not be fighting but famine, "not the slaying of men but the bankruptcy of nations. . . . Everybody will be entrenched in the next war. It will be a great war of entrenchments. The spade will be as indispensable to a soldier as his rifle. . . . All wars will of necessity partake of the character of siege operations. . . . Your soldiers may fight as they please; the ultimate decision is in the hands of *famine.*" Had the general staffs of European armies been as clear-sighted as M. Bloch, there would have been no question as to the nature of the tactics of the next war.

THE ARTILLERY CYCLE

Return to the Phalanx and the Legion, 1914.—The picture of the World War as painted by M. Bloch was exact because his colours were the tactics of the military schools, and his perspective the outlook of a war artist and not of a war artisan. His was not so much a remarkable forecast as a remarkable synthesis derived from a remarkable analysis of the military theories of his day. The South African War showed that his deductions were well founded, and the war in Manchuria proved definitely that he was right, yet so obsessed were soldiers by the metaphysical power with which in their theories they had endowed infantry, that they had become completely hypnotized by the glint of their bayonets. The war might have been very different from the above picture if the means of waging it had been changed, or even if the weapons it was fought with had been revalued and differently proportioned.

The controlling factor was, however, neither "famine" nor "the unlimited offensive," it was the industrial revolution, and it mattered not what was done or said by the soldier during peace time, in war the military factors of this revolution would out. Soldiers, blinded as they were, could not see this; they could not see that science and industry were the controlling forces in the approaching war. They talked of *morale,* but forgot "fear"; they advocated offensive action but neglected defensive power. They studied history not to discover truth but to prove their doctrines. They could not see that since cavalry had lost its power, tactics as an art had been thrown out of joint, and had retrogressed to the phalangial order. Further, they were oblivious to the fact that when phalanx met phalanx there would be no assault—for the assault was as dead as the charge. To hit at the decisive point had now become so difficult as to be tactically almost impossible. The act of annihilation had vanished, the acts of dislocation and disruption had vanished, all that was left of the battle were the acts of contact, of approach and of partial distraction. Therefore the war must be a war of attrition, of maximum slaughter and minimum profit; therefore M. Bloch was right.

When war was declared, once again did the phalanx meet the legion. The German phalanx was 250m. long, and the French legion was distributed in front of its left wing on a little more than half this frontage. The French grand tactics were absurd, namely, to attack the front of the phalanx, an operation which has nearly always ended in failure. Those of the Germans were simplicity itself, namely, to lap round the left flank of the French legion and attack it in rear. They failed because the right wing of the phalanx was itself attacked in flank at the battle of the Marne (*q.v.*) in 1914. At the battle of Tannenberg (*q.v.*) in 1914 the Russians were routed because they were attacked in rear; and at the battle of Megiddo (*q.v.*) in 1918 the Turks were routed for a similar reason. The major tactical problem on every front was the rear attack, and to frustrate such an attack each front in turn crystallized out into a trench line, as M. Bloch had predicted.

The Supremacy of Static Artillery, 1915–1917.—To break these entrenched fronts cavalry were useless, they could not charge them; infantry were useless, they could not assault them—though in 1914 and 1915 such attempts were foolishly made. More than 100 hundred years had gone by since Napoleon had said: "It is with artillery that war is made." No one had heeded him, no single soldier of eminence had definitely proclaimed that the gun was the superior arm. Since the battle of Ravenna, fought in 1512, whenever a supreme military genius had arisen the gun had proved the superior weapon on the battlefield. Gustavus proved this, Frederick proved this, Napoleon proved this, and Moltke proved this, yet on the death of each of these great captains the sprouting artillery cycle had been trodden into the dust by the officially minded soldier. At length, in 1915, 400 years after Ravenna, no professional feet were big enough to stop its growth.

In the spring of 1915 the long delayed artillery cycle opened with the battle of Neuve Chapelle (*q.v.*), a brilliantly conceived attack but one on so restricted a front that it was doomed to failure. In the autumn of this year, surprise was set aside and replaced by method, method ultimately depending on shell production. Little by little it was discovered that it was no longer the infantry who attacked but the artillery; that it was first necessary to destroy the defences of the enemy before attempting to capture them. The supreme tactical lesson of 1915 was: "Artillery conquers and infantry occupies." Tactics were thus reduced to a matter of push of pikes, or rather—push of shells.

In 1916 infantry had become so immobile, that a rolling barrage was introduced. Not only was it necessary to bombard an enemy's position for days on end, but to establish a wall of shells in front of the infantry, a shield of fire which slowly moved forward in front of the infantry. This wall replaced the old infantry firing line, the infantry supporting it. The infantry attack was as dead as the infantry assault. All infantry could now do was to carry out the approach and the contact, and when the limit of gun range was reached, the approach ceased. Nevertheless the battle of the Somme (*q.v.*) in 1916 cost the British 475,000 casualties, and the battle of Verdun (*q.v.*) in 1916 cost the French 350,000 and the Germans 500,000. In 1917 this elephantiasis of shell fire reached its zenith in the third battle of Ypres (*q.v.*). To prepare this battle the British massed 120,000 gunners, who in the initial bombardment, lasting 19 days, fired 4,283,000 shells, weighing 107,000 tons and costing £22,000,000. This battle lasted approximately three and a half months, and each square mile of mud gained cost the British army 8,222 casualties.

The Supremacy of Mobile Artillery, 1917–1918.—Thus far the artillery cycle had proved a grotesque failure, the reasons being that grand tactics were at fault. In all these battles the central idea was to use artillery to blow a hole through the enemy's defences in order to facilitate the advance of the infantry, who were in their turn to facilitate the advance of the cavalry. It was this conception of tactical action and not the gun which was to blame, since if such penetration were effected, this in itself would not render infantry and cavalry invulnerable to the bullet, and

the bullet was the father of the trench. The problem was not to advance infantry and cavalry, but to advance the guns, and this demanded that their crews and teams should be rendered bullet proof. The problem was to produce a mobile self-protective gun. Once produced it could advance and blow the enemy back, and behind it the infantry could follow to occupy ground, and the cavalry to collect prisoners. In brief, as the artillery barrage had replaced the old infantry firing line, the problem now was how to replace this barrage by a moving line of guns and howitzers. This problem was solved by the tank which definitely established the artillery cycle.

Return to the 1914 Model.—The armies which fought in 1918 were very different from the armies which entered the war in 1914. Cavalry and infantry had steadily dwindled in importance, and artillery had rapidly come to the fore; nevertheless so conservative is the spirit of the soldier that in 1919, in spite of vastly increased machine gun power, all armies as quickly as possible reverted to the 1914 model Lethal and non-lethal chemicals were prohibited, tanks, guns and aircraft were reduced in numbers on wholesale lines, and infantry, who were impotent during the war, were once again proclaimed the predominant arm. In the British Field Service Regulations of 1924 it was stated: "Infantry is the arm which in the end wins battles. . . . The rifle and the bayonet are the infantryman's chief weapons The battle can be won in the last resort only by means of these weapons." Tactically the war had been fought in vain; nevertheless in spite of the war, and in spite of the conservatism of soldiers, science and industry will win through. The artillery cycle has come to stay for its period, and there can be no possible doubt that armies will be mechanized.

Lessons of the Three Cycles.—As this is so, the question arises: Can past tactics assist the tacticians of to-day to predict the tactics and army organization of to-morrow? A brief summary of what happened during the last 1,500 years will show that this question can be answered in the affirmative. In the cavalry cycle war as an art virtually disappears because mobility is founded on no stable base. There is no possibility of holding an enemy, consequently movements are chaotic, and it is only when the infantry cycle is well advanced that cavalry tactics once again become an art, movements being replaced by manoeuvres. No sooner has this high order of tactics been established, than the increased power of the musket reduces the power of cavalry, and as cavalry loses power to manoeuvre, infantry becomes paralytic Infantry can hold infantry, but they have no stable base to manoeuvre from. To make good this deficiency artillery is established as the base of action, and infantry tactics assume a high order. Manoeuvre is again established, but as infantry can move but slowly tactical manoeuvre is largely replaced by strategical manoeuvre, which under Napoleon assumes its highest form. Artillery now becomes so powerful, that infantry, following in the footsteps of cavalry, can no longer develop movement from their artillery base. Artillery then becomes the predominant arm, and as guns cannot move in face of infantry fire, and as infantry can no longer manoeuvre under gun fire, in 1915 the result is static warfare. To reinstate manoeuvre, that is to develop offensive mobility from a protective stable base, the tank, or mobile armoured gun, is introduced. The base of action of the tank is the static gun In fact the tank bears the same tactical relationship to the horse-drawn gun as the cavalry once did to the infantry.

To-day this inherent defect which characterized the classical artillery cycle can be overcome once it is realized that it is now possible to make a radical change in the element of movement. Hitherto it has been muscular (human or animal); to-day, based as it is on petrol and oil power, it can be made mechanical Consequently two great categories of artillery can be established, namely, mobile offensive and mobile protective artillery; the second forming the base of action of the first, the second holding and the first hitting the enemy. Thus true manoeuvre is once again rendered possible.

This change in the element of movement will strongly influence the element of protection. Since the initiation of the infantry cycle, protection has in nature been mainly indirect, but in the last war, the full advent of the artillery cycle, it became direct, and, as happened in the classical artillery cycle, it took the form of entrenchments, the symbol and soul of the passive defence. Mechanical power now enables the soldier to replace direct protection as afforded by the trench by direct protection as afforded by armour, as happened in the cavalry cycle, which followed the classical artillery cycle. The influence of this on the last tactical element, namely, weapon-power, will also be most marked, because not only will shock weapons disappear, but the smaller missile-throwing weapons also.

The combination of these remodelled tactical elements will re-establish tactics as an art, and the anatomy of battle will once again take its full form. The decisive point of attack will once again become the rear of the enemy's army. The approach will be made rapidly not only by road but across country, consequently the nature of strategy will be changed Hitherto strategy has been based on roads and railways, it has been linear. Linear movements demand column formations, but as the artillery cycle develops, area warfare will replace linear warfare, and fronts may be anywhere. The old deployed fronts which protect the rear (the decisive point) in approach and in attack will vanish, and will be replaced by a mobile elastic square within which the old rear will be established; the rear will in fact become the centre The attack will be divided into the act of demoralization which is more and more likely to be waged against the command of the enemy, the brains of his army, than against the nerves of his men. And the act of decision will aim more at restricting the mobility of the enemy's main force than in physical destruction of its organization Once the enemy is held, that is, mobility is denied to him, the act of annihilation will take place

TAEL (tāl). The tael is a Chinese weight of rather more than an ounce. It is usually applied to silver, and as the Chinese internal currency is based upon silver, the tael has become, for many important purposes, the monetary unit of China. This statement, however, is by itself incomplete and requires some explanation and qualification

The original coinage of China consisted of copper coins known as li or cash. These are minted with a hole through the middle, and as each one is worth only $\frac{1}{10}$ of a penny or so, it was customary to string a whole bundle together. Again nominally, 1,000 cash equal one tael of silver, but this ratio naturally varies with the relative price of copper and silver, and owing to this and also to the confusion into which the Chinese coinage has fallen, the present ratio is rather greater than 1,000.

As already said, the tael represents a definite weight of silver. It is not in internal circulation—for, as shown later, all silver coinage takes the form of dollars of one sort or another—but is used for many important purposes as money of account. Silver is imported in the form of ingots and recast into the form of shoes. This work demands the highest degree of craftmanship, and the shoes are in themselves a work of art. They vary slightly from centre to centre in their silver content, but those of the finest silver are known as "sycee." These shoes are weighed in taels.

Unfortunately the tael is not a constant weight, nor does it con-

sist of fineness of silver. There are many taels in existence, all varying in both these important respects. The most important taels are now described:—

(1) **The Haikwan Tael.**—This weighs about 583·3 grains of silver, 1,000 fine. All customs duties are payable in this tael, and as a result, it forms the unit in which foreign trade and exchange are carried on. The Chinese rate of exchange is always quoted in London in pence to the Haikwan tael, and as a rule foreign bills of exchange are reckoned in and payable in taels (unless drawn in sterling or other foreign currency). This tael thus forms the link between China and abroad, and therefore is the most important of all.

(2) **The Kuping Tael.**—This weighs about 573·9 grains of silver, 1,000 fine. It is the unit in which all Government taxes, other than customs duties, are payable.

(3) **The Shanghai Tael.**—This weighs about 545·25 grains of silver, 980 fine. It is the unit in which northern China trade is carried on, but to further confuse the issue, it is ordained by custom that 98 Shanghai taels weight of silver is full payment for a debt of 100 Shanghai taels in money.

The internal silver currency of China takes the form of silver dollars. The earliest of these was the Carolus dollar. This is now disappearing. Next came the Mexican dollar, which, owing to its high reputation for purity, has enjoyed a wide circulation in many parts of the world. The former Chinese empire at the end of the 19th century tried to coin and introduce its own silver dollar, called the Dragon dollar, while just before the World War, the new Chinese republic introduced a new dollar. The weakness of all Chinese money is that each province has its own mint, which works according to its own rules, with the result that continued debasement has undermined public confidence. The same objection applies to the many note issues.

It is impossible to describe the chaotic condition that has arisen during the troubles of post-war years. All that can be said is that, before China can have a national currency, she must establish a stable national Government. Meanwhile the use of silver taels and silver dollars is well understood by bankers and traders, and provides a satisfactory medium for the conduct of trade. (*See* also CURRENCY.) (N. E. C.)

TAENIA, in architecture, the uppermost member of the architrave (*q.v.*) of one of the classic orders. (*See* ORDER.) In the Tuscan and Doric orders it is a projecting fillet, decorated, in the Doric order, with the regulae (*q.v.*) and guttae (*q.v.*). In the Ionic, Corinthian and Composite orders it is enriched with one or more mouldings.

TAFARI MAKONNEN, RAS: *see* MAKONNEN, RAS TAFARI.

TAFFETA, a term strictly denoting a light, thin and plain texture of silk possessing a high sheen or gloss and finished in a manner that imparts to it the "rustle" or "scroop" peculiar to certain types of closely-woven, plain silk textures produced from spun silk yarn. The warp and weft may be of corresponding denier or counts, approximately, while the number of warp threads and picks per inch may also correspond. Taffeta is sometimes embellished with a very small brocade or "float" figuring of warp or weft, and may either be woven from skein-dyed yarn, or else piece-dyed after weaving. Some qualities of taffeta fabrics are artificially "loaded" (*i.e.,* weighted) with metallic salts, and are therefore more liable to split or crack when creased or folded. It is used chiefly for dress, millinery and similar purposes.

The word "taffeta," however, is now applied as a description of many other varieties of fabrics produced from silk, wool, cotton and combinations of these materials. Chiffon taffeta is of a softer texture and finish than that of ordinary taffeta. One variety of taffeta is produced from a silk warp and Botany wool weft; while another variety, described as "wool taffeta," is woven entirely of fine wool yarn both for warp and weft, which makes a fine and close texture of light weight, with a smooth surface. Some varieties of taffeta are produced from a cotton warp and fine Botany weft, whilst others are woven entirely with two-fold cotton yarn of fine counts, and finished with a stiff "finish" to simulate the "scroop" peculiar to silk fabrics.

TAFILÁLT or **TAFILET** (*i.e.,* "The Country of the Filáli," as its inhabitants are called, because descended from the Arabian tribe of Hilál, settled here in the 11th century), important oasis of the Moroccan Sahara, ten days' journey south of Fez, across the Atlas. It is celebrated for its dates, to the successful cultivation of which, soon after the arrival of an ancestor of the reigning dynasty of Morocco (hence called the Filáli Sharifs, *i.e.,* descendants of Mohammed) *c.* A.D. 1250, this dynasty owes its rise.

Tafilált is a succession of ksurs (fortified villages) and palm groves which correspond to the zone irrigated by the Wad Ziz, and stretch over a length of about 50 kilometres. It comprises seven districts, Wad-Ifli, Seffalat, Ghorfa, Sifa, Beni-Mohammed, Tani-jut, and Wad-Malah; the largest centre is Bu-Am, an important market. The sedentary natives, numbering about 150,000, are exploited by the Aït-Atta nomads, and live in poverty on their palm groves. The industry is the tanning of goat-skins to obtain *filali* leather, which has a great reputation. The *takaut* (*Tamarix articulata*) yields gall for tanning. Since 1648 it has been the custom of Moorish sultans to despatch superfluous sons and daughters to Tafilált. In Ifli, the central portion, formerly existed the town of Sigilmasa, founded by Miknása Berbers in 757 B.C. It was on the direct caravan route from the Niger to Tangier, and attained a considerable degree of prosperity.

The first European to visit Tafilált was Rene Caillie (1828), the next Gerhard Rohlfs (1864). A later visit to the oasis by W. B. Harris is described in his book *Tafilet* (London, 1895).

TAFT, LORADO (1860–), American sculptor, was born at Elmwood, Ill., on April 29, 1860. He graduated at the University of Illinois in 1879, and from 1880 to 1883 studied in the École des Beaux Arts, Paris. In 1886 he became instructor at the Art institute, Chicago, lecturing there, at the Chicago university, and elsewhere in the United States. He was elected to the National Academy in 1911; from 1914 to 1917 he was director of the American Federation of Art. Among his works, in addition to much portraiture, are: "Sleep of the Flowers" and "Awakening of the Flowers," both made for the Columbian exposition; "Despair" (1898); "Solitude of the Soul" (1900) and "Fountain of the Lakes" (1903); "Black Hawk" (1912), figure of an American Indian at Oregon (Ill.); Thatcher memorial fountain (1918) at Denver (Colo.); and "The Fountain of Time" (1920) at Chicago. In 1920 he published *Modern Tendencies in Sculpture;* and in 1924 a new edition of *The History of American Sculpture,* an exhaustive and authoritative work first issued in 1903.

TAFT, WILLIAM HOWARD (1857–), the 27th president and tenth chief justice of the United States, was born in Cincinnati, O., on Sept. 15, 1857. His father, Alphonse Taft, was attorney general in President Grant's cabinet (1876–1877) and minister to Austria (1882–4) and to Russia (1884–5). William Howard Taft graduated second (salutatorian) in his class at Yale college in 1878, and at the Law school of Cincinnati college, in 1880, dividing the first prize for scholarship. In the same year he was admitted to the Ohio bar. In 1881 he was appointed assistant prosecuting attorney of Hamilton county (in which Cincinnati is situated), but resigned in 1882 on being appointed U.S. collector of internal revenue for the first district of Ohio. In 1883 he returned to the law. From 1885 to 1887 he served as assistant solicitor of Hamilton county, and in the latter year was appointed judge of the superior court of Ohio, to fill a vacancy, being elected in the next year. In 1890, he was appointed solicitor-general of the United States by President Harrison. In 1892 he was appointed U.S. circuit judge for the sixth circuit. From 1896–1900 he also served as professor and dean of the law department of the University of Cincinnati.

Governor of Philippines.—In 1900 he was appointed by President McKinley to the presidency of the Philippine commission. He served as such from March 13, 1900 to Feb. 1, 1904, becoming governor *ex officio* on the establishment of civil government, on July 4, 1901 (*see* PHILIPPINE ISLANDS). The delicate matter of confiscated church lands was arranged by Taft in a personal interview with Pope Leo XIII., in the summer of 1902. The pope sent a special delegate to appraise the

lands, and the sum of $7,239,000 was paid for them in Dec. 1903.

Secretary of War.—In Feb. 1904, Taft returned to the United States to become secretary of war. In Sept. 1906, on the downfall of the Cuban Government and the intervention of the United States he took temporary charge of affairs in that island (Sept.–Oct.). In the next year (March–April) he inspected the Panama canal and also visited Cuba and Porto Rico. He again visited the Philippines to open the first legislative assembly (Oct. 16, 1907). On this tour he visited Japan, and on Oct. 2, at Tokyo, made a speech which had an important effect in quieting the apprehensions of the Japanese on the score of the treatment of their people on the Pacific coast. While secretary of war, Taft entirely reorganized the work of carrying on the construction of the Panama canal, and selected Col George W Goethals, whom President Roosevelt put in entire charge of the work. From that moment the enterprise assumed a new vigour, the work was completed and was opened to traffic in 1913.

President.—In 1908 Taft was favoured by President Roosevelt as his successor, and in the November election, was victorious over William Jennings Bryan, the Democratic nominee, by a popular majority of 1,269,900 votes (Taft, 7,679,006; Bryan, 6,409,106) and by a majority of 159 votes in the electoral college In accordance with his pre-election pledge, he called the Congress to meet in extra session on March 15, 1909, to revise the tariff. The final bill known as the Payne-Aldrich Act was approved by the president on Aug 5, 1909, although in many respects it was not the measure he desired. The income of the Government under the Dingley tariff had proved inadequate to meet its current expenses, the estimated deficit for the fiscal year ending July 1, 1909, being $100,000,000 He therefore recommended to the Congress the adoption of resolutions to amend the Constitution by expressly granting Congress power to levy an income tax without apportionment among the several States. For the purpose of meeting the immediately anticipated deficiency in the revenues, he recommended the adoption of a provision in the Tariff Bill imposing an annual special excise tax upon corporations organized for profit, measured by a percentage on their net incomes. Pursuant to these recommendations a proposed amendment to the Constitution was passed by both Houses of Congress, afterwards ratified by the requisite number of the States, and became the 16th amendment, and there was included in the Payne-Aldrich Act a provision imposing the proposed annual special excise tax upon corporations, measured by 1% of their net incomes

Payne-Aldrich Tariff Act.—While the Payne-Aldrich Act was much criticized, because it failed to reduce duties on imports to the extent expected, yet it marked a distinct step towards a lower scale of import duties, and opened the door to the free exchange of commerce with the Philippines. By the enactment of the maximum and minimum tariff provisions, it placed a powerful weapon in the hands of the American Government for the protection of American commerce against unduly discriminatory practices by foreign Governments. It also, for the first time in American history, provided for the establishment of a tariff board to study the questions which lie at the foundation of the protective system

While Congress was considering the Tariff Bill, the president called upon the heads of the departments of Government to prepare, in advance of the usual time, their estimates for the fiscal year ending June 30, 1911, admonishing them to reduce expenses wherever it could be done These estimates were then considered by the president and cabinet, and for the first time in American history, a comprehensive budget was prepared. As a result of these efforts, a cut was made of about $55,000,000 in the estimates for the fiscal years 1910 and 1911. In June 1910, the Congress granted the president's request for an appropriation to enable him to employ competent persons to study the methods of transacting the public business of the executive departments and other Government establishments, and to recommend such legislation as might be necessary to carry into effect changes found to be desirable that could not be accomplished by executive action alone. President Taft caused a commission to be organized, and as a result of its studies, sent to Congress four special messages transmitting the reports of the commission, dealing with particular subjects, pointing out defects in the organization and conduct of the business and changes that might be made advantageously.

Federal Budget Urged.—In his message of Jan. 17, 1912, the president called attention to the fact that the United States was the only great nation whose Government was operated without a budget, and recommended the adoption of an annual budget. Nothing was done by Congress in these matters, but many, if not most, of the improvements in the organization and conduct of the administrative branch of the Government which have been adopted in more recent years were first formulated and recommended by President Taft. He also recommended to Congress the enactment of amendments to the interstate commerce law, the establishment of a postal savings bank system, the enactment of laws giving the interstate commerce commission the power to determine upon the uniform construction of appliances used by railway trainmen in the operation of trains and to intervene and investigate the reasonableness of a proposed increase in railway rates before they became effective; of amendments making the Employer's Liability Act more easy to enforce, of laws carrying out with intelligent discrimination the principle of conserving the national resources; the establishment of a national health bureau, requiring publicity of campaign contributions; regulating the procedure of Federal courts concerning the issue of injunctions; and readjusting the regulations concerning postage of second class mail matter Most of these recommendations were embodied in laws passed by the Congress By executive order, the President placed the positions of secretaries in the diplomatic service in much the same position as those in the consular service, and introduced into both the principle of appointment for reasons of ascertained fitness and promotion by merit

Arbitration Treaties.—In 1910 and 1911, President Taft negotiated with the Governments of France and Great Britain identical treaties, signed on Aug 3, 1913, intended to be models for a series of treaties providing firstly, for the arbitration of all differences which might arise between the parties which it was not possible to adjust by diplomacy, and which were justiciable in their nature, and secondly, for the creation of a joint high commission of inquiry, to which should be referred for impartial investigation, any justiciable controversy between the parties before submission to arbitration, and also any other controversy, even if the parties were not agreed that it fell within the scope of the first article, the report of such commission not to be regarded as a decision on the questions submitted The first of these provisions embodied in effect the agreement reached in the treaty between the United States and France of Feb. 6, 1928. The second furnished a model for the treaties negotiated by Secretary Bryan in 1914, known as the Bryan Conciliation Treaties. Together, they represented a greater advance in provisions for the peaceful settlement of international controversy than any the world had known. The U S Senate qualified its approval by such extensive reservations, that the president withdrew the treaties from further consideration. In 1910, President Taft initiated negotiations with the British Government for the establishment of a reciprocal trade agreement between the United States and the Dominion of Canada. Instead of embodying the desired tariff changes in the formal shape of a treaty, it was agreed that the Governments of the two countries should use their utmost efforts to bring about such changes by concurrent legislation at Washington and Ottawa. It was further agreed that a considerable list of articles produced in both countries should be reciprocally free. As to another group, common rates of duties upon importation from either country into the other were fixed. The proposed legislation was, however, defeated in the dominion parliament, and the effort failed.

As the construction of the Panama canal approached completion, a bill was introduced in Congress to provide for its operation and for the government of the Canal Zone. Taft was of the opinion that as the United States had built the canal at its own

expense, it was entitled to permit the use of the canal by American merchant ships without payment of tolls. Great Britain claimed that this would be a violation of the Hay-Pauncefote Treaty. While not admitting the contention, the president expressed his willingness to arbitrate the question. The bill, as passed, embodied the president's views, but the next Congress modified the act by removing the discrimination.

Other Events in Administration.—President Taft's administration was characterized by a systematic and vigorous enforcement of the anti-trust laws. The decisions by the U.S. Supreme Court in 1911, of the prosecutions which had been initiated by President Roosevelt against the Standard Oil trust and the American Tobacco combination, and which were argued in the Supreme Court by Attorney General Wickersham, gave an authoritative interpretation to the act, which was at once put into effect by the Department of Justice, and for the first time after the enactment of the law in 1890, a careful, systematic effort was made by the Government to enforce its provisions. Both the oil trust and the tobacco combination were dissolved in such manner as to restore healthy competition in those industries without destruction of the value of their securities held by innocent parties. A large number of combinations in restraint of trade were either put an end to by judicial process, or voluntarily desisted from a continuance of the practices which had been adjudged to be illegal.

During Taft's administration, many vacancies occurred in the Federal judiciary. He was called upon to appoint six justices of the Supreme Court, including a chief justice. On the death of Chief Justice Fuller, in 1910, President Taft nominated as his successor, Associate Justice Edward D. White, a Democrat, a former Confederate soldier, and a Roman Catholic—a nomination which was confirmed by the Senate at once.

Conservation of the natural resources of the nation was one of the subjects which had greatly occupied the attention of the president and his administration. While Taft was in full sympathy with the objects of this policy, he did not approve of some of the means adopted by that administration. In making up his cabinet, he did not include James R. Garfield, secretary of the interior under President Roosevelt, and on Jan. 7, 1910, he dispensed with the services of Gifford Pinchot, the forester. These men, with a number of other adherents of Roosevelt, initiated a campaign against President Taft, based upon the representation that he was opposed to the conservation policy of Roosevelt. Their first attack upon his Administration was directed against Secretary Ballinger, who had succeeded Garfield. A complaint by L. R. Glavis, an agent in the land office in the Department of the Interior, of Ballinger's action with regard to certain coal land entries in Alaska known as the Cunningham claims, which President Taft on investigation held to be unfounded, and which led to the dismissal of Glavis from the service, gave rise to a Congressional investigation into the conduct of the Interior department by Ballinger. After prolonged hearings a report was made by the committee exonerating secretary Ballinger, but failing to win the confidence of the public, he resigned in the spring of 1911.

In the regular Republican convention at Chicago, the total number of delegates summoned was 1,078, with 540 necessary to a choice. Taft had 561 votes on the first and only ballot and was declared the nominee. Roosevelt and his progressive supporters, claiming that part of his delegates had been stolen through the action of a hostile committee, refused to accept the results of the convention, organized one of their own, known as the "Bull Moose" convention, nominated Roosevelt for the presidency, and carried on an aggressive campaign against Taft, which resulted in splitting the Republican vote in almost every State, and thus electing Woodrow Wilson, the Democratic nominee, as president. The electoral vote was: for Wilson, 435, Roosevelt, 88 and Taft, 8. The popular vote, however (Wilson, 6,285,-214; Roosevelt, 4,126,020; Taft, 3,483,922), showed a much closer contest. This Party schism served in large measure to obscure the merits of President Taft's administration.

Subsequent Career.—On retiring from the presidency in 1913, Taft became Kent professor of law at Yale, but devoted much time to lecture engagements. In the same year he was elected president of the American Bar Association, and in 1914 first president of the American Institute of Jurisprudence, organized to improve law and its administration. Taft was an active promoter of the League to Enforce Peace, but after America's entrance into the World War, he supported the Administration, taking the ground that victory was necessary to the attainment of lasting peace. In 1918, he was appointed by President Wilson a member of the national war labour board for arbitrating labour disputes. In 1919, he endorsed the Peace Treaty of Versailles, regarding its most important part to be the Covenant of the League of Nations. He spoke throughout the country on behalf of the league urging reservations if these would secure ratification. He supported Warren G. Harding, the Republican candidate for president in 1920. On the death of Chief Justice White, on June 30, 1921, he was appointed by President Harding chief justice of the United States.

Taft is the author of *Popular Government; its Essence, its Performance, and its Perils* (1913); *The Anti-Trust Act and the Supreme Court* (1914); *The United States and Peace* (1914); *Ethics in Service*, Yale lectures (1915); *Our Chief Magistrate and His Powers*, Columbia lectures (1916) and *The Presidency: its Duties, its Powers, its Opportunities and its Limitations*, lectures at the University of Virginia (1916). (G. W. Wi.)

TAGALOG, a tribe of eastern Mindanao, in the Philippines, formerly head-hunters, particularly on occasions of the deaths of prominent tribesmen; they made wood or stone figures to accommodate the souls of deceased persons (*Relacion de las Islas Philipinas*, anon., *c.* 1595). They are now Christians, but very superstitious. They practice circumcision, make excellent soldiers, sailors, boat-builders, fishermen and artisans; they are good agriculturalists, cultivating rice on irrigated terraces; they are fond of cock-fighting, and women have equality with men.

See Sawyer, *Inhabitants of the Philippines* (1900).

TAGANROG, a Russian seaport in the North Caucasian area, in 47° 12′ N., 38° 50′ E., on the north shore of the Gulf of Taganrog, which is a north-eastern arm of the Sea of Azov. It is connected by rail with the north, and also with Rostov-on-Don to the east. It has three harbours, and several grain warehouses. The anchorage is 5 to 6 ft. at the loading pier, but there is no regular port accommodation, and the usual anchorage ground, 18 to 20 ft. deep, is 25 to 30 m. from Taganrog. It is icebound for three or four months in winter, and the depth of water near the town may be diminished as much as 7 ft. by a prolonged east wind. Its imports include fruits (dried and fresh), nuts, oil, wine, coffee, tobacco, woollen goods, cement and manufactured iron goods, and its exports grains, macaroni, linseed, rape seed, caviare, wool, butter and oilcake. Many of the exports are brought by lighters or local steamers from Rostov-on-Don. The town has a fishing industry and manufactures metal goods (especially instruments) and paper. A colony was founded on the site by Pisan merchants in the 13th century, but was destroyed by the Mongols. Later it was occupied by the Turks. Peter the Great attempted to gain possession of the promontory, but it was not annexed to Russia until 1769. Its commercial importance dates from the construction of the railway linking it with Kharkov. The Anglo-French fleet bombarded and partially destroyed the town in 1855.

TAGES, a minor Etruscan deity, the grandson of Jupiter, and founder of the art of divination in Etruria. According to the story, during the ploughing of a field near Tarquinii a being of boyish appearance sprang out of the furrow. The shouts of the ploughman (Tarchon) brought to the spot all the people of Etruria, whom the boy proceeded to instruct in the art of divination. Having done this, he suddenly disappeared. His instructions were for some time handed down orally, but were subsequently committed to writing, and formed the twelve books of Tages, containing a complete system of Etruscan lore.

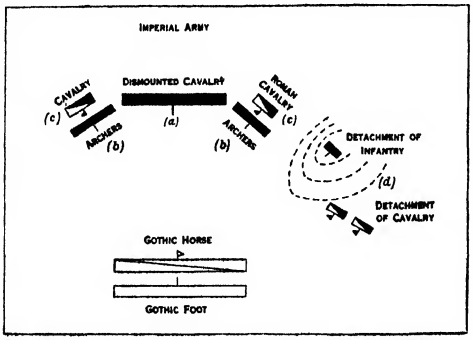
TAGINAE, BATTLE OF (A.D. 552). The battle of Taginae was fought in July 552. It terminated the Gothic Wars of the Emperor Justinian, and was won over the Gothic King

Baduila by the eunuch Narses, a general who in ability rivalled the great Belisarius, his contemporary. Taginae is situated below the Apennines near modern Gubbio. Narses had crossed the head of the valley of the Chiascio when Baduila arrived and seized its main outlet. The Goth ranged the whole of his horsemen in front, his infantry, mostly archers, he drew up in second line. His aim was to ride down the imperial army in one terrific charge.

Belisarius had noted the weakness in the Gothic tactics, namely, that there was no co-operation between lance and bow. Narses



BATTLE OF TAGINAE (JULY, A D 552), WON BY NARSES, GENERAL OF THE EMPEROR JUSTINIAN, OVER BADUILA, KING OF THE GOTHS

now aimed at this co-operation, but in a novel form which closely resembles the combined tactics made use of by Edward III. at Créçy. He dismounted his cavalry (*Foederati*) and formed a phalanx 8,000 strong, on the wings of which he drew up 8,000 archers with their outer flanks thrown forward In rear of these he posted his Roman cavalry to combine fire and shock. His left flank he rested on a small hill, which he occupied by a force of infantry and at the foot of which he deployed a few squadrons of cavalry.

At noon Baduila, ignoring the archers, suddenly charged his enemy's centre, expecting to overwhelm it, for infantry he held in contempt. He was met by a tremendous converging fire of arrows which slew and dismounted hundreds of his knights After several assaults he clinched with the imperial centre—its protective base of action—which held him firm whilst his flanks were plied with arrows At length, exhausted, the Gothic horsemen broke back, when immediately Narses launched his mounted squadrons driving them in confusion on to their infantry which were ridden over. The victory was complete.

TAGLIACOZZO, a town of the Abruzzi, Italy, in the province of Aquila, 56 m. by rail E.N E. of Rome, and 10 m W. of Avezzano. Pop. (1921) 7,823, town; 8,961, commune. It lies 2,428 ft. above sea-level, at the mouth of the deep ravine of the Imele. It contains several old churches, notably S. Francesco, with a fine rose window in the façade, and mediaeval houses. The palace, built at the end of the 14th century by the Orsini, is fine, with interesting paintings in the interior. At the end of 1268 a battle took place here between Conradin of Hohenstaufen and Charles of Anjou, which resulted in the defeat of Conradin.

TAGORE, SIR RABINDRANATH (1861–), Indian poet and author, was born in Calcutta on May 6, 1861, the youngest son of Maharshi Devendranath and grandson of Prince Dwarkanath Tagore. After a private education in India he was sent to England in 1877 to study law, but soon returned to India, and while still quite young commenced writing for Bengali periodicals. In 1901 he established the famous Shantiniketan, a school at Bolpur, 93 m. from Calcutta, which developed into an important educational institution conducted on unconventional lines, and now approaches an international university. In 1913 Tagore was awarded the Nobel prize for literature, and utilized the amount, £8,000, for the up-keep of his school. He has visited Europe on several occasions and travelled also in Japan and the United States. He accepted a knighthood in 1915, but in 1919 resigned it as a protest against the methods adopted for the repression of disturbances in the Punjab. In later years, however, he offered no objection to the use of this title. Tagore is interested in politics only in so far as it concerns the deeper life of India, and he desires that the nationalist movement should consider social reforms before political freedom. By his abundant writings, which are permeated by a sense of the beauty of the universe, by a love of children and of simplicity, and by a consciousness of God, Tagore has done much to interpret for the West the more serious reflections of the people of Bengal.

His most important works which have been translated into English are *Gitanjali* (1913); *The Crescent Moon* (1913); *Chitra* (1914); *The Post-Office* (1914); *The Gardener* (1914); *One Hundred Poems of Kabir* (1915); *Fruit-Gathering* (1916); *Stray Bird* (1916); *The Lover's Gift and Crossing* (1917); *Nationalism* (1917); *Lectures on Personality* (1917); *My Reminiscences* (1917); *The Parrot's Training* (1918); *The Home and the World* (1919); *Sakuntala* (1920); *Red Oleanders* (1925). *See* E. Thompson: *R Tagore, Poet and Dramatist* (Oxford, 1926).

TAGUS, the longest river of the Iberian peninsula. Its length is 565 m., of which 192 are on or within the frontier of Portugal, and the area of its basin is about 31,850 sq m The basin is comparatively narrow, and the Tagus, like the other rivers of the Iberian tableland, generally flows in a rather confined valley, often at the bottom of a rocky gorge, as at Toledo and Alcántara, below the general level of the adjacent country. The river rises on the western slope of the Muela de San Juan (5,225 ft.), a mountain which forms part of the Sierra de Albarracin, 88 m. E of Madrid. Thence the Tagus flows at first north-westwards, but, after receiving the Gallo on the right, it flows west, and then south-west or west-south-west, which is its general direction for the rest of its course. Regular river navigation begins only at Abrantes, a few miles below which the Tagus is greatly widened by receiving on its right bank the impetuous Zezere from the Serra da Estrella. Passing Santarem, the highest point to which the tide ascends, and the limit of navigation for large sailing vessels and steamers, the river divides below Salvaterra into two arms which enclose a deltaic formation, a low tract of marshy alluvium known as the Lezirias, traversed by several minor channels Both branches terminate in a broad tidal lake immediately above Lisbon (*q.v.*). The Tagus estuary, though partly blocked by a bar of sand, is one of the chief harbours of south-western Europe.

TAHITI, the largest and most important of the French Society islands in the Pacific ocean, in 17° 38′ S., 149° 30′ W Area about 600 sq m. and population (1924), 7,145. The chief town is Papeete, with 4,601 inhabitants, of whom 2,126 are French. For an account of the physical structure, climate, flora and fauna and general geography *see* PACIFIC ISLANDS.

History.—The discovery and early exploration of the Society islands is treated under that heading In 1788, when Lieutenant Bligh, in the "Bounty," visited Tahiti, the leading chief was Pomare, whose family had been pre-eminent in the island for more than a century. Aided by 16 of the "Bounty" mutineers, and armed with guns procured from Bligh and a Swedish vessel, Pomare greatly strengthened his power and brought to a successful close a long struggle with Eimeo.

The attempt at colonization by the Spaniards in 1774 was followed by the settlement of 30 persons brought, in 1797, by the missionary ship "Duff." Though befriended by Pomare I. (who lived till 1805), they had many difficulties, especially from the constant wars, and at length they fled with Pomare II. to Eimeo and ultimately to New South Wales, returning in 1812, when Pomare renounced heathenism. In 1815 he regained his power in Tahiti. For a time the missionaries made good progress—a printing press was established (1817), and coffee, cotton and

SCENES IN TAHITI

1. Tahitian pearl diver in outrigged canoe. These natives become very proficient in the art of managing their tiny craft. A delicate sense of balance is a necessary qualification
2. Inland view of Tahiti showing conical peaks, coconut palms and luxuriant undergrowth characteristic of the island's landscapes

763, ed., Arnold, London, 1879); and his prowess is depicted on the Bayeux tapestry. The statement of Wace in the *Roman de Rou,* 3rd part, v 8035–62, ed Andresen (Heilbronn, 1879), that Taillefer went before the Norman army singing of Charlemagne and of Roland and the vassals who died at Roncevaux, has been considered important in demonstrating the existence of a comparatively early tradition and song of Roland

See W. Spatz, *Die Schlacht von Hastings* (Berlin, 1896); Freeman, *History of the Norman Conquest.*

TAILOR, one who cuts out and makes clothes (Fr. *tailleur,* from *tailler,* to cut, Lat. *talea,* a thin rod, a cutting for planting). Formerly the tailor, or *cissor,* made apparel for both men and women, and not merely outer garments, but also articles of linen and the padding and lining of armour—whence the style "Taylors and Linen Armourers" applied to the Merchant Taylors Company of the City of London in their earliest charters But the word is now generally limited to those who make the outer (cloth) garments for men, and less frequently for women, though a phrase such as "shirt-tailor" is occasionally met with In modern usage, too, it commonly has the implication that the garments are made to the order, and to the measure, of the individual purchaser, as opposed to ready-made clothing, which means articles of apparel manufactured in large quantities in a series of stock or standard sizes, such that any purchaser may expect to find among them one that will fit him with more or less accuracy. The clothing trade was originally confined to goods of the poorest grades, but it has come, both in Great Britain and in America, to include articles of good, though not of the first, quality. It probably first came into existence at seaport towns, where, to meet the convenience of sailors returning from long voyages and requiring their wardrobes to be replenished at short notice, the "outfitters" kept stocks of ready-made garments on sale; but it made no considerable progress until after the middle of the 19th century, when the introduction of the sewing-machine brought about the possibility of manufacturing in large quantities Its development was attended with gradually increasing subdivision of labour and, to a large extent, with the disappearance of the tailor as a skilled craftsman

The first step was for a garment, such as a coat, to be completed by the joint efforts of a family Then followed the "task system," which in America was the result of the influx of Russian Jews that began about 1875. Under it a team of three men, with a "presser" and a girl to sew on the buttons, divided the work between them. Payment was made by the "task," *i.e*, a specified number of garments, the money being divided between the members of the team in certain proportions. Often several teams would be run by a contractor, who naturally selected the cheapest workshops he could find and packed them as full of workers as possible; and when through stress of competition he had to accept lower prices the plan he adopted was to increase the number of garments to a task, leaving the pay unaltered The result was the introduction of many of the worst features of the "sweating system," the workers having to work excessively long hours in order to finish the task, which in some cases meant as many as 20 coats a day. In the "factory" or "Boston" system the subdivision is still more minute, and as many as 100 persons may be concerned in the production of one coat. The amount of tailoring skill required in a worker is even further reduced, but the premises come under the regulation of the factory laws The factory system has also cheapened production in a legitimate way, because it has enabled mechanical power for driving sewing-machines, and also expensive labour-saving machinery, to be introduced to an extent not practicable in small shops. (*See* CLOTHIERS; *Wholesale.*)

TAIN, royal and police burgh and parish, county of Ross and Cromarty, Scotland. Pop (1921) 1,551. It is within 1 m. of Dornoch Firth, 25½ m. N E. of Dingwall by the L.M.S R. The name is from the Icelandic *thing,* "assembly" or "court." The industries include distilling and woollen manufactures, and the town is a market and distributing centre. In the centre of the town is a picturesque tower, once a gaol Duthac (locally called Duthus), a saint of the 11th century, is believed to have been a native, and the ruined chapel near the station is supposed to have been his shrine. To the collegiate church of St. Duthus, a Decorated building, founded by James III. in 1471, James IV. made several pilgrimages in penance for his father's death. The building was used as the parish church till 1815, when it fell into disrepair, but it was restored between 1871 and 1876. It has monuments to Patrick Hamilton, the martyr, and Thomas Hog (1628–1692), the Scottish divine. Three and a half miles S.E. are the remains of the Early English abbey of Fearn, founded at Edderton in 1230 by Farquhar, 1st earl of Ross, and transferred hither in 1338. Patrick Hamilton became titular abbot in 1517, and after his martyrdom the abbey was added to the bishopric of Ross.

TAINE, HIPPOLYTE ADOLPHE (1828–1893), French critic and historian, the son of Jean Baptiste Taine, an attorney, was born at Vouziers on April 21, 1828. J. B. Taine died on Sept. 8, 1840, leaving a moderate competence to his widow, his two daughters, and his son Taine was educated at the Collège Bourbon, where he formed lifelong friendships with Prévost-Paradol, for many years his most intimate friend, Planat, the future "Marcelin" of the *Vie Parisienne,* and Cornélis de Witt, who introduced him to Guizot when the latter returned from England in 1846. Taine passed from the Collège Bourbon to the École Normale, but in 1851 he was refused the fellowship in philosophy which was universally regarded as his due Nevertheless the minister of public instruction appointed him to a professorship at Toulon, which he exchanged for one at Nevers. But he refused to express explicit approval of the coup d'état of Dec. 27, 1851. Consequently he was removed to an inferior post; next year saw a further step downward, and he accordingly applied for, and received, indefinite leave of absence. In a few months his two dissertations, *De personis Platonicis* and the essay on La Fontaine's fables were finished, and May 30, 1853 he took his doctor's degree. This was the last act of his university career; his life as a man of letters was now to begin.

No sooner had he deposited his dissertations at the Sorbonne than he began to write an essay on Livy for one of the competitions set by the Academy. Here again the moral tendency of his work excited lively opposition, and after much discussion the competition was postponed till 1855; Taine toned down some of the censured passages, and the work was crowned by the Academy in 1855. In the beginning of 1854 Taine, after six years of uninterrupted effort, broke down and was obliged to rest. The year 1854 was an important one in the life of Taine His enforced leisure, the necessity of mixing with his fellow-men, and of travelling, tore him from his cloistered existence and brought him into more direct contact with reality. He lived with his mother in the Isle Saint-Louis, and now he once more associated with his old friends, Planat, Prévost-Paradol and About He made the acquaintance of Renan, and through Renan that of Sainte-Beuve, and he renewed friendly relations with M Havet, who for three months had been his teacher at the École Normale. These years (1855–56) were Taine's periods of greatest activity and happiness in production. In 1855 he published seventeen articles in the *Revue de l'Instruction publique,* and twenty in 1856 on the most diverse subjects, ranging from Menander to Macaulay. From 1857 onwards he was a regular contributor to the *Journal des Débats.*

But he was seeking a larger field. In January 1856 his history of English literature was announced, and in 1855–56 he published in the *Revue de l'Instruction publique* a series of articles on the French philosophers of the 19th century, which appeared in a volume at the beginning of 1857. In this volume he energetically attacked the principles which underlie the philosophy of Victor Cousin and his school. The book closes with the sketch of a system in which the methods of the exact sciences are applied to psychological and metaphysical research. The work itself met with instantaneous success, and Taine became famous. In 1858 appeared a volume of *Essais de Critique et d'Histoire;* in 1860 *La Fontaine et ses Fables,* and a second edition of the *Philosophes Français.*

In 1864 Taine succeeded Viollet-le-Duc as professor of the history of art and aesthetics at the École des Beaux Arts. Renan's

appointment at the Collège de France and Taine's candidature for the Polytechnic School had alarmed Mgr. Dupanloup, who in 1863 issued an *Avertissement à la Jeunesse et aux Pères de Famille,* which consisted of a violent attack upon Taine, Renan and Littré: Renan was suspended, and Taine's appointment to Saint Cyr would have been cancelled but for the intervention of the Princess Mathilde. In December 1863 his *Histoire de la Littérature Anglaise* was published, prefaced by an introduction in which Taine's determinist views were developed in the most uncompromising fashion. In 1864 Taine sent this work to the Academy to compete for the Prix Bordin. M. de Falloux and Mgr. Dupanloup attacked Taine with violence; he was warmly defended by Guizot: finally, after three days of discussion, it was decided that as the prize could not be awarded to Taine, it should not be awarded at all. After three attempts to secure admission to the Academy Taine was elected in November 1878.

The period from 1864 to 1870 was perhaps the happiest of Taine's life. He derived pleasure from his employment at the Beaux Arts and Saint Cyr, which left ample leisure for travel and research. In 1865 appeared *La Philosophie de l'Art,* in 1867 *L'Idéal dans l'Art,* followed by essays on the philosophy of art in the Netherlands (1868), in Greece (1869), all of which short works were republished later (in 1880) as a work on the philosophy of art. In 1865 he published his *Nouveaux Essais de Critique et d'Histoire;* from 1863 to 1865 appeared in *La Vie Parisienne* the notes he had taken for the past two years on Paris and on French society under the sub-title of "Vie et Opinions de Thomas Frédéric Graindorge," published in a volume in 1867, the most personal of his books, and an epitome of his ideas. In 1867 appeared a supplementary volume to his history of English literature, and in January 1870 his *Théorie de l'Intelligence.* In 1868 he married Mademoiselle Denuelle, the daughter of a distinguished architect. He had made a long stay in England in 1858, and had brought back copious notes, which, after a second journey in 1871, he published in 1872 under the title of *Notes sur l'Angleterre.*

Taine, deeply shaken by the events of 1870, now felt that it was the duty of every Frenchman to work solely in the interests of France. On Oct. 9, 1870 he published an article on "L'Opinion en Allemagne et les Conditions de la Paix," and in 1871 a pamphlet on *Le Suffrage Universel;* and his intention of writing on the French Revolution returned in a new and definite shape. He determined to trace in the Revolution of 1789 the reason of the political instability from which modern France was suffering. From the autumn of 1871 to the end of his life his great work, *Les Origines de la France Contemporaine,* occupied all his time, and in 1884 he gave up his professorship in order to devote himself wholly to his task; but he succumbed before it was finished, dying in Paris on March 9, 1893.

Les Origines de la France Contemporaine, Taine's monumental achievement, stands apart from the rest of his work. The problem which Taine set himself was to inquire why the centralization of modern France is so great that all individual initiative is practically non-existent, and why the central power, whether it be in the hands of a man or of an assembly, is the sole and only power; also to expose the error underlying two prevalent ideas:—(1) That the Revolution destroyed absolutism and set up liberty; the Revolution, he points out, merely caused absolutism to change hands. (2) That the Revolution destroyed liberty instead of establishing it; that France was less centralized before 1789 than after 1800. This also he shows to be untrue. France was already a centralized country before 1789, and grew rapidly more and more so from the time of Louis XIV. onwards. The Revolution merely gave it a new form. The *Origines* differ from the rest of Taine's work in that, although he applies to a period of history the method which he had already applied to literature and to the arts, he is unable to approach his subject in the same spirit; he loses his philosophic calm; he cannot help writing as a man and a Frenchman, and he lets his feelings have play; but what the work loses thus in impartiality it gains in life.

Taine was the philosopher of the epoch which succeeded the era of romanticism (1820–50) in France. The ideal of the newer generation was truth; their watchword liberty; to get as near as possible to scientific truth became their object. Taine must ever be regarded as one of the most authoritative spokesmen of this period.

Taine served science unfalteringly, without looking forward to any possible fruits or result. In his work we find neither enthusiasm nor bitterness, neither hope nor yet despair; merely a hopeless resignation. The study of mankind was Taine's incessant preoccupation, and he followed the method already described. He made a searching investigation into humanity and his verdict was one of unqualified condemnation. In "Thomas Graindorge" we see him aghast at the spectacle of man's brutality and woman's folly. In man he sees the primeval savage, the gorilla, the carnivorous and lascivious animal, or else the maniac with diseased body and disordered mind, to whom health, either of mind or body, is but an accident. Taine is appalled by the *bête humaine;* and in all his works we are conscious, as in the case of Voltaire, of the terror with which the possibilities of human folly inspire him. It may be doubted whether Taine's system, to which he attached so much importance, is really the most lasting part of his work. For Taine was an artist as well as a logician, an artist who saw and depicted what he saw in vital and glowing language. From the artist we get his essay on La Fontaine, his articles on Balzac and Racine, and the passages on Voltaire and Rousseau in the *Ancien Régime.* Moreover, not only was Taine an artist who had not escaped from the influence of the romantic tradition, but he was by his very method and style a romanticist. His emotions were deep if not violent, his vision at times almost lurid. He sees everything in startling relief and sometimes in exaggerated outline, as did Balzac and Victor Hugo. Hence his predilection for exuberance, strength and splendour; his love of Shakespeare, Titian and Rubens; his delight in bold, highly-coloured themes.

Taine's influence was great, and twofold. On his own generation it was considerable; during the epoch in which he lived, while a wave of pessimism was sweeping over French literature, he was the high priest of the cult of misanthropy, in which even science was held to be but an idol, worthy of respect and devotional service, but not of faith. In its turn came the reaction against positivism and pessimism, and an attempt at spiritual renascence. Around a man so remarkable as Taine a school is certain to form itself; Taine's school, which was one of positivist doctrines, rigid systems and resigned hopelessness, was equally certain to produce at some time or another a school of determined opponents to its doctrines and system. If, therefore, the tone which pervades the works of Zola, Bourget and Maupassant can be immediately attributed to the influence we call Taine's, it is also the influence of Taine which is one of the ultimate causes of the protest embodied in the subsequent reaction. (M. Bg.; X.)

Bibliography.—The official life, *H. Taine, sa vie et sa correspondance,* was published in 3 vols. in 1902–05 (Eng. trans. by Mrs. R. L. Devonshire, 1902–08). His friend, M. E. Boutmy, published an appreciative study of Taine's philosophy in his *Taine, Scherer, Laboulaye* (Paris, 1901). *See* also A. Sorel, *Nouveaux essais d'histoire et de critique* (1898); Gabriel Monod, *Les Maîtres de l'histoire* (Paris, 1894); Émile Faguet, *Politiques moralistes au XIXe siècle* (Paris, 1900); P. Lacombe, *La psychologie des individus et des sociétés chez Taine* (1906); P. Nève, *La philosophie de Taine* (1908); Victor Giraud, *Essai sur Taine, son oeuvre et son influence, d'après des documents inédits* (2nd ed., 1902); *Bibliographie de Taine* (Paris, 1902). A comprehensive list of books and articles on Taine is given in H. P. Thieme, *Guide bibliographique de la littérature française de 1800 à 1906* (Paris, 1907). For criticisms of Taine's historical work, *see* A. Aulard, *Taine, historien de la Révolution française* (1907); P. Lacombe, *Taine, historien et sociologue* (1909). *See* also A. Laborde-Mataa, *H. Taine* (1909); O. Engel, *Der Einfluss Hegels auf die Bildung der Gedankenwelt H. Taines* (Stuttgart, 1920); M. Barrès, *Taine et Renan* (1922); F. C. Roe, *Taine et l'Angleterre* (1923).

TAIT, ARCHIBALD CAMPBELL (1811–1882), English divine, archbishop of Canterbury, was born at Edinburgh on Dec. 21, 1811, of Presbyterian parents. He entered Balliol college in 1830 as a Snell exhibitioner from the University of Glasgow. He became fellow and tutor of Balliol and was also ordained deacon (1836) and priest (1838), and served the curacy of Baldon. He never sympathized with the principles of the Tractarian

movement, and on the appearance of Tract 90 in 1841 he drafted the famous protest of the "Four Tutors" against it; but this was his only important contribution to the dispute. In 1842 he succeeded Arnold as headmaster of Rugby; and, after a serious illness in 1848, accepted a less strenuous appointment as dean of Carlisle in 1849. During his residence at Carlisle he served on the University Commission, restored his cathedral and did much excellent pastoral work. There too he suffered the great sorrow of his life. He had married Catharine Spooner at Rugby in 1843; in the spring of 1856, within five weeks, five of their children died of scarlet fever. He was consecrated bishop of London on Nov. 22, 1856. He became archbishop of Canterbury in 1868. His last years were interrupted by illness and saddened by the death in 1878 of his only son Craufurd, and of his wife.

Tait was constant in his attendance in parliament, and pressed on many measures of practical utility. The modification of the terms of clerical subscription (1865), the new lectionary (1871), the Burials Act (1880) were largely owing to him; for all of them, and especially the last, he incurred much obloquy at the time. The Royal Commissions on Ritual (1867) and on the Ecclesiastical Courts (1881) were due to him, and he took a large part in the deliberations of both.

Tait was less successful in dealing with matters which called for the higher gifts of a ruler, and especially in his relations with (*a*) the liberal trend in modern thought, and (*b*) the Catholic revival (*i.*) His object in dealing with questions of faith, as in dealing with the ritual question, was primarily a practical one: he wished to secure peace, and obedience to the law as he saw it. Consequently, after his sympathies had led him to express himself favourably towards some movement, he frequently found himself compelled to draw back. He expressed a qualified sympathy with some of the writers of *Essays and Reviews,* and then joined in the censure of it by the bishops (1861) The same kind of apparent vacillation was found in his action in other cases, *e.g*, in the Colenso case (1863), and in the controversy as to the use or disuse of the Athanasian symbol (1872). (*ii*) Tait was concerned with the Catholic revival during the whole of his episcopate, and above all on the side of ritual. He had to deal with the St George's-in-the-East riots in 1859, and the troubles at St. Alban's, Holborn, in their earlier stages (1867); he took part as assessor in the Privy Council judgment in the Ridsdale case (1877); he was more closely concerned than any other bishop with the agitation against confession in 1858, and again in 1877 His method throughout was the same: he endeavoured to obtain a compliance to the law as declared by the courts; failing this, he made the most earnest efforts to secure obedience to the ruling of the Ordinary for the sake of the peace of the Church; after this, he could do nothing. In fact Tait could hardly realize anything but the connection between the English Church and the State. From such a position there seemed to be no escape but in legislation for the deprivation of the recalcitrant clergy; and the Public Worship Regulation Act (1874) was the result. A widespread feeling of indignation spread not only among High Churchmen, but among many who cared little for the ritual practices involved. At length, when A. H. Mackonochie was on the point of being deprived of his benefice of St. Alban's, Holborn, for contumacy, the archbishop, then on his deathbed at Addington, took steps which resulted in the carrying out of an exchange of benefices (which had already been projected), which removed him from the jurisdiction of the court. This proved to be the turning-point; and the ritual difficulty was afterwards dealt with from a different point of view, and the Public Worship Regulation Act became practically obsolete. The archbishop died on Dec. 3, 1882.

See R. T. Davidson and D. Benham, *Life of Archbishop Tait,* 2 vols. (1891); A. C. Tait, *Catharine and Craufurd Tait* (1880).

TAIT, PETER GUTHRIE (1831–1901), Scottish physicist, was born at Dalkeith on April 28, 1831. After attending the Academy at Edinburgh and spending a session at the University, he went up to Peterhouse, Cambridge. As a fellow and lecturer of his college he remained in Cambridge until 1854, and then left to take up the professorship of mathematics at Queen's college, Belfast. There he joined Thomas Andrews (*q v.*) in researches on the density of ozone and the action of the electric discharge on oxygen and other gases. From 1860 to 1901 he was professor of natural philosophy at Edinburgh, where he died on July 4, 1901.

His earliest work dealt mainly with mathematical subjects, and especially with quaternions (*q.v.*), of which he may be regarded as the leading exponent after their originator, Hamilton. With the help of Hamilton and Philip Kelland (1808–1879), he wrote two text books, *Elementary Treatise on Quaternions* (1867), and *Introduction to Quaternions* (1873). He also produced original work in mathematical and experimental physics. In 1864 he published a short paper on thermodynamics, and from that time his contributions to that and kindred departments of science became frequent and important. He worked on thermoelectricity and thermal conductivity, its variation with temperature and its relation to the electrical conductivity of the same material. (*See* HEAT.)

From 1879 to 1888 he was engaged on difficult experimental investigations, which began with an inquiry into the corrections required, owing to the great pressures to which the instruments had been subjected, in the readings of the thermometers employed by the "Challenger" expedition (*q.v*) for observing deep-sea temperatures, and which were extended to include the compressibility of water, glass and mercury. Between 1886 and 1892 he published a series of papers on the foundations of the kinetic theory of gases; and about the same time he carried out investigations into impact and its duration.

A selection only from his papers, published by the Cambridge University Press, fills three large volumes. With Lord Kelvin he collaborated in writing the well-known *Treatise on Natural Philosophy* "Thomson and Tait," as it is familiarly called, but only the first part of it was ever completed.

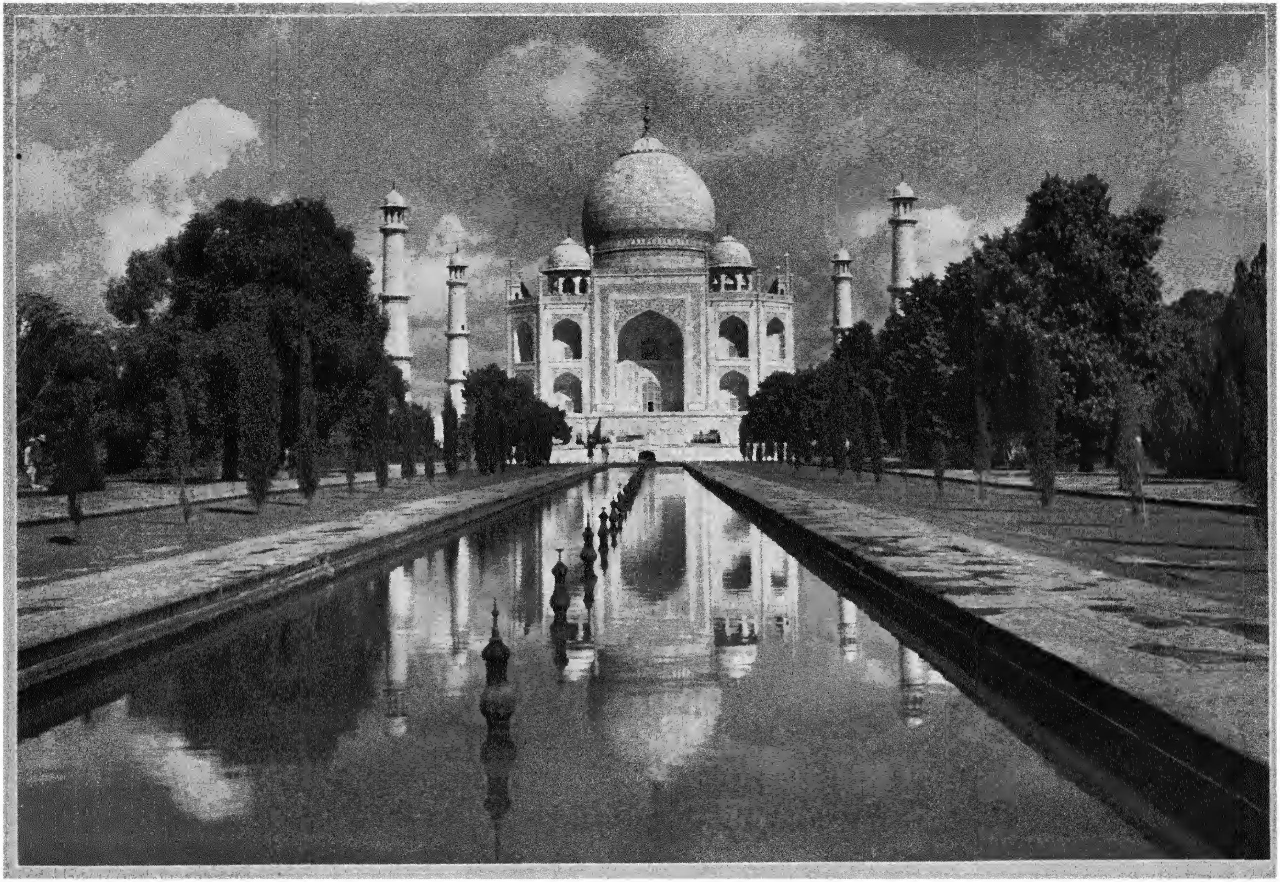
Tait collaborated with Balfour Stewart in the *Unseen Universe* which was followed by *Paradoxical Philosophy*

TAI-YUAN, the chief city of the province of Shansi, China, first noticed about A.D. 450, but greatly developed after the expulsion of the Mongols by the building of a great wall in 1377 Its exposure to attack from Mongolia was the reason for this. It is situated on the Fen-ho river, in a well-peopled plain with many good villages, and is at an altitude of about 2,560ft. above sea-level. The valleys of the plain nearly all have coal mines, and coal is taken by cart to the capital, the population of which was estimated, early in the century, at a quarter of a million, but has been more recently calculated at about 80,000. It formerly made weapons. It has a university and is the terminus of a railway line from the east, which branches from the Peking-Hankow main line. Meteorological observations kept here show a rainfall of 11·6in. per annum, mainly from May to August, more than half the total falling in July, the month of highest average temperature (76·6°) The January average temperature is as low as 18·0°, and in most years a temperature as low as 4·5° is the average minimum for that month.

TAJIK, a subject race of Afghanistan, but the original Persian possessors of the soil, who still speak their mother tongue. The word as now used properly means Arab and was applied to those communities where Arabs settled at the time of the first Arab conquest. They are agriculturalists, organized in village communities, sometimes tenants of Afghan overlords, with headmen in their own villages. They are Sunnites. See *Tribes and Castes of the Punjab and N.W. Frontier Province,* vol. iv. (1914).

TAJIK REPUBLIC, an A.S.S.R. of Russian Central Asia, created in 1924, and lying between the Kirghiz A.S.S.R. on the north, and Afghanistan on the south, and between Uzbekistan on the west and Chinese Turkestan on the east. It consists of the great knot of mountain and plateau belonging to the Pamir-Alai system on the west of the Sarikol range.

Geography and Climate.—The boundary between Russia and Afghanistan, as laid down by the Pamir Boundary Commission in 1895, goes along the Lake Victoria affluent of the Oxus and eastwards along the Nicholas range, dividing the Great and Little Pamirs, so that all the head of the Little Pamir and the Wakhan valley lie in Afghanistan. The Alichur, Rang Kul, Kargosh (Kara Kul) and Sarez Pamirs are in the Tadzhik Republic; a *pamir*



BY COURTESY OF HERBERT G. PONTING, F.R.P.S.

THE TAJ MAHAL, SUPREME ACHIEVEMENT OF MOHAMMEDAN ART

This mausoleum of white alabaster was built (1629–1650) near Agra, India, by Shah Jahan as the burial place for his favourite wife, Mumtaz-i-Mahal. The magnificent exterior is covered with arabesques and passages from the Koran in inlays of precious stones

(Persian *pai-mir* or foot of the mountain peak), is a valley stretching upward in a long slope to the mountain peak, and these high level valleys (Lake Victoria has an altitude of 13,400 ft.) are mainly of glacial formation. The chief ridges crossing the republic are the Turkestan, Zarafshan, Hissar, Trans-Alai, Peter the Great and Darvas. Mt. Kaufmann (23,386 ft.) is the highest peak in the U.S.S.R.

The eastern part of the republic is characterized by broad flat-bottomed valleys, with a series of lakes and low watersheds, and by a severe and dry climate, with an average January temperature as low as that of Novaya Zemlya. The range between day and night temperature is the greatest in the world, and in nine years only 2·3 in. of rain were recorded; this region is bleak and deserted. Of the lakes, Kara-kul (*q.v.*) is the largest, others are Shor-kul, Rang-kul, Yashil-kul, Zor-kul and Sarez. The latter was formed in 1911, from the Murgab (Bartang) river after an earthquake in consequence of which the stream was dammed up by a huge avalanche; Lake Yashik-kul was formed in a similar way.

The Amu-Daria or Oxus is the chief waterway, and under the name of Pandjh, serves as a boundary between Tadzhikstan and Afghanistan; it rises in the Hindu Kush as the Vakhan-darya. Most of the glacier-fed streams in the republic are tributaries of the Amu Daria and flow in a south-westerly direction. Along the right bank of this river and in the lower course of its tributaries, the Kafirnigan and Vaksha, is a desert, with a hot dry summer, which receives less than 10 in. of rainfall per annum.

Fauna and Flora.—The valleys on the west are deeper than those on the east and are divided by high, snowy ridges. The north-western lower slopes are well clad with forest, since they receive more moisture and are less parched in summer. The south-western slopes are less favourable to vegetation, and a south-eastern slope, which means great heat in summer, accompanied by dry winds from Mongolia, is least favourable. Thus in accordance with altitude, slope and type of soil many varieties of vegetation are represented, saxaul scrub, jungle grass, especially in the valleys of the Surkhan, Vaksha and Kyzyl-Su, where the tiger and deer are to be found, deciduous and coniferous forest, and alpine and sub-alpine pasture. Along the north-west runs the upper course of the Zarafshan, with its tributary, the Fan, but the Zarafshan valley here is infertile and difficult to irrigate because of the irregularity of the surface. The most fertile regions are the valleys in which Diushambe and Kurgan-Tyube are situated.

Population and Industry.—The types of dwelling are as varied as the climate and vegetation, *e.g.*, felt tents for the nomads, loess brick walls with a thatch of reeds for the primitive cultivator; the houses are always low, whatever their type, because of the frequent earthquakes. The chief occupation is stock raising of semi-nomadic type, *i.e.*, restricted to certain summer and winter pastures; true nomadism is fast dying out. The disturbances following the 1917 revolution much diminished the herds, the numbers of asses and mules, so essential for transport in this difficult region, are at their former level, cattle, sheep and goats are slowly increasing, but the numbers of camels and horses are still far below 1914 level.

Irrigation cultivation of cotton, rice, olives, vines and fruits in the more favoured valleys in 1926–27 was about 50% less than in 1914, since irrigation works once ruined need much time and capital for their restoration. Wheat and barley are the chief grain crops.

There are valuable minerals, including coal in the Ura-Tyube district and the Zarafshan basin, iron in the latter district and in the valley of the Vanch, where manganese also occurs. These minerals and gold are worked in a primitive way in some localities. Lead, sulphur, asbestos and salt are reported, and there are hot springs, especially at Diushambe. The natural wealth is, however, unsurveyed, and there is little prospect of exploitation in the present absence of means of transport. There are small peasant weaving, carpentry, leather and milling industries to supply local needs only, and of the six industrial enterprises in the republic, four cotton cleaning, one printing and one flour-mill, none was working in 1926–27.

There is no railway; the link with Uzbekistan is a winding road from Derbent to Diushambe, which can be used by motors from April to October only. A railway to link Diushambe via Termez with the trans-Caspian line is planned.

The population consists of Tadzhiks 74·6% and Uzbeks 21·2%, the rest being Kirghiz, Kazaks, Turkmens, Arabs and Jews. It numbered 827,449 in 1926, having been much diminished in the post-1917 disturbances, when many fugitives took refuge in Afghanistan.

The literacy rate is low throughout the republic and in the Badakshan area is probably less than 2%. Education is difficult in this wild country and not more than 12% of the children of school age are provided for; medical help is almost entirely lacking. The Tadzhiks are Mohammedans, but not of a strict type, and in the remoter areas much primitive nature worship survives. Diushambe (*q.v.*) (pop., 1926, 4,485) is the administrative centre.

The Mountain Badakshan Autonomous Area was created within Tadzhikstan in 1925, with Khorog (pop. 1,011) as its centre. It consists of the mountain knot in the south-east, of which 75% is stony and sandy high desert. The climate is severe, average January temperature −20° C, average July +10° C on the east, and −10° C, +22° C on the west. The population in 1926 was 28,374 and consisted of 88% Tadzhiks and 11·4% Kara-Kirghiz. In the east are nomad herdsmen, raising horses, mules, asses, camels, sheep and goats, while in the west scanty crops of rye and wheat supplement herding. Hunting and trapping of marten, fox and otter are additional sources of income and gold is extracted in a primitive way. (R. M. F.)

Nazarov, *Travels in the Pamirs* (1896); Y. D. Golovnin, *To the Pamirs* (1902); A. I. Dmitriev-Mamonov, *Guide through Turkestan* (1903); A. A. Bobrinski, *Mountain Tribes of the Panj* (1908).

TAJ MAHAL, the tomb built at Agra, India, by Shah Jehan for his wife, Mumtaz Mahal, where he is also buried. It was begun in 1632 (in which year the Shah ordered the stopping of all Hindoo temple-building), and was completed before 1650. The Taj Mahal is the most perfect example of the Mogul style and is by some considered the most beautiful building in the world. The tomb proper consists of a domed, square, white marble building, raised on a terrace from the corners of which rise four slim, white minarets. The whole is set in an exquisite garden surrounded by a red sandstone wall; a gate and a mosque are subsidiary elements in the composition. The tomb building itself is 186 ft. square, with a dome 58 ft. in internal diameter rising to a total height of 210 feet. The building is said to have cost over £3,000,000. It was probably designed by an architect named Ustad Isa, traditionally supposed to have been either Turkish or Persian. For a complete description *see* AGRA. *See* also INDIAN ARCHITECTURE.

TAKIN, a hollow-horned ruminant (*Budorcas taxicolor*), which inhabits the south-east corner of Tibet, while a second form is found further east, in the Moupin district. The takin is clumsily built, with yellowish-brown hair and curiously curved horns, which recall those of the gnu. Its nearest relatives appear to be the serows (*q.v.*).

TAKLA MAKAN, a desert area in Central Asia. This unit is the major division of that portion of the Tarim basin which stretches westwards from the lower course of the Tarim river to the Pamirs. Its borders on the west, north and east are formed by the Tiznaf, Yarkand and Tarim rivers respectively.

Speaking generally, the Takla Makan is a region of bare drift sand and moving sand dunes, a waterless area, except for the Khotan and Keriya rivers, which carry water northwards into the desert from the Kunlun. This sand dune desert is absolutely uninhabitable, except for a few scattered settlements along the banks of these rivers. These sandy wastes are found all the way down the right bank of the Tarim river to its confluence with Lake Kara-Buran, and then continue up the Charchan Darya and almost as far westward as Keriya.

The sand dunes proper of the Takla Makan occupy chiefly the south and south-west of the region, where the full force of the north-east wind is felt.

Between the lower Tarim river and the Charchan Darya, the surface conformation is different from that of the rest of the Takla Makan Here the sand dunes are interrupted by tracts of perfectly level soil entirely destitute of sand. In the southernmost part of this area there are patches of reeds and tamarisks, and wells are to be found in this locality.

In the west, stretching from Yangi Hissar to the left bank of the Yarkand river, there is the region of moving sands known as Ordam Padshah In the east, beyond the left bank of the Tarim river, there is a zone of high and barren sand ridges, extending beyond the river and filling the area between the foot of the Kuruk Tagh hills and the belt of wind-eroded desert along the western side of the ancient salt-encrusted Lop lake bed. In this region the sands are much less frequent than in the Takla Makan itself. Here the soil is of loose saline clay, bare in some places, overgrown in others with tamarisk bushes. The plants bind the soil with their roots into a solid mass, the intervals between the masses of plants being subject to the full erosive force of the winds The drift-sand accumulates around the bushes and gradually a hillock of sand and tamarisks is formed. These hillocks are between 7 and 14 ft high, and cover large tracts in this eastward extension of the sandy desert. In the sand dune desert proper of the Takla Makan, there are two systems of dunes; one system, of the high chains, stretches from east to west, while the transverse dunes run from north to south, or north-east to south-west The steeper faces of the dunes are, for the most part, turned towards the south, the south-west and the west, that is, away from the direction of the prevailing winds, but in some regions face east.

Vegetation and animal life are extremely scarce The former is practically confined to various steppe plants, kamish (reeds), tamarisks, almost invariably growing on root mounds, and poplars The animals are hares, rats, and one or two other rodents, foxes, and, in a few places, the wild camel.

The climate is one of extremes. In the Charchan desert a temperature of $-22°$ F has been observed in the depth of winter, and snow sometimes falls heavily there. During the sandstorms which sweep over the region in spring, the thermometer drops as much as 10° or 12° F below zero On the other hand, a temperature as high as 86° F has been recorded at the end of April This desert can only be crossed safely in the winter, when it is possible to transport ice on the backs of camels Sometimes, for days together, the desert is enveloped in an impenetrable dust haze, which chokes and smothers every living creature.

In the second half of the 13th century, Marco Polo left a vivid description of this desert and related legends associated with it (*See* also SIN KIANG, TARIM.)

TAKORADI, a port on the Gold Coast, British West Africa, in 4° 50′ N, 1° 45′ W The main breakwater, 1⅓m. long, is built on a reef which extends 2 to 3m from the rocky foreshore The lee breakwater is ⅔m long: the enclosed area is 270ac and in it ships up to 40ft. draught can lie. Ships 400ft long and 20ft. draught can lie alongside the wharves The port is excellently equipped and can handle 5,000 tons of cargo daily. It is the terminus of the western railway to Kumasi; is the chief port of the Gold Coast, and the only deep water harbour between Sierra Leone and Nigeria, *i e*, on 1,300m of coast. On high ground overlooking the harbour is a model township, built to accommodate 150,000 inhabitants The port was opened to general traffic in 1928

TALAING, a name given to the Mon people of Pegu in Burma, now largely absorbed into and indistinguishable from the Burmese nation The Mon are a remnant of the oldest known civilization of south-east Asia (*see* ASIA, FURTHER), speaking a language which connects with scattered survivals from the Mundas in Chhota Nagpur and the Khasis of Assam to Cambodia, and probably also to Yunnan and the Malay archipelago. The Mon, however, got their culture, their religion, now Buddhist but originally Hindu, and their literature from the Telingana coast of South India, and from the Telingas, whose culture they took and whose foreign blood they absorbed into their own stock, came the name Talaing. This culture was again passed on to the Burmese conquerors of Pegu and Burmese is written in the Talaing alphabet. Burmese law is largely derived from Talaing monastic writings, and Burmese historical tradition is full of Indian nomenclature and Indian legend. (*See* G. E. Harvey, *History of Burma* [1925].) (J. H. H.)

TALANA HILL, ACTION OF, Oct. 20, 1899: *see* SOUTH AFRICAN WAR.

TALAR, the throne of the Persian monarchs which is carved on the rock-cut tomb of Darius at Nakst-i-Rustan, near Persepolis

TALAVERA DE LA REINA, a town of central Spain, in the province of Toledo; on the right bank of the river Tagus, and on the Madrid-Cáceres railway. Pop. (1920), 13,525 Talavera is of great antiquity, the Caesobriga of the Romans Portions of the triple wall which surrounded it remain standing, and the Arco de San Pedro is one of its Roman gates restored. Among the ancient buildings are the Torres Albarranas, built by the Moors in the 10th century, and the Gothic collegiate church The bridge of thirty-five arches across the Tagus dates from the 15th century

Talavera, Battle of, 1809.—For the operations which culminated in the famous battle of Talavera, between the English and the French, and those which followed that engagement, *see* PENINSULAR WAR. Sir Arthur Wellesley (afterwards Duke of Wellington), the British commander, acting in co-operation with Lieutenant-General Cuesta's Spanish army, took position on July 27, 1809, on the Upper Tagus, protected by his advanced guard His line, facing due east, ran north from the right bank of the river to a ridge running parallel to the Tagus, beyond which ridge, also parallel to the river, lay the Sierra de Montalban. Cuesta's men with their right flank resting on the river held Talavera itself and the close country to the northward of it; Wellesley's right connected with Cuesta's left, and his line stretched away northwards to the ridge already mentioned The Sierra was not, on the first day, occupied, and even on the inner ridge itself the division of General Hill was, from a misunderstanding, very late in taking up its position The whole front was covered by a rivulet running from the ridge to the Tagus. The battle was begun by the attack of two French divisions on the British advanced guard, which retired into the main position with severe loss and in some disorder Marshal Victor's forces followed them up sharply, and soon came upon Wellesley's line of battle For some time the retention of the ridge (owing to the delay of Hill's Division) was in doubt, but in the end the arrival of Hill's troops secured this all-important point for the Allied left Meanwhile the Spaniards (though there was at first a temporary panic amongst them) and the right divisions of the British repulsed an attack in the plain, and the day closed with the armies facing each other along the rivulet and on the ridge The losses had been heavy on both sides. Early on the 28th the battle was renewed by a furious attack on Hill's troops, whose left was now prolonged to the Sierra by the Allied cavalry and a division borrowed from Cuesta King Joseph Bonaparte and Jourdan his chief of staff, who were present, were averse to fighting on this present ground, wishing to wait for Soult, whom they expected to come in on Wellesley's rear, and it was only after long discussion that the king gave a reluctant assent to Victor's plan of attack That commander's divisions once more tried to oust Hill from the ridge, and once more failed before the steady volleys of the British line and the charge of the cavalry posted in this quarter (though, owing perhaps to defective ground-scouting, this nearly ended in disaster) At the same time Sebastiani's IV. corps, after a heavy bombardment, assaulted the Allied centre in the plain. Here the British and Spanish battalions held their own firmly, and a counter attack by Mackenzie's division hurled back the French in disorder. Yet another attack followed these failures, and came very near to achieving a great success This time Lapisse's division of Victor's corps attacked the Allies' left centre, composed of the British Guards The French columns were again checked by the British line, but here the counterstroke, unlike Mackenzie's, was carried too far, and the troops in the ardour of incautious pursuit were very severely handled and pushed back to the position by the French reserves; but Wellesley decided the day by a counter attack with the 48th regiment, made with great intrepidity and

steadiness. The Guards, with splendid discipline, resumed their positions, and eventually the French fell back. Failure all along the line and heavy losses left King Joseph no alternative but to retire towards Madrid. The French lost 7,268 men out of 46,138 present, the British 5,363 out of 20,641; the Spanish losses were officially returned at 1,201 out of some 36,000 present.

TALBOT (Family). This is one of the few families in the English aristocracy which traces alike its descent and its surname from the Norman conquerors of England. The name of Richard Talbot occurs in Domesday Book as the holder of nine hides of land in Bedfordshire under Walter Giffard. There is no evidence that he came over to England with the Conqueror himself; and, as he did not hold of the king *in capite*, it is clear that he was not a leader. Talbot being a personal nickname and not derived from a place, those who bore it were not of necessity connected, and the early pedigree is obscure. But a Geoffrey Talbot took part with the empress Maud against King Stephen; and a Hugh Talbot held the castle of Plessis against Henry I. for Hugh de Gournay, and afterwards became a monk at Beaubec in Normandy. Richard Talbot, with whom the proved pedigree begins, obtained from Henry II. on his accession the lordship of Linton in Herefordshire, and from Richard I. the custody of Ludlow Castle. His descendants for some generations appear to have been wardens of various castles on the borders of Wales, and intermarried with the great families of this region. Under Edward II. a Gilbert Talbot was head of the house, and invaded Scotland in the king's company, but afterwards took part with Thomas of Lancaster against the king. He, however, was pardoned, and obtained from Edward III. a confirmation of the grant of the manor of Linton and other lands, being also summoned to parliament as a baron (1331).

His son Richard, who married a daughter and co-heiress of John Comyn of Badenoch, laid claim to lands in Scotland in her right, and, when restrained from entering that country by land (Edward III. having then made an alliance with King David), he joined in an expedition which invaded it by sea in the interests of Edward Baliol. Three years later he was taken prisoner, and redeemed for 2,000 marks, after which the king made him governor of Berwick. He took part also in Edward's wars against France, as did likewise his son Gilbert, who succeeded him. His wife brought him Goodrich Castle on the Wye, and at this time the family possessed lands in the counties of Oxford, Gloucester, Hereford and Kent. Gilbert's son Richard added to this inheritance by marrying the heiress of Lord Strange of Blackmere, and himself became under Richard II. one of the heirs of the earl of Pembroke, thus adding to his estates, lands in Berkshire, Wilts, Salop and Essex. Another Gilbert Talbot, grandson of the last, claimed to carry the great spurs at the coronation of Henry V., and had a commission to receive the submission of Owen Glendower and his adherents. He also distinguished himself in the invasion of Normandy. He left no male issue, and was succeeded by his brother John.

Hitherto the head of the house had borne the name of Lord Talbot; but this John, after obtaining by marriage the title of Lord Furnival, was for his services created earl of Shrewsbury. (*See* Shrewsbury, John Talbot, 1st earl of.)

John, the second earl of Shrewsbury, was the 1st earl's son by his first wife. He had been knighted at Leicester (1426) along with the infant king Henry VI., had served in the wars of France, and been made chancellor of Ireland during his father's lifetime, when he was only Lord Talbot. Afterwards he was made lord high treasurer of England, and in 1459 was rewarded for his services to the house of Lancaster with a grant of 100 marks a year out of the lordship of Wakefield, forfeited by Richard, duke of York. But next year he and his brother Christopher were slain at the battle of Northampton, fighting in the cause of Henry VI. His son John succeeded him, and then his grandson George, who fought for Henry VII. at Stoke, and whom King Henry VIII. sent as his lieutenant against the rebels in the Pilgrimage of Grace.

Francis, the 5th earl, took part in the invasions of Scotland under Henry VIII. and Edward VI., and was one of the two peers who alone opposed the bill for abolishing the pope's jurisdiction under Elizabeth. His son George, who succeeded, was the earl to whom the custody of Mary Stuart was committed, his task being rendered the more difficult by the intrigues of his second wife, Bess of Hardwick, the builder of Chatsworth, who was thrice married before her union with him. Two sons of this last earl succeeded one another, and the title then devolved on the lineal descendants of Sir Gilbert Talbot of Grafton in Worcestershire, third son of John, the 2nd earl.

Charles, the 12th earl, was raised by William III. to the dignity of a duke, but as he left no son this title died along with him in 1718, and the earldom of Shrewsbury devolved on his cousin Gilbert, a Roman Catholic priest.

From this time the direct line of Sir Gilbert Talbot of Grafton began to fail. A nephew three times succeeded to an uncle, and then the title devolved upon a cousin, who died unmarried in 1856. On the death of this cousin the descent of the title was for a short time in dispute, and the lands were claimed for Lord Edmund Howard (now Talbot), an infant son of the duke of Norfolk, under the will of the last earl; but the courts decided that, under a private act obtained by the duke of Shrewsbury shortly before his death, the title and bulk of the estates must go together, and the true successor to the earldom was found in Earl Talbot, the head of another line of the descendants of Sir Gilbert Talbot of Grafton, sprung from a second marriage of Sir Gilbert's son, Sir John Talbot of Albrighton. The head of this family in the beginning of the 18th century was a divine of some mark, William Talbot, who died bishop of Durham in 1730. His son Charles, who filled the office of lord chancellor, was created Baron Talbot of Hensol in Glamorganshire in 1733; and his son William was advanced to the dignity of Earl Talbot in 1761, to which was added Ingestre, the barony of Dynevor, with special remainder to his daughter, Lady Cecil Rice, in 1780. Then succeeded a nephew, who was created Viscount and Earl Talbot, and assumed by royal licence the surname of Chetwynd before Talbot, from his mother.

All the titles just mentioned have been united in the line of the Earl Talbot who successfully claimed the Shrewsbury title as the 18th earl, the earldom of Shrewsbury (1442) being now the oldest existing that is not merged in a higher title. The family seats (Alton Towers and Ingestre Hall) and the chief estates are in Staffordshire. The old badge of the family was a "talbot" or running hound. (J. Gai.; J. H. R.)

TALBOT, MARY ANNE (1778–1808), the "British Amazon," was born in London on Feb. 2, 1778. She believed herself to be the illegitimate child of the 1st Earl Talbot. Early in her career she eloped, in the disguise of a boy, with a captain. In 1792 she was a drummer in Flanders. In the capture of Valenciennes her lover was killed; and Mary Anne deserted and became cabin boy on a French lugger, which she asserted was captured by the British, who transferred her to the "Brunswick," where she served as a powder monkey, being wounded in Lord Howe's victory of June 1, 1794. For this she later received a small pension. When the wound healed she again went to sea, was captured by the French, and imprisoned for a year and a half. Her sex was not discovered until shortly afterwards she was seized by a pressgang. She finally became a household servant to Robert Kirby, a London publisher, who included an account of her adventures in his *Wonderful Museum* (1804) and in *Life and Surprising Adventures of Mary Anne Talbot* (1809). She died on Feb. 4, 1808.

TALBOT, WILLIAM HENRY FOX (1800–1877), English discoverer in photography, was born at Lacock Abbey, Wilts, on Feb. 11, 1800, and died there on Sept. 17, 1877. He was educated at Harrow and at Trinity college, Cambridge. Before L. J. M. Daguerre exhibited in 1839 pictures taken by the sun, Talbot had obtained similar success, and as soon as Daguerre's discoveries became known he communicated the results of his experiments to the Royal Society. In 1841 he made known his discovery of the calotype or Talbotype process, and after the discovery of the collodion process by Frederick Scott Archer in 1851 he devised a method of instantaneous photography. With Rawlinson

and Hincks he was one of the earliest to decipher the cuneiform inscriptions from Nineveh

His works include *Pencil of Nature* (1844); *Hermes or Classical and Antiquarian Researches* (1838–39); *Illustrations of the Antiquity of the Book of Genesis* (1839); *English Etymologies* (1846).

TALBOT OF HENSOL, CHARLES TALBOT, 1ST BARON (1685–1737), lord chancellor of England, the eldest son of William Talbot, bishop of Durham, a descendant of the 1st earl of Shrewsbury, was educated at Eton and Oriel college, Oxford, and became a fellow of All Souls college in 1704. He was called to the bar in 1711, and in 1717 was appointed solicitor-general to the prince of Wales. Having been elected a member of the House of Commons in 1720, he became solicitor-general in 1726, and in 1733 he was made lord chancellor and raised to the peerage with the title of Baron Talbot of Hensol He died on Feb. 14, 1737. Talbot enjoyed the reputation of a wit; he was a patron of the poet Thomson, and Butler dedicated his *Analogy* to the lord chancellor.

See Lord Campbell, *Lives of the Lord Chancellors and Keepers of the Great Seal* (8 vols. London, 1845–69); Edward Foss, *The Judges of England* (London, 1848–64), Lord Hervey, *Memoirs of the Reign of George II.* (London, 1848); G E. C, *Complete Peerage,* vol vii. (London, 1896).

TALC, a mineral which in its compact forms is known as *steatite,* or *soapstone.* It was probably the *μαγνῆτις λίθος* of Theophrastus, described as a stone of silvery lustre, easily cut. The name word comes indirectly from the Arabic *talq,* and is not connected with Swed. *tälja,* to cut It was confused with mica by the older writers, and even now mica is sometimes known in trade as talc; while the term was formerly applied to foliated gypsum.

Talc is occasionally found in small hexagonal and rhombic plates with perfect basal cleavage, which are supposed to be monoclinic, and often occurs in foliated masses, sometimes with a curved surface, readily separating into thin, very flexible, non-elastic laminae The plates give a six-rayed percussion-figure. Talc has a hardness of only about 1, and a specific gravity of from 2·6 to 2 8 Its extreme softness and its greasy feel are characteristic The lustre on the cleavage face is pearly, or sometimes silvery, and one of the old names of the mineral was *stella terrae,* while German writers sometimes called it *Katzensilber.* The colour is white, grey, yellow or frequently green

Talc is a magnesium silicate, $H_2Mg_3Si_4O_{12}$ It is generally regarded as a hydrous silicate, but the water is expelled only at a very strong heat, and may therefore be regarded as basic. By the action of heat the hardness of the mineral is greatly increased Pseudomorphs are known after actinolite, pyroxene, etc., and the mineral has probably been generally formed by the alteration of ferro-magnesian silicates Talc occurs chiefly in crystalline schists, usually associated with chlorite, serpentine and dolomite Fine examples of apple-green colour are found at Mt Greiner, in the Zillerthal, Tirol. Talc-schist is a foliated rock composed chiefly of talc, generally associated with quartz and felspar; but all soapy schists are not necessarily talcose

The *steatites* of Pliny was a stone resembling fat, but otherwise undescribed Being easily cut, steatite has always been a favourite material with the carver. it was used for Egyptian scarabs and other amulets, which were usually coated with a blue vitreous glaze; it was employed for Assyrian cylinder-seals and for other ancient signets, and ancient steatite carvings are found among the ruins of Rhodesia By the Chinese steatite is largely used for ornamental carvings; but many of their "soapstone" figures are wrought in a compact pyrophyllite (*q.v.*), which is essentially different from talc The name agalmatolite is often applied to the material of these figures, and was suggested by M. H. Klaproth from the Greek ἄγαλμα, an image. Pagodite is an old name for Chinese figure-stone.

Steatite is usually a white, grey, greenish or brown substance, occurring in veins or nodular masses or in lenticular bedded deposits. Pseudomorphs after quartz and dolomite occur near Wunsiedel in Bavaria. In some cases it is a product of the alteration of pyroxenic rocks, and the commercial mineral may be very impure. The ease with which steatite may be worked, coupled with its power of resisting heat, has led to its employment for vessels for household use, whence it is called "potstone"—the *lapis ollaris* of old writers; it is also used, especially in America, for sinks, stoves, firebricks, foot-warmers, tips for gas-burners and electric switchboards, and, when ground, as a filler for paper, for leather-dressing, for covering steam-pipes, as an ingredient in soap, for toilet-powder, for certain paints and as a lubricant. A fine granular variety, known as "French chalk" or "Spanish chalk," is used by tailors for marking cloth; slate pencils are made of steatite and pyrophyllite; and in Burma steatite pencils are used for writing on black paper. In the oxyhydrogen flame, steatite has been fused and drawn out into threads, like quartz-fibres.

Steatite- and talc-schists are widely distributed and have occasionally been used as building stones When first raised the stone is soft, but hardens on exposure. Soapstone from Gudbrandsdal is used in the cathedral of Trondhjem, Norway. Veins of steatite occur in the serpentine of the Lizard district, Cornwall, and the mineral was used under the name of soap rock in the manufacture of the old Worcester porcelain. In North America its distribution is very extensive

A fibrous steatite from New York State, used in the manufacture of paper, is known as agalite Rensselaerite is a wax-like talcose substance, passing into serpentine, from St Lawrence county, N Y, named by E Emmons in 1837 after S Van Rensselaer, of Albany, N Y Beaconite is an asbestiform talc from Michigan, named by L W Hubbard The term pyrallolite was given by Nils G Nordenskiöld to a mineral from Finland, which appears to be talc pseudomorphous after pyroxene Talcoid was K F Naumann's name for a white lamellar mineral from near Pressnitz in Bohemia A blue earthy mineral from Silver City, New Mexico, known locally as "native ultramarine," is a magnesium silicate

See "Talc and Soapstone" in vol ii of *Mineral Resources of the U.S.* (1909), and J. H. Pratt, "Economic Papers," No 3, of *Geol. Surv. of N Carolina* (1900), C H. Smyth, Jr, "The Fibrous Talc Industry of St. Lawrence Co, N Y," in *Mineral Industry,* vol ix. (1900), G. P. Merrill, *Non-metallic Minerals* (1904), and R B. Ladoo, "Talc and Soapstone," *U S Bur. of Mines, Bull No 213* (1923).

TALCA, a province of Chile, bounded on the north by Colchagua, east by Argentina, south by Linares and Maule, and west by the Pacific Area 6,909 sq m, including the province of Curicó which in 1928 was incorporated with it Pop. (1928) 210,000 In the east the Andean slopes cover a considerable part of its territory, and in the west another large area is covered by the coast range. Between these is the central valley of Chile in which the population and industries of the province are chiefly concentrated. The lower mountainous parts are well wooded The intermediate plain, which is rolling and slopes gently to the south, is fertile and devoted to wheat, grapes and stock. The capital of the province is Talca (pop, 1920, 36,079), on the Río Claro, a tributary of the Maule, 156 m. by rail south of Santiago

TALCAHUANO, a seaport of the province of Concepción, Chile, on the bay of Talcahuano, 8 m N.W of the city of Concepción Pop (1920) 22,084 It has the best harbour on the Pacific coast of South America, and is one of the most important ports of southern Chile The Chilean Government has established its chief naval depot here.

TALE, a general term, in the usual acceptance of the word, for fictitious narratives, long or short, ancient or modern (O.Eng *talu,* number, account, story, the word is common to many Teutonic languages; *cf.* Ger. *Zahl,* number, *Erzählung,* narrative, Du *taal,* speech, language). In this article "tale" is used in a stricter sense, as equivalent to the German "Volks-märchen" or the French "conte populaire." Thus understood, popular tales mean the stories handed down by oral tradition from an unknown antiquity So understood, popular tales are a subject in mythology. The Homeric epics, especially that of the *Odyssey,* contain adventures (those, for example, of the Cyclops and the husband who returns in disguise) which are manifestly parts of the general human stock of popular narrative. Other examples are found in the *Rigveda,* and in the myths which were handled

by the Greek dramatists. The *Thousand and One Nights* (*q.v.*) is full of popular tales, and popular tales are the staple of the mediaeval *Gesta Romanorum,* and of the collections of Straparola and other Italian story-tellers. In all these and similar gatherings the story, long circulated from mouth to mouth among the people, is handled with conscious art. In the *Histoires ou contes du temps passé* of Perrault (Elzevir, 1697), we have one of the earliest collections of tales which were taken down as they were told by nurses to children.

The success of Perrault's popular tales brought the genre into literary fashion, and the Comtesse d'Aulnoy invented, or in some cases adapted, "contes," which still retain a great popularity. But the precise and scientific collection of tales from the lips of the people is not much earlier than our century. The chief impulse to the study was given by the brothers Grimm. The first edition of their *Kinder- und Haus-Märchen* was published in 1812. The English reader will find a very considerable bibliography of popular tales, as known to the Grimms, in Mrs. Alfred Hunt's translation, *Grimm's Household Tales, with Notes* (1884). In addition to the *märchen* of Indo-European peoples, the Grimms became acquainted with some Malay stories, some narratives of Bechuanas, Negroes, American Indians and Finnish, Estonian and Magyar stories.

For European tales, the bibliography in the translation of Grimm already referred to may be used, and the Maisonneuve collection, *Les Littératures populaires,* may be recommended. There are abundant materials and discussions in Frazer's *The Golden Bough*. *See* also Novel. (A. L.; X.)

TALENT, the name of an ancient Greek unit of weight, the heaviest in use both for monetary purposes and for commodities (*see* Measures and Weights). (Lat. *talentum*, adaptation of Gr. *τάλαντον*, balance, weight, from root *ταλ-*, to lift, as in *τλῆναι*, to bear, *τάλας*, enduring, *cf.* Lat. *tollere,* to lift, Skt. *tulā,* balance.) The weight itself was originally Babylonian, and derivatives were in use in Palestine, Syria and Egypt. In mediaeval Latin and also in many Romanic languages the word was used figuratively, of will, inclination or desire, derived from the sense of balance, but the general figurative use for natural endowments or gifts, faculty, capacity or ability, is due to the parable of the talents in Matt. xxv.

TALFOURD, SIR THOMAS NOON (1795–1854), English judge and author, the son of a brewer, was born at Reading on May 26, 1795. He was educated at Hendon, and at Reading grammar school. At the age of 18 he was sent to London to study law under Joseph Chitty, the special pleader. Early in 1821 he joined the Oxford circuit, having been called to the bar at the middle Temple in the same year. He became a serjeant-at-law in 1835, and a judge of the common pleas in 1849. He was M.P. for Reading, and carried an International Copyright Bill against stormy opposition in 1842. Dickens dedicated the *Pickwick Papers* to him. On the literary side, he contributed to various magazines, and his legal writings on literary subjects included "On the Principle of Advocacy in the Practice of the Bar" (in the *Law Magazine,* Jan. 1846), and his famous *Speech for the Defendant in the Prosecution, the Queen* v. *Moxon, for the Publication of Shelley's Poetical Works* (1841).

But Talfourd cannot be said to have gained any position among men of letters until the production of his tragedy *Ion,* which was privately printed in 1835, and produced in the following year at Covent Garden theatre. Other less successful plays followed. Talfourd died in court during the performance of his judicial duties, at Stafford, on March 13, 1854.

In addition to the writings above-mentioned, Talfourd was the author of *The Letters of Charles Lamb, with a Sketch of his Life* (1837); *Recollections of a First Visit to the Alps* (1841); *Vacation Rambles and Thoughts,* comprising recollections of three continental tours in the vacations of 1841, 1842 and 1843 (2 vols., 1844); and *Final Memorials of Charles Lamb* (1849–50).

TALGARTH, a small town in Breconshire, South Wales, situated on the Ennig near its junction with the Llynfi (a tributary of the Wye), in the north-west section of the Black mountains. It is served by the G.W.R. Pop. (of Parish) 1921, 1,881. A fortified station (Dinas) occupies a hill 2½ m. S.E. of Talgarth, and commands the pass to Crickhowell and the eastern part of the vale of Usk. The region shows evidences of Norman and English penetration and an early distinction between the lowland (English Talgarth) and the upland (Welsh Talgarth) in which the Welsh laws of property etc., prevailed until the end of the middle ages. The region has associations with early nonconformity and there is a Congregational church at Tredwestan founded in 1662. Howel Harris, one of the founders of Welsh Methodism was born in 1713 at Trevecca, 1 m. S.W., and here in 1752 he established a religious "family." Talgarth has a small agricultural trade.

TALIENWAN, an open bay or roadstead on the east side of the Liaotung peninsula, Manchuria. It was leased to Russia by China in 1898 with the naval fortress of Port Arthur, from which it is distant 40 m., the lease being transferred to Japan in 1905. The Russian town of Dalny (now Dairen) was built upon the west side of the bay, which is known as Port Victoria. Talienwan is in railway connection with Niuchwang and Peking and is also connected with Europe by way of the Siberian railway. It was the rendezvous of the British fleet during the Anglo-China war of 1860, whence the names Port Arthur and Port Victoria.

See Dairen.

TALIESSIN (tăl'ĭ-sĭn), a late 6th century British bard, to whom is attributed the collection of poems known as the *Book of Taliessin. See* Welsh Literature.

TALLADEGA, a city of Alabama, U.S.A., the county seat of Talladega county, 35 m. E. of Birmingham, in the foot-hills of the Blue Ridge, at an altitude of 560 feet. It is served by the Atlanta, Birmingham and Coast, the Louisville and Nashville, and the Southern railways. Pop. 6,546 in 1920 (41% negroes); estimated locally at 8,200 in 1928. It is the seat of the State schools for the deaf and the blind and of Talladega college for negroes (Congregational, 1867). Talladega was once the site of an Indian village, where, on Nov. 9, 1813, General Andrew Jackson won a decisive victory over 1,000 "Red Sticks" (Creek Indians) who opposed the extension of white settlement in Indian territory.

TALLAGE was a tax which in England could be imposed by a feudal lord upon his unfree tenants. The king could tallage the towns and his demesne manors. A lesser lord could tallage his demesne manors. The royal tallage of the boroughs to some extent took the place of Danegeld under Henry II., the latter tax having ceased to be very profitable. Growing prosperity made tallages justifiable. Moreover Henry had a better machinery for the assessment and collection of tallage than any king before him. His judges, financial as well as legal experts, were going round the shires more frequently than any previous royal ministers. They could assess the tallages, and the Exchequer (*q.v.*) could see that they were paid. The tax might be arranged by the judges in one of two ways; they might bargain with the town or manor to provide a definite sum for the king, or they might tallage the individual burgesses. The former practice was more usually followed. In the 13th century the custom of summoning representatives from the boroughs to meet the king and his magnates in parliament grew more frequent and the practice of taking tallages from the towns began to fall out of use, since grants were made to the king in the parliament. Nevertheless he kept his right of tallaging the boroughs. Edward I. took a tallage in 1304, his son in 1312. His grandson tried to take one in 1332, but owing to opposition took a grant from parliament instead. In the 12th century the lord seems to have been able to tallage his men at will; his exactions were bounded only by the custom of the manor, which might either limit his right narrowly or allow him considerable latitude in the matter. Beginning with the Inquest of Sheriffs in 1170 the kings took more and more interest in the relations between lord and man, and in time the right of the lord to tallage his men was closely restricted. He had to obtain a license from the king before he could take a tallage. The right of towns, too, to tax individual burgesses was very narrowly limited. The king would allow a tallage to be taken for a necessary public work, or for the payment of sums due to him, but he kept a careful watch on the taxing powers of the borough magistrates. (D. M. S.)

TALLAHASSEE, the capital city of Florida, U.S.A., and the county seat of Leon county; in the northern part of the

State, on Federal highway 90, midway between Jacksonville and Pensacola, and 20 m. N. of the Gulf of Mexico. It has a municipal airport, and is served by the Georgia, Florida and Alabama and the Seaboard Air Line railways. Pop. 6,415 in 1925 (State census), of whom 2,975 were negroes; estimated locally at over 13,000 in 1928. It has a fine location, being situated on a hill 216 ft. above sea-level, in a region of rolling hills, numerous lakes and streams, giant magnolia trees and majestic oaks which are hung with Spanish moss. The streets are wide and well shaded. The State capitol, the Supreme Court and Library building, the Governor's mansion and other public buildings, are dignified and pleasing. The city is a shipping point for cotton, corn, tobacco, fruit and vegetables; has railroad shops and various manufacturing industries; and is the seat of the Florida State college for women and the State Normal and Industrial school for negroes. It has a commission-manager form of government. Tradition says that the Spaniards, about 1638, fortified a hill near the present site of Tallahassee, during a war with the Apalachee Indians. About 1818 most of the Indians were driven out of this region and a settlement was made by the whites, and in 1824 Tallahassee was chosen by the U.S. Government to be the capital of the Territory of Florida. From 1821 it was the home of Charles Louis Napoleon Achille Murat (1801–47; the eldest son of Joachim Murat), who became an American citizen, married a grand-niece of George Washington, and held various municipal offices in Tallahassee. Florida's Ordinance of Secession was adopted by a state convention meeting in Tallahassee on Jan 10, 1861.

TALLBOY (partly a translation and partly a corruption of the French *hautbois*), a double chest of drawers. Whereas the chest of drawers in its familiar form (sometimes in the 18th century called a "lowboy") contains three long and two short drawers, the tallboy has five, six or seven long drawers, and two short ones. It is a very late 17th century development of the smaller chest. The early examples are of walnut, but by far the largest proportion of the many that have survived are of mahogany, that being the wood most frequently employed in the 18th century for the construction of furniture, especially the more massive pieces. Occasionally the walnut at the beginning of the vogue of the tallboy was inlaid, just as satinwood varieties were inlaid, depending for relief upon carved cornice-mouldings or gadrooning, and upon handsome brass handles and escutcheons.

TALLEMANT, GÉDÉON, SIEUR DES RÉAUX (1619–1692), French author, was born at La Rochelle on Nov. 7, 1619. He belonged to a wealthy middle-class family of Huguenot persuasion; the name des Réaux he derived from a small property which was purchased by him in the year 1650. In the *Historiettes* he gives finished portraits of Voiture, Balzac, Malherbe, Chapelain, Valentin Conrart and many others; Blaise Pascal and Jean de la Fontaine appear in his pages; and he chronicles the scandals of which Ninon de l'Enclos and Angélique Paulet were centres. They are invaluable for the literary history of the time. He died in Paris on Nov. 6, 1692.

Des Réaux was a poet of some merit and contributed to the *Guirlande de Julie*, but it is by his *Historiettes* that he is remembered. The work remained in manuscript until it was edited in 1834–36 by MM. de Châteaugiron, Jules Taschereau and L J. N. de Monmerqué, with a notice on Tallemant by Monmerqué. A third edition (6 vols. 1872) contains a notice by Paulin Paris. Tallemant had begun *Mémoires pour la régence d'Anne d'Autriche*, but the manuscript has not been found. *See* also E. Magne, *La joyeuse jeunesse de Tallemant des Réaux* (1921).

TALLEYRAND-PÉRIGORD, CHARLES MAURICE DE (1754–1838), French diplomatist and statesman, was born at Paris on Feb. 12 or 13, 1754, the son of lieutenant-general Charles Daniel de Talleyrand-Périgord. His parents, descended from ancient and powerful families, were in constant attendance at the court of Louis XV. In his third or fourth year, while under the care of a nurse in Paris, he fell from a chest of drawers and injured his foot for life. This accident darkened his prospects; for though by the death of his elder brother he should have represented the family and entered the army, yet he forfeited the rights of primogeniture, and the profession of arms was thenceforth closed to him. At the age of eight he was sent to the Collège d'Harcourt at Paris, and, at thirteen to St. Sulpice, where he conceived a dislike of the doctrines and discipline thrust upon him. After a visit to his uncle, the archbishop of Reims, he returned to St. Sulpice to finish his preliminary training for the church, but in his spare time he read the works of Montesquieu, Voltaire and other writers who were beginning to undermine the authority of the *ancien régime,* both in church and state. As subdeacon he witnessed the coronation of Louis XVI at Reims, but he did not take priest's orders until four years later. While rejecting the authority of the church in the sphere of dogma and intellect, he observed the proprieties of life, and respected the outward observances of religion.

During his life at Paris he frequented the salon of Madame de Genlis, and there formed his ideas in favour of political and social reform. After taking his licentiate in theology in March 1778, he gave little more attention to theological studies. Nevertheless his ability and his social position gained for him in the year 1780 the position of agent-general of the clergy of France. The growing claims of the state on the exchequer of the clergy made his duties responsible. At the extraordinary assembly of the clergy in 1782 he made proposals, by one of which he sought, though in vain, to redress the most glaring grievances of the underpaid *curés.* Though the excellence of his work as agent-general in the years 1780–86 was fully acknowledged, yet he did not gain a bishopric until the beginning of the year 1789, probably because the king disliked him as a freethinker. He now became bishop of Autun, and was installed on March 13.

The Revolution.—The first important act of the new bishop was to draw up a programme of the reforms which he desired to see carried out by the States General of France. It comprised the following items: the formation of a constitution which would strengthen the monarchy by calling to it the support of the whole nation, the drafting of a scheme of local self-government on democratic lines, the reform of the administration of justice and of the criminal law, and the abolition of the most burdensome of feudal and class privileges. This programme was adopted by the clergy of his diocese as their *cahier,* or book of instructions to their representative at the States General, namely Talleyrand himself.

His influence in the estate of the clergy, however, was cast against the union of the three estates in a single assembly, and he voted in the minority of his order which in the middle of June opposed the merging of the clergy in the National Assembly The folly of the court, and the weakness of Louis XVI at that crisis, probably convinced him that the cause of moderate reform and the framing of a bicameral constitution on the model of that of England were hopeless. Thereafter he inclined more and more to the democratic side, though for the present he concerned himself mainly with financial questions. In the middle of July he was chosen as one of the committee to prepare a draft of a constitution; and in the session of the Assembly which Mirabeau termed the *orgie* of the abolition of privileges (Aug. 4) he intervened in favour of discrimination and justice. On Oct. 10, that is, four days after the insurrection of women and the transference of the king and court to Paris, he proposed to the Assembly the confiscation of the lands of the church to the service of the nation, but on terms rather less rigorous than those in which Mirabeau (*q.v.*) carried the proposal into effect on Nov. 2. He identified himself in general with the Left of the Assembly, and supported the proposed Departmental System which replaced the old Provincial System early in 1790. At the federation festival of July 14, 1790 (the "Feast of Pikes") he officiated at the altar reared in the middle of the Champ de Mars. This was his last public celebration of mass. For a brilliantly satirical but not wholly fair reference to the part then played by Talleyrand, the reader should consult Carlyle's *French Revolution,* vol. ii., bk. i., ch. 12. The course of events harmonized with the anti-clerical views of Talleyrand, and he gradually loosened the ties that bound him to the church. He took little part in, though he probably sympathized with, the debates on the measure known as the Civil Constitution of the Clergy, whereby the state enforced its authority over the church to the detriment of its allegiance to the pope.

When the Assembly sought to impose on its members an oath of obedience to the new decree, Talleyrand and three other bishops complied out of the thirty who had seats in the Assembly. The others, followed by the greater number of the clergy throughout France, refused, and thenceforth looked on Talleyrand as a schismatic. He did not long continue to officiate, as many of the so-called "constitutional" clergy did; for, on Jan. 21, 1791, he resigned the see of Autun, and in the month of March was placed under the ban of the church by the pope.

Just before his resignation he had been elected, with Mirabeau and Sieyès, a member of the department of Paris; and for some eighteen months he supported the cause of order in the turbulent capital. Though he was often on strained terms with Mirabeau, their views generally coincided. Talleyrand's reputation for immorality, however, was as marked as that of Mirabeau. While excelling Mirabeau in suppleness and dexterity, Talleyrand lacked the force of character possessed by the great "tribune of the people"; and his influence was gradually eclipsed by the Girondins and the Jacobins.

Debarred from election to the second National Assembly (known as the Legislative) by the self-denying ordinance passed by the "constituents," Talleyrand, at the close of 1791, sought to enter the sphere of diplomacy for which he was well equipped by his mental qualities and his clerical training. The condition of affairs on the continent seemed to French enthusiasts to presage an attack by the other Powers on France. In reality those Powers were far more occupied with the Polish and Eastern questions than with the affairs of France; and the declaration of Pilnitz, drawn up by the sovereigns of Austria and Prussia, which appeared to threaten France with intervention, was recognized by all well-informed persons to be "a loud-sounding nothing." The French foreign minister, Delessart, believed that he would checkmate all the efforts of the *émigrés* at the continental courts provided that he could confirm Pitt in his intention of keeping England neutral. For that purpose Delessart sent Talleyrand, well known for his Anglophil tendencies, to London, but in the unofficial or semi-official capacity which was rendered necessary by the decree of the Constituent Assembly referred to above. Talleyrand arrived in London on Jan. 24, 1792, and found public opinion so far friendly that he wrote off to Paris, "Believe me, a *rapprochement* with England is no chimera." Pitt received him cordially; and to Grenville the envoy stated his hope that the two free nations would enter into close and friendly relations, each guaranteeing the other in the possession of its existing territories, India and Ireland being included on the side of Britain. The British government returned no definite answer to this proposal, but Talleyrand was convinced that Great Britain would not intervene against France unless the latter attacked the Dutch Netherlands.

He returned to Paris on March 10, to persuade the foreign minister (Dumouriez now held that post) of the need of having a fully accredited ambassador at London. The ex-Marquis Chauvelin was appointed, with Talleyrand as adviser. But the overthrow of the monarchy on Aug. 10 and the September massacres rendered hopeless all attempts at an *entente cordiale* between the two peoples; and the provocative actions of Chauvelin undid all the good accomplished by the tact and moderation of Talleyrand. The latter now sought to escape from France, where events were becoming intolerable; he succeeded in obtaining a passport to leave Paris on Sept. 14, and landed in England on the 23rd, avowedly on private business, but still animated by the hope of averting a rupture between the two governments. In this he failed. The provocative actions of the French Convention, especially their setting aside of the rights of the Dutch over the estuary of the Scheldt, had brought the two nations to the brink of war, when the execution of Louis XVI. (21st of Jan. 1793) made it inevitable. Talleyrand was expelled from British soil and made his way to the United States. There he spent thirty months in a state of growing uneasiness and discontent with his surroundings.

The Directory.—The course of events after the Thermidorian reaction of July 1794 favoured his return to France. Thanks to the efforts of Daunou and others his name was removed from the list of *émigrés,* and he set sail for Europe in November 1795. Landing at Hamburg in the January following, he spent some time there in the company of his friends Madame de Genlis and Reinhard; and when party rancour continued to abate at Paris, he returned thither in September. After a time he was recommended by Madame de Staël to the Director Barras for the post of minister of foreign affairs. He gained the post of foreign minister, entering on his duties in July 1797.

Talleyrand, despite the weakness of his own position (he was as yet little more than the chief clerk of his department), soon came to a good understanding with Bonaparte, and secretly expressed to him his satisfaction at the terms which the latter dictated at Campo Formio (Oct. 17, 1797). The *coup d'état* of Fructidor (September 1797) had perpetuated the Directory and led to the exclusion of the two "moderate" members, Carnot and Barthélémy; but Talleyrand saw that power belonged really to the general who had brought about the *coup d'etat* in favour of the Jacobinical Directors headed by Barras.

With the renewal of war on the continent Talleyrand had little or no connection. His powers as minister were limited, and he regretted the extension of the area of war. Moreover, in the autumn of 1797 his reputation for political morality (never very bright) was overclouded by irregular dealings with the envoys of the United States sent to arrange a peaceful settlement of certain disputes with France. Talleyrand refused to clear himself of the charges made against him as his friends (especially Madame de Staël) urged him to do; and the incident probably told against his chances of admission into the Directory, which were discussed in the summer of 1798. A year later he resigned the portfolio for foreign affairs (July 20, 1799), probably because he foresaw the imminent collapse of the Directory. If so, his premonitions were correct. Their realization was assured by the return to France of the "Conqueror of the East" in October. The general and the diplomatist soon came to an understanding, and Talleyrand tactfully brought about the alliance between Bonaparte and Sieyès (*q.v.*) (then the most influential of the five Directors) which paved the way for the *coup d'état* of Brumaire. (*See* FRENCH REVOLUTION and NAPOLEON I.)

Talleyrand's share in the actual events of the 18th, 19th Brumaire (9th, 10th of November) 1799 was limited to certain dealings with Barras on the former of those days. About midday he took to Barras a letter, penned by Roederer, requesting him to resign his post as Director. By what means Talleyrand brought him to do so, whether by persuasion, threats or bribes, is not known; but on that afternoon Barras left Paris under an escort of soldiers. With the more critical and exciting events of the 19th of Brumaire at St. Cloud Talleyrand had no direct connection; but he had made all his preparations for flight in case the blow failed. His reward for helping on the winning cause was the ministry for foreign affairs, which he held from the close of December 1799 on to the summer of 1807. In the great work of reconstruction of France now begun by the First Consul, Talleyrand played no unimportant part. His great aim was to bring about peace, both international and internal. He had a hand in the pacific overtures which Bonaparte, early in the year 1800, sent to the court of London; and, whatever may have been the motives of the First Consul in sending them, it is certain that Talleyrand regretted their failure. After the battle of Marengo an Austrian envoy had to come to Paris in response to a proposal of Bonaparte, and Talleyrand persuaded him to sign terms of peace. These were indignantly repudiated at Vienna, but peace was made between the two Powers at Lunéville on Feb. 9, 1801.

As regards French affairs, Talleyrand used his influence to help on the repeal of the vexatious laws against *émigrés*, nonjuring priests, and the royalists of the west. He was also in full sympathy with the policy which led up to the signature of the Concordat of 1801–2 with the pope (*see* CONCORDAT); but it is probable that he had a hand in the questionable intrigues which accompanied the closing parts of that complex and difficult negotiation. At the end of June 1802 the pope removed Talleyrand from the ban of excommunication and allowed him to revert to

the secular state. On Sept. 10, 1803, owing to pressure put on him by Bonaparte, he married Madame Grand, a *divorcée* with whom he had long been living.

During the meeting of Italian notables at Lyons early in 1802 Talleyrand was serviceable in manipulating affairs in the way desired by Bonaparte, and it is known that the foreign minister suggested to them the desirability of appointing Bonaparte president of the Cisalpine Republic, which was thenceforth to be called the Italian Republic In the negotiations for peace with England which went on at Amiens during the winter of 1801–2 Talleyrand had no direct share, these (like those at Lunéville) being transacted by Napoleon's eldest brother, Joseph Bonaparte (*q.v.*). On the other hand he helped the First Consul in assuring French supremacy in Switzerland, Italy and Germany. In Germany the indemnification of the princes who lost all their lands west of the Rhine was found by secularizing and absorbing the ecclesiastical states of the empire. This unscrupulous proceeding, known as the Secularizations (February 1803), was carried out largely on lines laid down by Bonaparte and Talleyrand; and the latter is known to have made large sums of money by trafficking with the claimants of church lands.

While helping to establish French supremacy in neighbouring states and assisting Bonaparte in securing the title of First Consul for life, Talleyrand sought all means of securing the permanent welfare of France. He worked hard to prevent the rupture of the peace of Amiens in May 1803, and he did what he could to prevent the sale of Louisiana to the United States earlier in the year. These events, as he saw, told against the best interests of France and endangered the gains which she had secured by war and diplomacy. Thereafter he strove to moderate Napoleon's ambition and to preserve the European system as far as possible. The charges of duplicity or treachery made against the foreign minister by Napoleon's apologists are in nearly all cases unfounded. This is especially so in the case of the execution of the duc d'Enghien (March 1804), which Talleyrand disapproved. The evidence against him rests on a document which is now known to have been forged. On the assumption of the imperial title by Napoleon in May 1804, Talleyrand became grand chamberlain of the empire, and received close on 500,000 francs a year.

The Empire.—Talleyrand had rarely succeeded in bending the will of the First Consul. He altogether failed to do so with the Emperor Napoleon. His efforts to induce his master to accord lenient terms to Austria in November 1805 were futile; and he looked on helplessly while that Power was crushed, the Holy Roman Empire swept away, and the Confederation of the Rhine set up in central Europe. In the bargainings which accompanied this last event Talleyrand is believed to have reaped a rich harvest from the German princes most nearly concerned. On July 6, 1806, Napoleon conferred on his minister the title of prince of Benevento, a papal fief in the Neapolitan territory.

In the negotiations with England which went on in the summer of 1806 Talleyrand had not a free hand; they came to nought, as did those with Russia which had led up to the signature of a Franco-Russian treaty at Paris by d'Oubril which was at once disavowed by the tsar. The war with Prussia and Russia was ended by the treaties of Tilsit (7th and 9th of July 1807). Talleyrand had a hand only in the later developments of these negotiations; and it has been shown that he cannot have been the means of revealing to the British government the secret arrangements made at Tilsit between France and Russia, though his private enemies, among them Fouché, have charged him with acting as traitor in this affair.

Talleyrand had long been weary of serving a master whose policy he more and more disapproved, and after the return from Tilsit to Paris he resigned office. Nevertheless Napoleon retained him in the council and took him with him to the interview with the Emperor Alexander I. at Erfurt (September 1808). Talleyrand disapproved of the Spanish policy of Napoleon which culminated at Bayonne in May 1808; and the stories to the contrary may in all probability be dismissed as idle rumours. On Talleyrand now fell the disagreeable task of entertaining at his new mansion at Valençay, in Touraine, the Spanish princes virtually kidnapped at Bayonne by the emperor. They remained there until March 1814. At the close of 1808, while Napoleon was in Spain, Talleyrand entered into certain relations with his former rival Fouché (*q.v.*), which aroused the solicitude of the emperor and hastened his return to Paris. He subjected Talleyrand to violent reproaches, which the ex-minister bore with his usual ironical calm.

After the Danubian campaign of 1809 and the divorce of Josephine, Talleyrand used the influence which he still possessed in the imperial council on behalf of the choice of an Austrian consort for his master, for, like Metternich (who is said first to have mooted the proposal), he saw that this would safeguard the interests of the Habsburgs, whose influence he felt to be essential to the welfare of Europe. He continued quietly to observe the course of events during the disastrous years 1812–13; and even at the beginning of the Moscow campaign he summed up the situation in the words, "It is the beginning of the end" Early in 1814 he saw Napoleon for the last time; the emperor upbraided him with the words: "You are a coward, a traitor, a thief. You do not even believe in God. You have betrayed and deceived everybody. You would sell even your own father." Talleyrand listened unmoved, but afterwards sent in his resignation of his seat on the council. It was not accepted. He had no share in the negotiations of the congress of Châtillon in February–March 1814. On the surrender of Paris to the allies (March 30, 1814), the Emperor Alexander I. took up his abode at the hôtel Talleyrand, and there occurred the conference wherein the statesman persuaded the tsar that the return of the Bourbons was the only possible solution of the French problem, and that the principle of legitimacy alone would guarantee Europe against the aggrandizement of any one state or house. As he phrased it in the Talleyrand *Memoirs:* "The house of Bourbon alone could cause France nobly to conform once more to the happy limits indicated by policy and by nature With the house of Bourbon France ceased to be gigantic in order to be great." These arguments, reinforced by those of the royalist agent de Vitrolles, convinced the tsar; and Talleyrand, on April 1, convened the French senate (only 64 members out of 140 attended), and that body pronounced that Napoleon had forfeited the crown. Ten days later the emperor recognized the inevitable and signed the Act of Abdication at Fontainebleau. The next effort of Talleyrand was to screen France under the principle of legitimacy and to prevent the schemes of partition on which some of the German statesmen were bent. Thanks mainly to the support of the tsar and of England these schemes were foiled; and France emerged from her disasters with frontiers which were practically those of 1792.

The Restoration.—At the congress of Vienna (1814–15) for the settlement of European affairs, Talleyrand, as the representative of the restored house of Bourbon in France, managed adroitly to break up the league of the Powers (framed at Chaumont in February 1814) and assisted in forming a secret alliance between England, Austria and France in order to prevent the complete absorption of Poland by Russia and of Saxony by Prussia The new triple alliance had the effect of lessening the demands of those Powers and of leading to the well-known territorial compromise of 1815. Everything was brought into a state of uncertainty once more by the escape of Napoleon from Elba; but the events of the Hundred Days, in which Talleyrand had no share—he remained at Vienna until June 10—brought in the Bourbons once more; and Talleyrand's plea for a magnanimous treatment of France under Louis XVIII. once more prevailed in all important matters. On July 9, 1815, he became foreign minister and president of the council under Louis XVIII., but diplomatic and other difficulties led him to resign his appointment on Sept. 23, 1815, Louis, however, naming him high chamberlain and according him an annuity of 100,000 francs. The rest of his life calls for little notice except that at the time of the July Revolution of 1830, which unseated the elder branch of the Bourbons, he urged Louis Philippe, duke of Orleans (*q.v*), to take the throne offered to him by popular acclaim. The new sovereign offered him the portfolio for foreign affairs; but Talleyrand signified his preference for the embassy

in London. In that capacity he took an important part in the negotiations respecting the founding of the new kingdom of Belgium. In April, 1834 he crowned his diplomatic career by signing the treaty which brought together as allies France, Great Britain, Spain and Portugal; and in the autumn of that year he resigned his embassy. During his last days he signed a paper signifying his reconciliation with the Roman Catholic Church and his regret for many of his early actions. The king visited his death-bed. His death, on May 17, 1838, called forth widespread expressions of esteem for the statesman who had rendered such great and varied services to his country. He was buried at Valençay. He had been separated from the former Madame Grand in 1815 and left no heir.

The Talleyrand *Mémoires* were edited by the duc de Broglie in 5 vols. (Paris, 1891–92). They have been translated into English by A. Hall, 5 vols. (London, 1891–92). Of his letters and despatches the following are the chief collections:—G. Pallain, *La mission de Talleyrand à Londres en 1792* (Paris, 1889), and *Le ministère de Talleyrand sous le Directoire* (Paris, 1891); P. Bertrand, *Lettres inédites de Talleyrand à Napoléon*, 1800–09 (Paris, 1889); G. Pallain, *Talleyrand et Louis XVIII.* (Paris, 1881), and *Ambassade de Talleyrand à Londres* (1830–34), 2 vols. (Paris, 1891).

Among the biographies, or biographical notices, of Talleyrand the following are, on the whole, hostile to him: G. Touchard Lafosse, *Talleyrand, histoire politique et vie intime* (Paris, 1848); G. Michaud, *Hist. politique et privée de Talleyrand* (Paris, 1853); A. Pichot, *Souvenirs intimes sur Talleyrand* (Paris, 1870); Sainte-Beuve, "Talleyrand," in *Nouveaux lundis*, No. xii.; and Villemarest, *Talleyrand.* The estimate of him of Sir H. L. E. Bulwer Lytton in his *Historical Characters*, 2 vols. (London, 1867) and that of Lord Brougham in *Historical Sketches of Statesmen*, 3 vols. (London, 1845, new edition), are better balanced, but brief. Of recent biographies of Talleyrand the best are Lady Blennerhasset's *Talleyrand* (Berlin, 1894, Eng. translation by F. Clarke, 2 vols. London, 1894); *Talleyrand, a Biographical Study*, by Joseph McCabe (London, 1906); and Bernard de Lacombe, *La vie privée de Talleyrand* (1910); C. Dupuis, *Le Ministère de Talleyrand en 1814* (2 vols., 1919). (J. H. Ro.)

TALLIEN, JEAN LAMBERT (1767–1820), French revolutionary, was born in Paris in 1767. He entered a printer's office, and by 1791 he had reached the position of overseer of the printing department of the *Moniteur*. While thus employed he conceived the idea of the *journal-affiche*, and after the arrest of the king at Varennes in June 1791 he placarded a large printed sheet on all the walls of Paris twice a week, under the title of the *Ami des Citoyens, journal fraternel.*

This enterprise, financed by the Jacobin Club, made him well known to the revolutionary leaders; and he made himself still more conspicuous in organizing the great "Fête de la Liberté" on April 15, 1792, in honour of the released soldiers of Château-Vieux, with Collot d'Herbois. He was active in the events of Aug. 10, and was made clerk to the Revolutionary Commune of Paris. At the close of September he resigned his post on being elected a deputy to the Convention by the department of Seine-et-Oise. He took his seat upon the Mountain, and was one of the most vigorous Jacobins, particularly in his defence of Marat, on Feb. 26, 1793; he was elected a member of the Committee of General Security on Jan. 21, 1793. He took an active part in the *coups d'état* of May 31 and June 2, which resulted in the overthrow of the Girondists. On Sept. 23, 1793, he was sent with Claude Alexandre Ysabeau (1754–1831) to Bordeaux. This was the month in which the Terror was organized under the superintendence of the Committees of Public Safety and General Security.

Tallien showed himself one of the most vigorous of the proconsuls sent over France to establish the Terror in the provinces and soon awed the great city. Among his prisoners was Thérèse, the divorced wife of the comte de Fontenay, and daughter of the Spanish banker, François Cabarrus, one of the most fascinating women of her time, and Tallien not only spared her life but fell in love with her. Suspected of "Moderatism" on account of this incident, Tallien increased, in appearance, his revolutionary zeal, but from the lives Thérèse saved by her entreaties she received the name of "Our Lady of Thermidor," after the 9th of Thermidor. Tallien was even elected president of the Convention on March 24, 1794. Robespierre began to see, however, that he must strike at his own colleagues in the committees if he was to carry out his theories; but they determined to strike first, and on the great day of Thermidor Tallien opened the attack upon Robespierre. Robespierre and his friends were guillotined; and Tallien, as the leading Thermidorian, was elected to the Committee of Public Safety. He suppressed the Revolutionary Tribunal and the Jacobin Club and fought bravely against the insurgents of Prairial. He was supported by Thérèse, whom he married on Dec. 26, 1794, and who became the leader of the social life of Paris. His last political achievement was in July 1795, when he was present with Hoche at the destruction of the army of the *émigrés* at Quiberon, and ordered the executions which followed.

Tallien's political importance came to an end with the Convention for, though he sat in the Council of Five Hundred, the moderates attacked him as terrorist, and the extreme party as a renegade. Madame Tallien also tired of him, and became the mistress of the rich banker Ouvrard. Bonaparte took him to Egypt in his great expedition of June 1798, and he edited the *Décade Egyptienne* in Cairo. But General J. F. Menou sent him away from Egypt, and he was captured by an English cruiser and taken to London, where he had a good reception among the Whigs and was well received by Fox. On returning to France in 1802 he obtained a divorce from his wife (who in 1805 married the comte de Caraman, later prince de Chimay), and was for some time without employment. At last he was appointed consul at Alicante, and remained there until he lost the sight of one eye from yellow fever. On returning to Paris he lived on his half-pay, and his latter days were spent in poverty. He died in Paris on Nov. 16, 1820.

Tallien left an interesting *Discours sur les causes qui ont produit la Révolution française* (1791) and a *Mémoire sur l'administration de l'Égypte à l'arrivée des Français. See* "Tallien et l'Expédition d'Égypte" in *La Révolution Française: Revue d'histoire moderne et contemporaine*, t. iii. p. 269. On Madame Tallien *see* Arsène Houssaye, *Notre Dame de Thermidor* (1866); J. Turquan, *Souveraines et grandes Dames: La citoyenne Tallien, témoignages des contemporains et documents inédits* (1898); and Louis Gastine, *La belle Tallien* (1909).

TALLINN, a seaport of Estonia, the capital of the republic, in 59° 26′ N., 24° 46′ E., on a bay in the south coast of the Gulf of Finland. Pop. (1926) 127,000. Vessels drawing 30 ft. can enter or leave the port and lie alongside the quays. There are floating docks and shipbuilding and repairing yards. The chief exports are textiles, cereals, timber, paper, and Portland cement, and the imports foodstuffs, cotton and coal. There are electric cranes and four ice-breakers. The town has textile, paper, cement, and timber industries; an International Industrial Fair is held annually in June. The grey towers topped with red tiles, the narrow cobbled streets, the remains of the castle and the city walls give the town an attractive appearance and it is developing as a tourist centre. It was formerly called Reval.

A Danish settlement on the high Silurian crag known as the Domberg existed in 1093, and the Danish king Valdemar II. built a castle in 1219, captured by the Livonian Knights in 1228, but returned to the Danes in 1237. Merchants from Lübeck and Bremen settled here in the 13th century and it became a port of the Hanseatic League. It was fortified early in the 14th century, and in 1343 sustained a siege by the revolted Estonians. Valdemar III. sold Reval and Estonia to the Teutonic Knights in 1346, but on the dissolution of the order, in 1561, Estonia and Reval surrendered to the Swedish king Erik XIV. A great conflagration in 1433, the pestilence of 1532, the bombardment by the Danes in 1569, and the Russo-Livonian War, destroyed its trade. The Russians besieged Reval in 1570 and 1577, and in 1710 it was surrendered to Peter the Great, who immediately began the erection of a military port for his Baltic fleet. His successors continued to fortify the access to Reval from the sea, large works being undertaken, especially in the early years of the 19th century. It passed from Russian to Estonian rule in 1918.

TALLIS (TALLYS, TALYS or TALLISIUS), **THOMAS** (*c.* 1515–1585), justly styled "the father of English cathedral music," was born probably before 1515. It has been conjectured that, after singing as a chorister at old Saint Paul's under Thomas Mulliner, he obtained a place among the children of the chapel royal. He is known to have become organist at Waltham abbey,

where, on the dissolution of the monastery in 1540, he received, in compensation for the loss of his preferment, 20s. for wages and 20s. for reward In the library of the British Museum there is preserved a volume of ms. treatises on music, once belonging to the abbey, on the last page of which appears his autograph, "Thomas Tallys"—the only specimen known Not long after his dismissal from Waltham, Tallis was appointed a gentleman of the chapel royal

One of the earliest compositions by Tallis to which an approximate date can be assigned is the well-known *Service in the Dorian Mode,* consisting of the *Venite, Te Deum, Benedictus, Kyrie, Nicene Creed, Sanctus, Gloria in Excelsis, Magnificat* and *Nunc Dimittis,* for four voices, together with the *Preces, Responses, Paternoster* and *Litany,* for five, all published for the first time, in the Rev. John Barnard's *First Book of Selected Church Music,* in 1641, and reprinted, with the exception of the *Venite* and *Paternoster,* in Boyce's *Cathedral Music* in 1760. (Boyce's omission of the very beautiful *Venite* is hard to account for.) That this work was composed for the purpose of supplying a pressing need, after the publication of the second prayer-book of King Edward VI. in 1552, there can be no doubt. Written in the style known among Italian composers as *lo stile famigliare, i.e.,* in simple counterpoint of the first species, *nota contra notam,* with no attempt at learned complications of any kind, it adapts itself with equal dignity and clearness to the expression of the verbal text it is intended to illustrate In self-restraint the *Litany* and *Responses* bear a close analogy to the *Improperia* and other similar works of Palestrina

Tallis raised the English school to a height which it was to maintain until the death of its last representative, Orlando Gibbons, in 1625. Though this school is generally said to have been founded by Dr. Tye, there can be no doubt that Tallis was its greatest master, and that it was indebted to him alone for the infusion of new life and vigour which prevented it from degenerating, as some of the earlier Flemish schools had done, into a mere vehicle for the display of fruitless erudition Like every other great musician of the period, he produced occasionally works confessedly intended for no more exalted purpose than the exhibition of his stupendous skill In his canon *Miserere nostri* (given in Hawkins's *History of Music*) the intricacy of the contrapuntal devices seems little short of miraculous, yet the resulting harmony is smooth and normal, and only the irregular complexity of the rhythm betrays the artificiality of its structure The famous forty-part motet, *Spem in alium,* written for eight five-part choirs, stands on a far higher plane, and the *tour de force* of handling freely and smoothly so many independent parts is the least remarkable of its qualities It was edited by Dr A. H Mann in 1888 (London, Weekes and Company) (In the sixth volume of *Tudor Church Music* [Oxford University Press, 1928] all the forty parts are printed on one page) The art with which the climaxes are built up shows that Tallis's object in writing for forty voices is indeed to produce an effect that could not be produced by thirty-nine But this illustrates one phase only of Tallis's many-sided genius, which shines with equal brightness in the eight psalm tunes (one in each of the first eight modes) and unpretending little *Veni Creator,* printed in 1567 at the end of Archbishop Parker's *First Quinquagene of Metrical Psalms*

In 1575 Tallis and his pupil William Byrd—as great a contrapuntist as himself—obtained from Queen Elizabeth royal letters patent granting them the exclusive right of printing music and ruling music-paper for twenty-one years; and, in virtue of this privilege, they issued, in the same year, a joint work, entitled *Cantiones quae ab argumento Sacrae vocantur, quinque et sex partium,* containing sixteen motets by Tallis and eighteen by Byrd, all of the highest degree of excellence Some of these motets, adapted to English words, are now sung as anthems in the Anglican cathedral service. But no such translations appear to have been made during Tallis's lifetime; and there is strong reason for believing that, though both he and Byrd outwardly conformed to the new religion, and composed music expressly for its use, they remained Catholics at heart.

Tallis's contributions to the *Cantiones Sacrae* were the last of his compositions published during his lifetime. He died on November 23, 1585, and was buried in the parish church at Greenwich, where a quaint rhymed epitaph, preserved by Strype, and reprinted by Burney and Hawkins, recorded the fact that he served in the chapel royal during the reigns of Henry VIII., Edward VI., Mary, and Elizabeth. This was destroyed with the old church about 1710; but a copy has since been substituted Portraits, professedly authentic, of Tallis and Byrd, were engraved by Vandergucht in 1730 for Nicolas Haym's projected *History of Music,* but never published. One copy only is known to exist. A list of the printed and manuscript works of Tallis will be found in Grove's *Dictionary.*

TALLOW, the solid oil or fat of ruminant animals, but commercially obtained almost exclusively from oxen and sheep. The various methods by which tallow and other animal fats are separated and purified are dealt with in the article OILS. Ox tallow occurs at ordinary temperatures as a solid hard fat having a yellowish white colour. The fat is insoluble in cold alcohol, but it dissolves in boiling alcohol, in chloroform, ether and the essential oils The hardness of tallow and its melting-point are to some extent affected by the food, age, state of health, etc., of the animal yielding it, the firmest ox tallow being obtained in certain provinces of Russia, where for a great part of the year oxen are fed on hay New tallow melts at from 42·5° to 43° C, old tallow at 43·5°, and the melted fat remains liquid till its temperature falls to 33° or 34° C. Tallow consists of a mixture of two-thirds of the solid fats palmitin and stearin, with one-third of the liquid fat olein.

Mutton tallow differs in several respects from that obtained from oxen It is whiter in colour and harder, and contains only about 30% of olein. Newly rendered it has little taste or smell, but on exposure it quickly becomes rancid Sweet mutton tallow melts at 46° and solidifies at 36° C; when old it does not melt under 49°, and becomes solid on reaching 44° or 45° C. It is sparingly soluble in cold ether and in boiling alcohol (*See* OILS AND FATS)

TALLOW TREE, in botany, the popular name of a small tree, *Sapium sebiferum,* family Euphorbiaceae, a native of China, but cultivated in India and other warm countries. The seeds are thickly coated with a white greasy substance—so-called vegetable tallow—from which candles are made, and which is also used in soap-making and dressing cloth The butter tree or tallow tree of Sierra Leone is *Pentadesma butyracea,* family Guttiferae. The fruit, which is 4 to 5 in. long and about 3 in in diameter, has a thick fleshy rind abounding in a yellow greasy juice, used as butter.

TALLY. The wooden tally used in reckoning comes from two primitive notions; that of notching (scoring) a piece of wood for counting, as Robinson Crusoe did, and that of the broken stick shared between two parties to a bargain: the developed tally combines both. Use of this double tally, once prevalent all over Europe, is still frequent in the less advanced countries and not unknown in most In England, though now nearly obsolete, it was exceedingly common mediaevally and its methods were highly developed; it endured long in certain connections; and its nomenclature survives in many words, to score at cricket (in Pickwick's day "to notch") derives from the single tally, and the verb "to tally" comes obviously from the double one; and other derivatives are many, if not quite so direct.

In England, however, the chief interest of the tally centres in its public use. This is earlier even than the very early "exchequer" organization (*see* EXCHEQUER); by a date not long after 1100 it was a settled system—a system, moreover, carefully differentiated from any private one and used for money only; and the tally continued to be the recognized form of receipt for payments into the Royal Treasury down to 1826. During this long period, though there were modifications of wording, it changed little outwardly save for a continually increasing length; the original 9in. being extended in one extreme example which still survives at the Bank of England to 8ft 6 inches. This, however, is due solely to the increased number of thousands (notches of the thickness of a man's hand) which the tally might be required to

show; and (apart from any difficulty due to the writing) a 13th century clerk could have interpreted it; the revolutionary changes lie, not in the tally's form, but in its employment.

The Assignment System.—At a very early date anticipation of the royal revenue became habitual and in this practice the tally was invaluable; nothing was easier than to "levy" a tally for a sum due for payment later and to "assign" this as payment to a royal creditor. Probably, at certain periods, creditors themselves had little objection to a practice which, in an age of difficult transport and clumsy currency, held many advantages. At the same time it might obviously lead to the lowering of royal credit and to endless confusion in accounts. Assignments were, in effect, payments; but tallies were essentially receipts; and as such, from the 13th century onwards, were all entered on "receipt rolls" and, later, figured in numerous supplementary series of records. Moreover an "assignment" tally frequently went wrong, and the mediaeval administrator could think of no better device than to substitute a fictitious "loan" on the roll, so as to square the account. The roll of "receipts" might thus include actual payments of cash, sums credited long before they were paid or due, and entries which indicate no payment at all, but rather a debt to be cleared later. The difficulties of the modern historian desiring to use these (exceedingly important) records, with none of the contemporary clerk's expert knowledge, needs no emphasis.

The Last Tally, 1826.—By Pepys' time tally-making at Westminster had become a ritual involving numerous officials, much delay and many fees, and from then onwards periodical attempts were made to destroy it. But vested interest successfully withstood reform till the 18th century; and it was not till 1826 that the last tally was levied and a system of "indented cheque receipts" substituted. A few years later (1834) reforming zeal celebrated its triumph by destroying (in the furnaces which heated the House of Lords) the whole accumulation of ancient tallies, with disastrous results; the old Houses of Parliament were burned and, incidentally (till the casual discovery in 1909, in the Chapel of the Pyx, of about 1,300 Exchequer tallies, practically all "stocks" of the 13th century), English historians were left without an essential clue to the understanding of some of the richest record series in the national collections.

TALMA, FRANÇOIS JOSEPH (1763–1826), French actor, was born in Paris on Jan. 15, 1763. His father, a dentist there, and afterwards in London, gave him a good English education, and he returned to Paris, where for a year and a half he practised dentistry. He made his *début* at the Comédie Française as Seide in Voltaire's *Mahomet* (Nov. 21, 1787). Talma was among the earliest advocates of realism in scenery and costume, being aided by his friend the painter David. His first essay in this direction took the form of appearing in the small rôle of Proculus in Voltaire's *Brutus*, with a toga and Roman headdress, much to the surprise of an audience accustomed to 18th century costume on the stage whatever the period represented might be. Talma possessed in perfection the physical gifts of a great tragedian. At first somewhat stilted and monotonous in his manner, he became by perfection of art a model of simplicity. Talma married Julie Carreau, in whose salon were the principal Girondists.

In 1808 the emperor had taken him to Erfurt and made him play the *Mort de César* to a company of crowned heads. Five years later he took him also to Dresden. Talma was also a friend of Joseph Chénier, Danton, and Camille Desmoulins. In Chénier's anti-monarchical *Charles IX.*, produced on Nov. 4, 1789, a prophetic couplet on the destruction of the Bastille made the house burst into a salvo of applause, led by Mirabeau. This play aroused political dissensions in the Comédie Française which led Talma to establish a new theatre known for a time as the Théâtre de la République, on the site of the present Théâtre Français. Here he won his greatest triumphs. He made his last appearance on June 11, 1826, as Charles VI. in Delaville's tragedy, and he died in Paris on Oct. 19, of that year.

Talma was the author of *Mémoires de Lekain, précédés de réflexions sur cet acteur et sur l'art théâtral*, contributed to the *Collection des mémoires sur l'art dramatique*, and published separately (1856) as *Réflexions de Talma sur Lekain et l'art théâtral.* See *Mémoires de F. J. Talma, écrits par lui-même, et recueillis et mis en ordre sur les papiers de sa famille*, by Alex. Dumas (1850); J. B. J. I. P. Regnault-Warin, *Mémoires sur Talma* (1904).

TALMAGE, THOMAS DE WITT (1832–1902), American Presbyterian preacher, was born near Bound Brook, N.J., on Jan. 7, 1832. He was educated at the present New York university and at the Reformed Dutch theological seminary at New Brunswick, New Jersey. In 1856 he became pastor of a Reformed church at Belleville, N.J., thereafter holding pastorates successively at Syracuse, Philadelphia, Brooklyn and Washington, District of Columbia. During the last years of his life he devoted himself to editing, writing and lecturing. He died in Washington on April 12, 1902.

TALMUD, the great Rabbinical thesaurus which was reduced to writing during the second, fourth and sixth centuries of the Christian Era.

Contents.—The Talmūd (Hebrew "teaching, learning") consists of the *Mishnāh* (Heb. "[oral] repetition, teaching"), a systematic collection of religious-legal decisions developing the laws of the Old Testament, and the *Gĕmārā* (Aramaic "completion, decision," or perhaps also "teaching"), supplementary material, legal and otherwise. Mishnah stands in contrast to *Miqrā* "reading, scripture"; its Aram. equivalent is *Mathnīthā*, from *tĕnā*, "to repeat," whence the appellation *Tannā*, "teacher." These and the terms Gemara, Talmud, etc., are more fully explained in H. L. Strack's invaluable *Einleitung in den Talmud* (Leipzig, 1908), pp. 2 *sqq.* The whole was in two great recensions, Palestinian and Babylonian. Other material related to the Mishnāh is preserved in the *Tōsephtā* (Aram. "addition") and the *Midrāshīm*, and since all these, together with the *Targūmīm*, represent the orthodox Rabbinical literature connecting the Old Testament with mediaeval and modern Judaism, the reader should also consult the articles JEWS (parts ii. and iii.), MIDRASH, TARGUM, and for more detailed and critical treatment the references given to the *Jewish Encyclopedia*.

The Mishnah is a more or less careful arrangement of the extant Oral Law (*see* below). It forms the foundation of the Gemara, and is divided into six *Sĕdārīm* or Orders, each containing a number of *Massektōth* ("weavings," *cf.* the etymology of "text") or Tractates. These are subdivided into *Pĕrāqīm* ("sections") or chapters, and these again into paragraphs or sentences (*Mishnayōth*). For a full list of these and of editions and translations, see *Jew. Enc.*

The Origin of the Mishnah.—A careful distinction was drawn between the Written Law, the Mosaic Tōrāh and the rest of the Scriptures (תּוֹרָה שֶׁבִּכְתָב), and the Oral Law, or Tōrāh by Mouth (תּוֹרָה שֶׁבְּעַל פֶּה). The latter has become codified in the Mishnah. The traditional view is well illustrated in the words ascribed to R. Simeon Lakish, 3rd century A.D.: "What is that which is written, 'I will give thee the tables of stone, and the Law and the Commandment, which I have written, that thou mayest teach them (Ex. xxiv. 12)?' 'Tables,' these are the Ten Words (the Decalogue); the 'Law' is the Scripture; 'and the commandment,' that is the Mishnah: 'which I have written,' these are the Prophets and Writings (*i.e.*, The Hagiographa), 'to teach them,' that is the Gemara—thus instructing us that all these were given to Moses from Sinai." Literary and historical criticism places the discussion on another basis when it treats the Mosaic Tōrāh *in its present form* as a post-exilic compilation (about 5th century B.C.) from sources differing in date, origin and history. There is no *a priori* reason why other legal enactments should not have been current when the compilation was first made; the Pentateuchal legislation is incomplete, and covers only a small part of the affairs of life. Laws must be adjusted from time to time to meet changing needs, and new teaching must justify itself by a re-interpretation of the old writings. Just as the stern common law of the Semites was modified by the milder legislation of the Pentateuch, so, in process of time, further developments ensued. Rabbinic law turned the Lex Talionis into monetary compensation. The

Pharisees were the liberalizing party and stood for the Spirit of the Scriptures, to the letter of which the conservative Sadducees clung. (For an illuminating example *see* J. Z. Lauterbach in *Heb. Union College Annual,* iv. Cincinnati, 1927, pp. 173 *seq.*) It is probable that this process was largely an unconscious one; and even if conscious, the analogy of the conventional "legal fiction" and the usual anxiety to avoid the appearance of novelty is enough to show that it is not to be condemned. Contemporary custom or ideals could appear to have ancient precedents, or by means of an exegetical process they could be directly connected with old models. In the Old Testament many laws in the Mosaic legislation are certainly post-Mosaic and the value of not a few narratives lies, not in their historical or biographical information, but in their treatment of law, ritual, custom, belief, etc. Thus, the problem of the origin or antiquity of the unwritten Oral Law, a living and fluid thing, lies outside the scope of criticism; of greater utility is the study of the particular forms the laws have taken in the written sources which from time to time embody the ever-changing legacy of the past.

Growth of the Mishnah and Gemara.—According to the traditional view the canon of the Old Testament closed with the work of Ezra. He was followed by the *Ṣôphĕrîm,* "scribes" (or the men of the great Synagogue), to the Maccabaean age, and these again by the "Pairs" (*zūgôth,* Gr. ζυγόν) the reputed heads of the Sanhedrin, down to the Herodian age (150–30 B C). The last culminate in Hillel (*q.v.*) and Shammai, the founders of two great rival schools, and to this famous pair the work of collecting *hălākôth* ("legal decisions") has been ascribed. The ensuing period of the *Tannā'îm,* "teachers" (about A D 10–220), is that of the growth of the Mishnah. (On the various teachers, especially the Haggadists, *see* W. Bacher, *Agada der Babylon. Amoräer,* pub. Strassburg, 1879; *A d Tannaiten,* pub 1884, new edition begun in 1903; *A. d. Pal Amoraer,* pub. 1892)

Among the best known representatives of the schools are Rabban (a title given to Hillel's descendants) Gamaliel, the Phil-Hellene and teacher of the apostle Paul (Acts xxii. 3) and his son Simeon (Josephus, *Life,* § 38 *seq* , *Wars,* iv 3, 9), and Rabban Joḥanan b. Zakkai, founder of the seat of learning at Jamnia (Jabneh). A little later (about A D. 90–130) are the famous Gamaliel ii , Eliezer b. Hyrqanos (at Lydda), and Ishmael b. Elisha, the last of whom founded the school at Usha and is renowned for his development of the rules of exegesis framed by Hillel. With Rabbi Aqība (*q.v.*) and the synods of Jamnia (about A D. 90 and 118) a definite epoch in Judaism begins. At Jamnia, under the presidency of Gamaliel II. and Eleazar b Azariah, a collection of traditional *halakoth* was formed in the tractate *'Eduyyôth* (larger than and not to be identified with IV., 7). Here, likewise, was discussed the canonicity of the Song of Songs and of Ecclesiastes, and it is probable that here Aqība and his colleagues fixed the official text of the canonical books. Aqība had an important share in the early development of the Mishnah (Strack, pp. 19, 89); and, in the collecting of material, he was followed notably by the school of Ishmael (about A.D. 130–160), which has left its mark upon the early halakic Midrashim. The more interesting names include R Meir, a well-known haggadist, R Simeon b. Yoḥai, R. Jose b Ḥalaphta and R. Jehudah b 'Ilā'i But, as collections of decisions were made by prominent teachers from time to time, confusion was caused by their differences as regards both contents and teaching (*Sotah, 22a*; *Shabb.* 138*b*). Consequently, towards the close of the second century a thoroughly comprehensive effort was made to reduce the *halakoth* to order

Judah, grandson of Gamaliel II., known as the Prince or Patriarch (*nāsī'*), as *Rabbēnū* ("our teacher"), or simply as "Rabbi" *par excellence,* was the editor. He gathered together the material, using Meir's collection as a basis, and although he did not write the Mishnah as it now is, he brought it into essentially its present shape. His methods were not free from arbitrariness; he would attribute to "the wise" the opinion of a single authority which he regarded as correct; he would ignore conflicting opinions or those of scholars which they themselves had afterwards retracted, and he did not scruple to cite his own decisions.

The period of the *'Āmōrā'îm,* "speakers, interpreters" (about A.D. 220–500), witnessed the growth of the Gemara, when the now "canonical" Mishnah formed the basis for further amplification and for the collecting of old and new material which bore upon it. In Palestine learning flourished at Caesarea, Sepphoris, Tiberias and Usha; Babylonia had famous schools at Nehardea (from the 2nd century A.D.), Sura, Pumbeditha and elsewhere. Of their teachers (who were called Rabbi and Rab respectively) several hundreds are known. R. Ḥiyya was redactor of the *Siphrā* on Leviticus; to him and to R. Hoshaiah the compilation of the *Tōsephtā* is also ascribed. Abbā Arīka or Rab, the nephew of the first mentioned, founded the school of Sura (A D. 219). Rab and Shemuel (Samuel) "the astronomer" (died A D. 254) were pupils of "Rabbi" (*i.e* , Judah, above), and were famed for their knowledge of law; so numerous were their points of difference that the Talmud will emphasize certain decisions by the statement that the two were agreed. The Gemara is much indebted to this pair and to Joḥanan b. Nappāḥā (199–279). The latter, founder of the great school of Tiberias, has indeed been venerated, on the authority of Maimonides, as the editor of the Palestinian Talmud; but the presence of later material and of later names, *e.g.,* Mani b. Jona and Jose b Abin (Abun), refute this view. The Babylonian Rabbah b Naḥmani (died *c.* 330) had a dialectical ability which won him the title "uprooter of mountains" His controversies with R Joseph b. Ḥiyya (known for his learning as "Sinai"), and those between their disciples Abaye and Rābā are responsible for many of the minute discussions in the Babylonian Gemara. Meanwhile the persecutions of Constantine and Constantius brought about the decay of the Palestinian schools, and, probably in the 5th century, their recension of the Talmud was essentially complete. In Babylonia, however, learning still flourished, and with Rab Ashi (352–427) the arranging of the present framework of the Gemara may have been taken in hand. Under Rabba Tosĕpha'a (died 470) and Rabina, *i.e.,* Rab Abina (died 499), heads of the academy of Sura, the Babylonian recension became practically complete.

Finally, the *Sabōrā'ē,* "explainers, opiners" (about 500–540), made some additions of their own in the way of explanations and new decisions.

The Palestinian Recension of the Mishnah and Gemara is called "the Talmud of the Land of Israel," or "T of the West"; a popular but misleading name is "the Jerusalem Talmud " It is an extremely uneven compilation. "What was reduced to writing does not give us a work carried out after a preconcerted plan, but rather represents a series of jottings answering to the needs of the various individual writers, and largely intended to strengthen the memory" (Schechter). Political troubles and the unhappy condition of the Jews probably furnish the explanation; hence also the abundance of Palestinian haggadic literature in the Midrashim, whose "words of blessing and consolation" appealed more to their feelings than did the legal writings. The Pal. Talmud did not attain the eminence of the sister recension, and survives in a very incomplete form, although it was perhaps once fuller It now extends only to Orders I–IV., with the omission of IV. 7 and 9, and with the addition of part of VI 7.

The Two Versions.—The Babylonian Talmud (or Tal. Babli) contains the Gemara to 36½ tractates, but the material is relatively very full, and it is about three times as large as the Pal , although the Gemara there extends to 39 tractates. In the latter the Gemara follows each paragraph of the Mishnah; in the former, references are usually made to the leaves (the two pages of which are called *a* and *b*), the enumeration of the *editio princeps* being retained in subsequent editions. The Mishnah is written in a late literary form of Hebrew; but the Gemara is in Aramaic (except the *Baraithas*), that of the Bab. T. being an Eastern Aram, dialect (akin to Mandaitic), that of the Pal. T. being Western Aram. (akin to Biblical Aram. and the Targums). Greek was well understood in cultured Palestine; hence the latter recension uses many Greek terms which it does not explain; whereas in the Bab. T. they are much less common, and are sometimes punningly interpreted. The Pal. Tal. is the more concise, but it is remarkable for the numerous repetitions of the same passages; these are

useful for the criticism of the text, and for the light they throw upon the incompleteness of the work of compilation. The Bab. Tal., on the other hand, is diffuse and freer in its composition, and it is characterized by the exuberance of Halakah, which is usually rather subtle and far-fetched. Both Talmuds offer a good field for research.

Especially interesting are the *Baraithas* which are preserved in the Gemara in *Hebrew*; they are "external" decisions not included in the more authoritative Mishnah, but they differ from and are sometimes older than the Mishnic material, with which they sometimes conflict (so in particular as regards the rejected decisions of the school of Shammai). They usually begin: "our Masters taught," "it is taught," or "he taught," the verb *tĕnā* (*cf. Tannā'īm,* "teachers") being employed (*see* further *Jew. Ency.* ii. 513 *seq.*). Parallel to the Mishnah is the *Tōsephtā*, an independent compilation associated with R. Nehemiah (a contemporary of Meir and Simeon b. Yoḥai), Ḥiyya b. Abba and others; it is arranged according to the Mishnic orders and tractates, but lacks IV. 9 and V. 9–11. The halakoth are fuller and sometimes older than the corresponding decisions in the Mishnah, and the treatment is generally more haggadic. The method of making the discussions part of an interpretation of the Old Testament (halakic Midrash), as exemplified in the *Tōsephtā,* is apparently older than the abstract and independent decisions of the Mishnah—which presuppose an acquaintance with the Pentateuchal basis—and, like the employment of narrative or historical Midrash (*e.g.,* in the Pentateuch, Chronicles and Jubilees), was more suitable for popular exposition than for the academies.

The Responses of the Geonim.—The Palestinian Talmud, although used by the Qaraites in their controversies, fell into neglect, and the Babylonian recension became, what it has since been, the authoritative guide. With the *Gĕōnīm,* the heads of Sura and Pumbeditha (about 589–1038), we enter upon another stage. The "canonical" Mishnah and Gemara were now the objects of study, and the scattered Jews appealed to the central bodies of Judaism in Babylonia for information and guidance. The Geonim in their "Responses" or "Questions and Answers" supplied authoritative interpretations of the Old Testament or of the Talmud, and regulated the application of the teaching of the past to the changed conditions under which their brethren now lived. The legal, religious and other decisions formulated in the pontifical communications of one generation usually became the venerated teaching of the next, and a new class of literature thus sprang into existence. (*See* GAON.)

Meanwhile, as the Babylonian schools decayed, Talmudic learning was assiduously pursued outside its oriental home, and some Babylonian Talmudists apparently reached the West. However, the fortunes of the Talmud in a hostile world now become part of the history of the Jews, and the many interesting vicissitudes cannot be recapitulated here. (*See* JEWS.) To the use of the Pal. Talmud by the Qaraites in their controversies with the Rabbis we owe the preservation of this recension, incomplete though it is. To the intolerance of Christians are no doubt due the rarity of old mss., and the impure state of the text of both Talmuds. At the same time, the polemics had useful results since the literary controversy in the 16th century (when Johann Reuchlin took the part of the Jews) led to the *editio princeps* of the Babylonian Talmud (Vienna, 1520–23). A change shows itself in the second edition (Basel, 1578–81), when the tractate *Abōdāh Zārāh* was omitted, and those passages which offended the Christians were cancelled or modified.

Characteristics.—Owing to the nature of its contents the Talmud stood sorely in need of aids and guides, and a vast amount of labour (of varying value) has been devoted to it by Jewish scholars.

Neither the Mishnah nor the subsequent Gemara aimed at presenting a digested corpus of law. It is really a large collection of opinions and views, a remarkably heterogeneous mixture of contents, for which the history of its growth is no doubt largely responsible. It appalls the reader with its irregularity of treatment, its variations of style, and its abrupt transitions from the spiritual to the crude and trivial, and from superstition to the purest insight. Like the Koran it is often concise to obscurity and cannot be translated literally; it presupposes a knowledge which made commentaries a necessity even, as we have seen, to the Jews themselves. The opening of Order II. 6, for example, would be unintelligible without a knowledge of the law in Levit. xxiii. 42: "A booth (the interior of which is) about 20 cubits high is disallowed. R. Judah allows it. One which is not ten hands high, one which has not three walls, or which has more sun than shade is disallowed. 'An old booth?' (marks of quotation and interrogation must be supplied). The school of Shammai disallows it; but the school of Hillel allows it," etc. In the Gemara, the decisions of the Mishnah are not only discussed, explained or developed, but all kinds of additional matter are suggested by them. Thus, in the Bab. Gem. to III. 5, the reference in the Mishnah to the Zealots (Σικάριοι) is the occasion for a long romantic account of the wars preceding the destruction of the Second Temple. In IV. 3 the incidental prohibition of the cutting up of a roll of Scripture leads to a most valuable discussion of the arrangement of the Canon of the Old Testament, and other details including some account of the character and date of Job. There are numerous haggadic interpolations, some of considerable interest. Prose mingles with poetry, wit with wisdom, the good with the bad, and as one thing goes on to suggest another, it makes the Talmud a somewhat rambling compilation. It is scarcely a law-book or a work of divinity; it is almost an encyclopaedia in its scope, a store-house reproducing the knowledge and the thought, both unconscious and speculative, of the first few centuries of the Christian era.

Estimates.—Ordinary estimates of the Talmud are often influenced by the attitude of Christianity to Judaism and Jewish legalism, and by the preponderating interest which has been taken in the religious-legal side of the Rabbinical writings. The canonization of oral tradition in the Mishnah brought the advantages and the disadvantages of a legal religion, and controversialists have usually seen only one side. The excessive legalism which pervades the Talmud was the scholarship of the age, and the Talmud suffers to a certain extent because accepted opinions and isolated views are commingled. To those who have no patience with the minutiae of legislation, the prolix discussions are as irksome as the arguments appear arbitrary. But the Talmudical discussions were often merely specialized and technical—they were academical and ecclesiastical debates which did not always touch every-day life; sometimes they were for the purpose of reconciling earlier conflicting views, or they even seem to be mere exhibitions of dialectic skill (*cf.*, perhaps, Mk. xii. 18–23). It may be supposed that this predilection for casuistry stimulated that spirit which impelled Jewish scholars of the middle ages to study or translate the learning of the Greeks. Once again it was—from a modern point of view—old-fashioned scholarship; yet one may now recognize that in the development of European science and philosophy it played a necessary part, and one can now realize that again the benefit was for common humanity rather than for the Jews alone. In any case, the Talmud must be judged, like other authoritative religious literature, by its place in history and by its survival.

Results of Criticism.—The Talmud itself is still the authoritative and practical guide of the great mass of the Jews, and is too closely connected with contemporary and earlier Palestinian history to be neglected by Christians. With the progress of modern research the value of this and of the other old Rabbinical writings is being re-estimated, and criticism has forced a modification of many old views. Thus, an early reference to the *title* of a work does not prove that it is that which is now current; this applies, for example, to the tractate *'Ēduyyōth* (see *Jew. Ency.* viii. 611), and to the Midrash *Siphrē*, which frequently differs from that as known to the Talmud (*ib.,* xi. 331). It has been found that a tradition, however tenacious or circumstantial, is not necessarily genuine, and that, too, in spite of the chain of authorities by which its antiquity or genuineness appeared to be confirmed. Implicit reliance can no longer be necessarily placed upon the reputed authorship or editorship of a work; yet, although many of the views of mediaeval Jews in this respect prove to be erroneous

(*e.g.*, on the authorship of the Zōhar; *see* Kabbalah), they may sometimes preserve the recollection of a fact which only needs restatement (*e.g.*, R. Joḥanan as the editor of the Pal. Talmud).

Finally, the Talmud comes at the end of a very lengthy development of Palestinian thought (*see* Palestine: *History*). It is in the direct line of descent from the Old Testament—intervening literature having been lost—the essence of which it makes its own. Forced by the events of history, this legacy of the past was subjected to successive processes and adapted to the needs of successive generations and of widely different historical and social conditions. Legal compendiums and systems of philosophy served their age and gave place to later developments; and the elasticity of interpretation which characterizes it enabled it to outlive Karaites and Kabbalists. It also escaped the classicism of the Renaissance with its insistence upon the test—*either* fact *or* fiction As an oriental work among an oriental people the moral and spiritual influence of the Talmud has rested upon its connection with a history which appealed to the imagination and the feelings, upon its heterogeneity of contents suitable for all moods and minds, and upon the unifying and regulative effects of its legalism. The relationship of Talmudism to the Old Testament has been likened to that of Christian theology to the Gospels; the comparison, whether fitting or not, may at least enable one to understand the varying attitudes of Jewish thinkers to their ancient sources. With closer contact to the un-oriental West and with the inevitable tendencies of modern western scholarship the Talmud has entered upon a new period, one which, though it may be said to date from the time of Moses Mendelssohn (*see* Jews), has reached a more distinctive stage at the present day. In the weakening of that authority which had been ascribed almost unanimously to the Talmud, and invariably to the Old Testament, a new and greater strain has been laid upon Judaism to reinterpret its spirit once more to answer the diverse wants of its adherents. This is part of that larger and pressing psychological problem of adjusting the "authority" ascribed to past writings to that of the collective human experience; it does not confront Judaism alone, and it must suffice to refer to the writings of "Reformed Judaism"; see, *e.g*, C G. Montefiore, *Liberal Judaism* (1903); *Truth in Religion* (1906); I Abrahams, *Judaism* (1907); *Permanent Values* (1924), and the essays of S. Schechter.

Bibliography—E Deutsch's article on the Talmud in the *Quarterly Review*, Oct 1867 (reprinted in his *Literary Remains*), is noteworthy for the great interest it aroused For other introductions, *see* J. Z. Lauterbach, "Mishnah," and W. Bacher, "Talmud" in the *Jew. Ency.*; S. Schechter, "Talmud," in Hastings' *Dict Bib.*, *E.R.E.*; and also S. Funk, *Entstehung des Talmuds* (Leipzig, 1910). More comprehensive are the handbooks of M Mielziner, *Introd. to the Talmud* (Cincinnati, 1894), M. L Rodkinson, *History of the Talmud* (New York, 1903), and especially H. L. Strack, *Einleitung in den Talmud* (Leipzig, 1908, very concise, but replete with bibliographical and other information). The works already cited in this article or in the art. Midrash, cover the most important departments of the Rabbinical literature, and may be supplemented from the critical Jewish journals, *e.g.*, the *Jewish Quarterly Review*, *Revue des Études Juives* (Paris), and especially the *Monatsschrift f. Gesch. u. Wissenschaft des Judentums* (Breslau). (S. A. C.; X)

TAM, JACOB BEN MEÏR (1100–1171), a grandson of Rashi (*q v.*), was the most famous French glossator (*tosafist*) on the text of the Talmud. In 1147 he was attacked and injured by a disorderly band who had attached themselves to the Crusaders. He escaped to the neighbouring Troyes, where about 1160 was held the first of the Jewish Synods, for which the Rhinelands became celebrated At this meeting it was laid down that disputes between Jew and Jew were not to be carried to a Christian court, but were to be settled by fraternal arbitration. New conditions of life had arisen owing to the closer terms on which Jews and Christians lived, and Jacob Tam was foremost in settling the terms which were to govern the relations, from the Jewish side. His practical ordinances (*Takkanoth*), connected with marriage and divorce, trade and proselytism, as well as with synagogue ritual, bear the stamp of enlightened independence within the limits of recognized authoritative tradition and law. Of his legal work the most important was collected in his *Sefer ha-yashar* He was also a poet and grammarian

See Gross, *Gallia Judaica* (index); M. Schloessinger in *Jewish Encyclopedia*, vii. 36–39. (I. A.)

TAMAI, BATTLE OF, March 13, 1884. This is memorable as the occasion on which the charge of the Sudanese tribesmen, followers of Osman Digna, broke the British "square," although eventually repulsed. For an account *see* Egypt and Sudan, Campaigns in, 1882–1899.

TAMAQUA, an anthracite-mining borough of Schuylkill county, Pennsylvania, U.S.A., 15 m. N.E. of Pottsville, on the Tamaqua (Little Schuylkill) river; served by the Central of New Jersey, the Lehigh and New England and the Reading railways. Pop. (1920) 12,363 (91% native white); 1928 local estimate over 15,000. There are many collieries in the borough and its immediate environs, and the various manufacturing industries (including foundries and machine shops, powder mills, shirt factories and knitting mills) had an aggregate output in 1925 valued at $3,796,150. Settlement here dates from 1799. Anthracite was discovered in 1817, and in 1829 a town was laid out, which in 1833 was incorporated as a borough. The name is an Indian word meaning "running water."

TAMARIND, the name popularly applied to the pods of a leguminous tree, which are hard externally, but within filled with an acid juicy pulp containing sugar and various acids, such as citric and tartaric, in combination with potash. The acid pulp is used as a laxative, the pods being largely imported both from the East and the West Indies. The tree is now widely distributed in tropical countries, but it is generally considered that its native country is in eastern tropical Africa, from Abyssinia southward to the Zambezi. The name (meaning in Arabic "Indian date") shows that it entered mediaeval commerce from India, where it is used, not only for its pulp, but for its seeds, which are astringent, its leaves, which furnish a yellow or a red dye, and its timber. The tree (*Tamarindus indica*) attains a height of 70 to 80 ft., and bears elegant pinnate foliage and purplish or orange veined flowers arranged in terminal racemes

TAMARISK. The genus *Tamarix* gives its name to a small group of shrubs or low trees constituting the tamarisk family, Tamaricaceae. The species of tamarisk and of the very closely allied genus *Myricaria* grow in salt-deserts, by the sea-shore, or in other more or less sterile localities in warm temperate, subtropical, and tropical regions of the eastern hemisphere. Their long slender branches bear very numerous small appressed leaves, in which the transpiring surface is reduced to a minimum The flowers are minute and numerous, in long clusters at the ends of the branches or from the trunk Each has 4–5 free sepals, and as many petals springing with the 4–10 stamens from a fleshy disk In *Tamarix* the stamens are free, while in *Myricaria* they are united into one parcel. The fruit is capsular, and contains numerous seeds, each usually with a long tuft of hairs at one end. The great value of these shrubs or trees lies in their ability to withstand the effects of drought and a saline soil, in consequence of which they grow where little else can flourish. On this account the common tamarisk, *T gallica,* is planted on sea-coasts, and affords shelter where none other could be provided. *T. articulata,* native to western Asia, has been introduced as a windbreak in desert areas in southern California. Several species are cultivated as ornamentals. For tamarisk manna, *see* Manna

TAMATAVE (known by the natives as *Tòamàsina*) (pop 15,022), the chief seaport of Madagascar, situated nearly on the centre of the eastern coast in 18° 10′ S., 49° 32′ E. It owes its importance to the existence of a coral reef, which forms a spacious harbour, entered by two openings but unfortunately exposed to frequent cyclonic storms and to a tidal bore. The town is built on a sandy peninsula on which are crowded numerous houses, with good shops and merchants' offices in the main thoroughfares. Tamatave is the seat of several foreign consuls, as well as of numerous French officials, and is the chief port for the capital and the interior. Imports consist principally of piece-goods, farinaceous foods, and iron and steel goods, and exports of gold dust, raffia, hides, caoutchouc and live animals. The town possesses several meat preserving factories. Communication with Europe is maintained by steamers of the Messageries Maritimes and the

Havraise companies, and also with Mauritius, and from thence to Ceylon, by the British Union-Castle line. Of the whole foreign trade of Madagascar, 46 per cent is through Tamatave. The town is connected with the interior of the country by a network of roads and railways. Since 1895 the native population has settled in a new village to the north-west.

TAMAULIPAS, a northern Gulf-coast State of Mexico. Area 30,734 sq. miles. Pop. (1921) 286,904. The central and southern parts of the State are mountainous, but there are extensive fertile plains in the north sloping gently north-east toward the Rio Grande, and the coastal zone is sandy, much broken by lagoons and sparsely inhabited. Except in the north this coastal zone is only 5 to 7 m. wide, but the foothills region back of this is usually well wooded and fertile, and the low alluvial river valleys penetrate deeply into the sierras. There are four important rivers in the State—the Rio Grande del Norte or Rio Bravo, which forms the boundary line with the United States, the Conchas or Presas, the Soto da Marina and the Tamesi. The Pánuco forms the southern boundary for a short distance. A peculiar feature of the hydrography of Tamaulipas is the series of coastal lagoons formed by the formation of new beaches across the indentations of the coast. The climate is hot and humid on the coast, but is pleasant on the more elevated lands of the interior. The rainfall is abundant, especially on the mountain slopes of the south. The principal industry is agriculture. Sugar, cereals, tobacco, cotton and coffee are produced, and probably fruit may be raised successfully. Stock-raising receives some attention and hides and cattle are exported. The preparation of ixtle fibre for export is becoming an important industry. Copper is mined and extensive deposits of petroleum and asphalt are being exploited. Railway communication is provided by the Mexican National, two branches of which cross the northern end of the State, the line from Monterrey to Tampico, and a branch of the Mexican Central from San Luis Potosi to Tampico.

The capital of Tamaulipas is Ciudad Victoria (pop., 1921, 17,124), a small sierra town on the Monterrey and Tampico railway, about 120 m. from Tampico. Among other towns in the State may be mentioned: Matamoros (*q.v.*), Tampico (*q.v.*), Tula (3,192 in 1921), Nuevo Laredo, on the American border (14,998 in 1921), and Doña Cecilia (15,298 in 1921).

TAMAYO Y BAUS, MANUEL (1829–1898), Spanish dramatist, came of a family connected with the theatre, his mother being the eminent actress, Joaquina Baus. The earliest of his printed pieces, *Juana de Arco* (1847), is an arrangement from Schiller, as also is *Angela* (1852), while *Virginia* (1853) is a dramatic essay in Alfieri's manner. *La Locura de Amor* (1855) established Tamayo's reputation as Spain's leading playwright. *Hija y Madre* (1855) is a failure, and *La Bola de Nieve* (1856) is notable solely for its excellent workmanship. Tamayo's straitened means during the next few years forced him to put original work aside and to adapt pieces from Léon Laya, Jules Sandeau and Émile Augier. In this period he produced only one original piece, *Lances de Honor* (1863), which turned upon the immorality of duelling, and led to a warm discussion among the public.

TAMBOV, a province of the Russian S.F.S.R., surrounded by those of Voronezh, Orel, Tula, Ryazan, Penza, Saratov and Stalingrad. Area 46,742 sq.km. Pop. (1926) 2,721,173. It is much smaller than the pre-1917 province of the same name, part of which is now in Ryazan province, and is included in the recently created Black Earth area (Central) (*q.v.*). It consists of an undulating plain (450–800 ft.), intersected by deep ravines and broad valleys, the Don and its tributaries, the Voronezh, Vorona and Khoper, drain it towards the south, and the Tsna links it with the Oka on the north. Cretaceous and Jurassic deposits, thickly covered with boulder clay and loess conceal the underlying Devonian and Carboniferous strata. Phosphorite beds exist in the north-east and are used for the production of chemical manure; iron is mined in the Lipetsk district, which also has mineral springs, and limestone, clay and gypsum are worked. The soil is black earth, very fertile in the Borisoglyebsk district, but having a lower humus content towards the north, where wild cherry and almond abound. For climate, the difficulties of agriculture and general social conditions, *see* VORONEZH, noting however that Tambov has a smaller annual rainfall.

The population is mainly Great Russian in origin, settlement beginning from the principality of Moscow at a very early date, but Tatar raids prevented active colonisation until the end of the 17th century, when landowners who had received large grants of land from the tsars began to bring their serfs from central Russia. There were some Finnish tribes in occupation, and the Mordva still form an independent group in the province. After the disturbances of the 1917–20 civil war, and the retreat of Denikin's army (1920), the province was infested for some time by troops of bandits, and is only slowly recovering from the devastation and famine of that dreadful time.

TAMBOV, chief town of the above province, situated on the Tsna river (non-navigable), and at a railway junction, in 52° 45′ N., 41° 23′ E. Pop. (1926) 72,481. It has smelting works, a railway repair shop, steam flour mills, distilleries and brick works. The absence of a navigable river lessens its trading importance, though it has a grain elevator. The town was founded in 1636 as a fort against Tatar and Kalmuck raids, was a station for part of Peter the Great's army during his attack on Azov, and later was centre of Tambov province, created in 1796.

TAMERLANE: *see* TIMUR.

TAMILS, the Sanskrit generic appellation for the south Indian peoples and their languages, which passed through various stages—Dravida, Dramiḍa, Dramila, Damila. Bishop Caldwell fully explains this in his *Comparative Grammar of the Dravidian Languages* (2nd ed., 1875, p. 10 *seq.*). The term Tamulic or Tamulian has occasionally been employed as the designation of the whole class of Dravidian peoples and languages. The Tamils proper are smaller and of weaker build than Europeans, though graceful in shape. The hair is plentiful, and occasionally curly. The skin varies from brown to black. Of medium stature, they are in general long headed with medium noses. They are enterprising, and wherever money is to be earned there will Tamils be found, either as merchants or in the capacity of domestic servants and labourers. The tea and coffee districts of Ceylon are peopled by about 950,000; Tamils serve as coolies in the Mauritius and the West Indies; in Burma, the Straits, and Siam the so-called Klings are all Tamils. They have settlements in East and South Africa.

Language.—Tamil is still the principal language of the Madras Presidency; in Tanjore and Tinnevelly it is supreme. In Coimbatore it is dominant, is second in Chittoor and the Nilgiris (*Census of India* 1921, vol. xiii.). Tamil is a sister of Malayâḷam, Telugu, Kanarese, Tulu; and, as the oldest, richest, and most highly organized of the Dravidian languages, is typical of that family. The one nearest akin to it is Malayâḷam, originally a dialect of Tamil, but now differing from it in pronunciation and in idiom, in the retention of old Tamil forms obsolete in the modern language, and in having discarded all personal terminations in the verb, the person being always indicated by the pronoun. Also, the proportion of Sanskrit words in Tamil is less than in any other Dravidian tongue.

The modern Tamil characters originated "in a Brahmanical adaptation of the old Grantha letters corresponding to the so-called Vaṭṭeḷuttu," or round-hand, an alphabet once in vogue throughout the whole of the Pâṇḍyan kingdom, as well as in the South Malabar and Coimbatore districts, and still sparsely used for drawing up conveyances and other legal instruments. It is also used by the Moplahs in Tellicherry, while in Malabar it continued in general use down to the end of the 17th century. The modern Tamil characters, which have changed but little for the last 500 years, differ from all the other modern Dravidian alphabets both in shape and in their phonetic value. Their angular form is said to be due to the widespread practice of writing with the style resting on the *end* of the left thumb-nail, while the other alphabets are written with the style resting on the left side of the thumb.

The Tamil alphabet is sufficiently well adapted for the expression of the twelve vowels of the language (*a, â, i, î, u, û, e, ê, o, ô, ei, au*),—the occasional sounds of *ö* and *ü*, both short and

long, being covered by the signs for *e, ê, i, î;* but it is utterly inadequate for the proper expression of the consonants, inasmuch as the one character *k* has to do duty also for *kh, g, gh,* and similarly each of the other surd consonants *ch, ṭ, t, p* represents also the remaining three letters of its respective class The letter *k* has, besides, occasionally the sound of *h,* and *ch* that of *s.* Each of the five consonants *k, ch, ṭ, t, p* has its own nasal. In addition to the four semivowels, the Tamil possesses a cerebral *ṛ* and *ḷ* and has retained a liquid *ḻ,* once peculiar to all the Dravidian languages, the sound of which varies in different districts. There is, lastly, a peculiar *n,* differing in function but not in pronunciation from the dental *n* The three sibilants and *ḥ* of Sanskrit have no place in the Tamil alphabet; but *ch* often does duty as a sibilant in writing foreign words, and the four corresponding letters as well as *j* and *ksh* of the Grantha alphabet are now frequently called to aid. Many of the Sanskrit words imported into Tamil at various periods have therefore assumed disguises under which the original is scarcely recognizable. examples are *ulagu* (loka), *uruvam* (rûpa), *arukkan* (arka), *arputam* (adbhutam), *naṭchattiram* (nakshatram), *iruḍi* (ṛishi), *tîrkam* (dîrgha), *arasen* (râjan).

Tamil has borrowed from Hindustani, Arabic, and Persian a large number of revenue, political, and judicial terms, and more recently a good many English words have crept in, such as *tiraṭṭi,* treaty, *paṭlar,* butler, *âkṭ,* act, *kulôb,* club, *kavarnar,* governor, *pinnalkôdu,* penal code, *sîkku,* sick, *mejastirattu,* magistrate. Of Tamil words which have found a permanent home in English may be mentioned curry (*kaṛi*), mulligatawny (*milagu,* pepper, and *taṇṇîr,* cool water), cheroot (*suruttu*), pariah (*paṛeiyan*)

The Older Literature.—The early existence, in southern India, of peoples, localities, animals and products the names of which, as mentioned in the Old Testament and in Greek and Roman writers, have been identified with corresponding Dravidian terms, goes far to prove the high antiquity, if not of the Tamil language, at least of some form of Dravidian speech (Caldwell, *loc. cit.,* Introd., pp. 81–106; *Madras District Manual,* i., Introd., pp. 134 *seq*). But practically the earliest extant records of the Tamil language do not ascend higher than the middle of the 8th century of the Christian era, the grant in possession of the Israelites at Cochin being assigned by the late Dr. Burnell to about A.D 750, a period when Malayâlam did not exist yet as a separate language. There is every probability that about the same time a number of Tamil works sprung up, which are mentioned by a writer in the 11th century as representing the old literature (Burnell, *loc. cit.,* p. 127, note). The earlier of these may have been Saiva books; the more prominent of the others were decidedly Jain Though traces of a north Indian influence are palpable in all of them that have come down to us (see *e g.,* F. W. Ellis's notes to the *Kuṛal*), we can at the same time perceive, as we must certainly appreciate, the desire of the authors to oppose the influence of Brahmanical writings, and create a literature that should rival Sanskrit books and appeal to the sentiments of the people at large. But the refinement of the poetical language, as adapted to the genius of Tamil, has been carried to greater excess than in Sanskrit; and this artificial character of the so-called Sen-Tamil is evident from a comparison with the old inscriptions, which are a reflex of the language of the people, and clearly show that Tamil has not undergone any essential change (Burnell, *loc. cit.,* p. 142).

The rules of Sen-Tamil appear to have been fixed at a very early date. The *Tolkâppiyam,* the oldest extant Tamil grammar, is assigned by Dr. Burnell (*On the Aindra School of Sanskrit Grammarians,* pp. 8, 55) to the 8th century (best edition by C. Y. Tâmodaram Pillei, Madras, 1885). The *Virasôḻiyam,* another grammar, is of the 11th century. Both have been superseded by the *Nannûl,* of the 15th century, which has exercised the skill of numerous commentators, and continues to be the leading native authority (English editions in Pope's *Third Tamil Grammar,* and an abridgment by Lazarus, 1884). The period of the prevalence of the Jains in the Pâṇḍya kingdom, from the 9th or 10th to the 13th century, is justly termed the Augustan age of Tamil literature. To its earlier days is assigned the *Nâlaḍiyâr,* an ethical poem on the three objects of existence, which is supposed to have preceded the *Kuṛaḷ* of Tiruvaḷḷuvan, the finest poetical production in the whole range of Tamil composition. Tradition, in keeping with the spirit of antagonism to Brahmanical influence, says that its author was a pariah It consists of 1,330 stanzas on virtue, wealth and pleasure. It has often been edited, translated and commented upon; see the introduction to the excellent edition published by the Rev. Dr Pope, in which also a comprehensive account of the peculiarities of Sen-Tamil will be found. To the Avvei, or Matron, a reputed sister of Tiruvaḷḷuvan, but probably of a later date, two shorter moral poems, called *Attisûḍi* and *Konṛeivêyndan,* are ascribed, which are still read in all Tamil schools *Chintâmani,* an epic of upwards of 3,000 stanzas, which celebrates the exploits of a king Jîvakan, also belongs to that early Jain period, and so does the *Divâkaram,* the oldest dictionary of classical Tamil. The former is one of the finest poems in the language; but no more than the first and part of the third of its thirteen books have been edited and translated. Kamban's *Râmâyanam* (about A D 1100) is the only other Tamil epic which comes up to the *Chintâmani* in poetical beauty

The most brilliant of the poetical productions which appeared in the period of the Saiva revival (13th and 14th centuries) are two collections of hymns addressed to Siva, the one called *Tiruvâsakam,* by Mâṇikka-Vâsakan, and a later and larger one called *Tivâram,* by Sambandhan and two other devotees, Sundaran and Appan. Both these collections have been printed, the former in one, the latter in five volumes. They are rivalled both in religious fervour and in poetical merit by a contemporaneous collection of Vaishnava hymns, the *Nâlâyira-prabandham* (also printed at Madras). The third section of it, called *Tiruvâymoli* or "Words of the Sacred Mouth," has been published in Telugu characters, with ample commentaries, in ten quartos (Madras, 1875–76).

After a period of literary torpor, which lasted nearly two centuries, King Vallabha Deva, better known by his assumed name Ativîrarâma Pâṇḍyan (second half of the 16th century), endeavoured to revive the love of poetry by compositions of his own, the most celebrated of which are the *Neidadam,* a somewhat extravagant imitation of Srî Harsha's Sanskrit *Naishadham,* and the *Veṛrivêrkei,* a collection of sententious maxims Though he had numerous followers, who made this revival the most prolific in the whole history of Tamil literature, none of the compositions of any kind, mainly translations and bombastic imitations of Sanskrit models, have attained to any fame. An exceptional place, however, is occupied by certain Tamil sectarians called *Sittar* (i.e , *siddhas* or sages), whose mystical poems, especially those contained in the *Sivavâkyam,* are said to be of singular beauty. Two poems of high merit, composed at the end of the 17th century, also deserve favourable notice—the *Nîtineṛiviḷakkam,* an ethical treatise by Kumâragurupara Desikan, and the *Prabhulingalîlei,* a translation from the Kanarese of a famous text-book of the Vîra-Saiva sect. *See* the analysis in W. Taylor's *Catalogue,* vol. ii. pp. 837–47.

The Modern Period, which may be said to date from the beginning of the last century, is ushered in by two great poets, one native and the other foreign *Tâyumânavan,* a philosopher of the pantheistic school, composed 1,453 stanzas (*pâdal*) which have a high reputation for sublimity both of sentiment and style; and the Italian Jesuit Joseph Beschi (d. 1742), under the name Vîramâmuni, elaborated, on the model of the *Chintâmani,* a religious epic *Têmbâvani,* which, though marred by blemishes of taste, is classed by native critics among the best productions of their literature. It treats of the history of St. Joseph, and has been printed at Pondicherry in three volumes, with a full analysis. English influence has here, as in Bengal and elsewhere in India, greatly tended to create a healthier tone in literature both as to style and sentiment. As one of the best Tamil translations of English books in respect of diction and idiom may be mentioned the *Bâlavyâpârikal,* or "Little Merchants," published by the Vernacular Text Society, Madras. P. Percival's collection of *Tamil Proverbs* (3rd ed , 1875) should also be mentioned.

The copper-plate grants, commonly called *Sâsanams,* and stone

inscriptions in Tamil, many of which have been copied and translated (*Archaeological Survey of Southern India*, vol. iv.; R. Sewell, *Lists of the Antiquarian Remains in the Presidency of Madras*, vols. i., ii.), are the only authentic historical records. (*See* also Sir Walter Elliot's contribution to the *International Numismata Orientalia*, vol. iii. pt. 2.) As early as the time of the Chinese traveller Hsüan Tsang, books were written in southern India on talipot leaves, and Albiruni mentions this custom as quite prevalent in his time (1031). It has not died out even at the present day, though paper imported from Portugal has, during the last three centuries, occasionally been used. Madras is now the largest depository of Tamil palm-leaf mss.; which have been described in Wilson's *Catalogue of the Mackenzie Collection* (Calcutta, 1828, 2 vols.), W. Taylor's *Catalogue* (Madras, 1857, 3 vols.), and Condaswamy Iyer's *Catalogue* (vol. i., 1861).

The art of printing, however, which was introduced in southern India at an early date, while it has tended to the preservation of many valuable productions of the ancient literature, has also been the means of perpetuating and circulating a deal of literary rubbish and lasciviousness which would much better have remained in the obscurity of manuscript. Dr. Burnell has a note in his *Elements of South Indian Paleography* (2nd ed., p. 44), from which it appears that in 1578 Tamil types were cut by Father João de Faria, and that a hundred years later a Tamil and Portuguese dictionary was published at Ambalakkâḍu. At present the number of Tamil books (inclusive of newspapers) printed annually far exceeds that of all the other Dravidian vernaculars put together. The earliest Tamil version of the New Testament was commenced by the Dutch in Ceylon in 1688; Fabricius's translation appeared at Tranquebar in 1715. Since then many new translations of the whole Bible have been printed, and some of them have passed through several editions.

The German missionary B. Ziegenbalg was the first to make the study of Tamil possible in Europe by the publication of his *Grammatica Damulica*, which appeared at Halle in 1716. Some time later the Jesuit father Beschi devoted much time and labour to the composition of grammars both of the vulgar and the poetical dialect. The former is treated in his *Grammatica Latino-Tamulica*, which was written in 1728, but was not printed till eleven years later (Tranquebar, 1739). It was twice reprinted, and two English translations have been published (1831, 1848). His *Sen-Tamil Grammar*, accessible since 1822 in an English translation by Dr. Babington, was printed from his own ms. (*Clavis humaniorum literarum sublimioris Tamulici idiomatis*) at Tranquebar in 1876. This work is especially valuable, as the greater portion of it consists of a learned and exhaustive treatise on Tamil prosody and rhetoric. (*See*, on his other works, Graul's *Reise*, vol. iv. p. 327.) There are also grammars by Anderson, Rhenius, Graul (in vol. ii. of his *Bibliotheca Tamulica*, Leipzig, 1855), Lazarus (Madras, 1878), Pope (4th edition in three parts, London, 1883–85), and *Grammaire française-tamoule*, by the Abbé Dupuis (Pondicherry, 1863). The last two are by far the best. The India Office library possesses a ms. dictionary and grammar "par le Rév. Père Dominique" (Pondicherry, 1843), and a copy of a ms. Tamil-Latin dictionary by the celebrated missionary Schwarz, in which 9,000 words are explained. About the like number of words are given in the dictionary of Fabricius and Breithaupt (Madras, 1779 and 1809). Rottler's dictionary, the publication of which was commenced in 1834, is a far more ambitious work. But neither it nor Winslow's (1862) come up to the standard of Tamil scholarships; the *Dictionnaire tamoul-français*, which appeared at Pondicherry in 2 vols. (1855–62), is superior to both, just as the *Dictionarium latino-gallico-tamulicum* (*ibid*, 1846) excels the various English-Tamil dictionaries which have been published at Madras.

TAMLUK, a subdivisional town of British India, in the Midnapore district of Bengal on the river Rupnarayan. Pop. (1921), 8,348. Under the name of Tamralipta, it was a seaport at which the Chinese Buddhist pilgrims embarked; it may also be identified with Tamalites noticed by Ptolemy as being on the river Ganges. The channel connecting the town with the sea survived till the 17th century, when the Portuguese had a settlement here, and then silted up. Tamluk is now 60 m. from the sea, and the ruins of the old city lie deep beneath river silt.

TAMMANY HALL. Quite as old as the U.S. Government, this powerful political organization in New York city has, with only occasional intermissions, not only ruled that city since the year 1800, but at times has exercised great influence in State administration and even in national affairs.

Its Origin.—Before the American Revolution groups proclaiming fealty to King George III. were organized in societies bearing the names of St. George, St. Andrew and St. David. To counter their aims the revolutionists formed associations called the Sons of Liberty or the Sons of St. Tammany. Tammany or Tammanend was an Indian chief noted for his wisdom, benevolence and love of liberty. In ridicule of the imported saints, revolutionists dubbed Tammany a saint. With the achievement of American independence the Sons of Liberty and the Sons of St. Tammany dissolved.

When the delegates of New York State met to adopt a Federal constitution, the discussions evidenced the existence of a unified aristocratic group. During the Revolution many estates owned by opponents of the American cause had been confiscated. But there remained some large estates in possession of families which either supported the Revolution or were not hostile. The proprietors of these estates, often vested with almost feudal powers, constituted the core of the aristocratic party. To resist these influences, William Mooney, an upholsterer in New York city, founded the Society of St. Tammany or Columbian Order, on May 12, 1789, a fortnight after the establishment of the National Government. His purpose was the creation of a society native in character and democratic in principle and action. Its officers were given Indian titles; the society's chief was Grand Sachem and his fellow chiefs Sachems. The democracy comprehended in Tammany's original period was not, however, that of later times. For more than three decades after its organization Tammany represented the middle-class opposed to the pretensions and power of the aristocratic party; it did not then represent the lower classes.

At first, the Society of St. Tammany was non-partisan in the sense that it had no distinct political affiliations but expressed its democratic sentiments in toasts and speeches at occasional banquets and displayed itself in parades. But when, in 1798, there was a division of conflicting forces into parties the Society of St. Tammany ardently supported the Republican (later called Democratic) Party, led by Thomas Jefferson. Realizing the effective political uses to which the society could be converted, Aaron Burr was largely instrumental in causing its change to an active political club opposed to the Federalist Party. Through various aides Burr controlled the Society of St. Tammany until his downfall after killing Alexander Hamilton in a duel in 1804. The society had an influential share in bringing about the democratic victory in the election of Thomas Jefferson as president of the U.S. in 1800. In the same year the society's leaders won election or obtained appointment to New York city municipal offices.

Tammany Hall Organized.—Caustic criticisms made by the opposition that a private society was engaging in politics resulted in a separation of social from political functions. In 1805 the Society of St. Tammany obtained from the legislature a charter incorporating it as a benevolent and charitable body to give relief to members and others. The Tammany Hall political organization was now created as an apparently distinct body. In reality the society's Sachems controlled the political mechanism; the leaders of the two organizations were either identical or the men directing

the political arm had their representatives as Sachems. The explanation of the Tammany society's control of the Tammany Hall political organization lay in the fact that the society has been continuously the owner of the Tammany Hall building In this capacity it has always had and still has the power of dispossessing any faction hostile to the Tammany Hall leaders. As the label of party regularity became binding upon a majority of voters, no faction thus evicted could properly claim to be the Tammany organization or any part of it This happened in 1828, 1838, 1853 and 1857 when the Sachems, as trustees of the building, excluded factions from meeting in Tammany Hall.

Until 1806 Tammany Hall remained an agitational political club, the New York city representative of the Republican, later termed Democratic, Party. In that year was begun a thorough organization of Democratic voters. The main features of this comprehensive plan were general, nominating, corresponding and ward committees In the general committee was vested the power of convening the party's meetings and of making all necessary arrangements for elections Composed originally of 30 members, this committee was gradually expanded until it had many thousands of members penetrating every section in the city

Tammany Hall's strength was greatly increased when, in 1820, it decided as a matter of policy to support a New York State constitutional amendment abolishing property qualifications for voting. Effective in 1822, this amendment brought a new and ever-increasing voting element into politics and generally into Tammany Hall. The change produced by manhood suffrage was not immediate. For some years more Tammany was led by bankers and merchants who used their power for self-enrichment The Workingmen's Party, in 1829, and its successor, the Equal Rights Party, organized in 1834, so successfully warred upon banker leaders and their colleagues that the general committee rid Tammany Hall of this element.

Gang Control and "Boss" Rule.—The period especially from 1846 onward was one in which heavy immigration, notably Irish, poured into New York city. Impecunious, and objects of religious and racial prejudice, numbers of the Irish, unable to get work, banded in street gangs Unlike other political parties, Tammany Hall welcomed immigrants, facilitated their naturalization and gave them relief. The astute, unscrupulous and engaging Fernando Wood organized the gangs as a political power within Tammany Hall, securing his own advancement as well as assuring Tammany the redoubtable support of men equally useful in overawing opposition, packing primaries or committing frauds at the polls. Wood had been a powerful but not a supreme leader. With the ascendency of William M. Tweed in 1867, Tammany Hall came under the sway of a single leader or boss. The son of a chairmaker, Tweed had won his way through ward politics, had been a member of "The Forty Thieves" board of aldermen in 1851–52, manipulating his unprincipled way to the rule of Tammany Hall Corruption reached its climax under Tweed when New York city was plundered of an amount conservatively estimated at $45,000,000 in direct spoliation, but ranging as high as $200,000,000 when reduced taxes and fraudulent bond issues are also considered Only $876,000 was ever recovered. Tweed died in gaol, but most of his confederates and the other looting beneficiaries retained their wealth Tammany Hall became a world-wide object of odium

Restored to Power.—For a time in popular disfavour, Tammany Hall, within three years after the exposures of the Tweed régime, was again in power in New York city. Succeeding Tweed as boss, John Kelly sagaciously induced Democrats who had been prominent in overthrowing Tweed to reorganize Tammany Hall. Superficial, this move in nowise affected the composition and characteristics of the Tammany organization at large. The real resuscitating factor was the attachment of New York city's tenement house masses to an organization the district leaders of which exercised a human relationship, coming into direct contact with them, treating them politically as equals, and giving a helping hand to those in want or trouble. This one large service outweighed all of the denunciations of Tammany by Republican business opponents who often had their own less spectacular but more insidious system of corruption. After Kelly's death in 1886, Richard Croker succeeded as Tammany Hall's boss, and he was followed by Charles F. Murphy in 1902. During this period many charges of Tammany corruption were made and proved. But these were perhaps no greater than the contemporary frauds and corruptions committed by financial, insurance and other corporations.

Tammany in Recent Years.—With the accession of Judge George W. Olvany to leadership of Tammany after Murphy's death in 1924, came evidence of a still more altered Tammany Hall Differing from his predecessors, Judge Olvany was a university graduate and lawyer, having served in the court of general sessions. In contrast to former or older crude district leaders, the new district leaders were also men of varying degrees of education. The force behind this changing Tammany was generally recognized to be that of Alfred E. Smith (*q.v.*), four times governor of New York and a leading Presidential candidate. On Mar. 16, 1929, Olvany suddenly resigned his leadership. Many interpreted this as meaning a loss of Smith's power and influence after his defeat in the national election of 1928. After a month's deadlock between the factions John F. Curry, a former ward leader of the old type, was elected to head the organization. Tammany definitely decided to retrench and confine its attention to municipal politics. Although since 1898 New York city has been extended to include five boroughs, Tammany Hall's organization has been confined to Manhattan and the Bronx. The Democratic organizations of other boroughs have been allied bodies. In Dec. 1927 The Tammany Society sold the Tammany Hall building on 14th street, which it had occupied since 1868, and bought a site for a new building at Union square, E. and 17th street, which was occupied on January 1, 1929

See Gustavus Myers, *The History of Tammany Hall;* "The New Tammany," *The Century Magazine,* Aug. 1926; Dennis Tilden Lynch, *Boss Tweed;* M. R. Werner, *Tammany Hall* (1928).

TAMMERFORS: *see* TAMPERE.

TAMMUZ, Sumerian, Babylonian and Assyrian god, who died and rose annually with dying and reviving vegetation, originally *Dumu-zi,* "the son who rises, goes forth (from the nether world)," but generally interpreted "faithful son." Philologically both interpretations are correct, and no Accadian commentary exists to explain which meaning was accepted by them The interpretation as "the son who rises," "the resurrected child," accepted in this article, is new and differs from all views held in the standard works on this cult. It is clear, however, that the main principle of this cult is the resurrection of the dying god, and the verb *zi* stands for the root *zig* to rise up, not *zid,* to be faithful (*See* S. Langdon, *Sumerian Liturgies and Psalms,* p 287, 17, *ušubba-za uziga-za,* "In thy fall and in thy resurrection.")

There are many titles of the youthful god, loved by his sister, the earth and heaven goddess, Innini (Ishtar), who descends yearly into Aralû (under-world) at the time of his death to bring him back to earth in her bosom Since he represents the mystery of life and death, as seen in the withering vegetation of the hot Mesopotamian summer, and the rapid renewal of its life at the season of the spring rains, Tammuz is the patron of flocks and irrigation as well as of vegetation. Titles such as god *Sipa,* the shepherd, *umun mirsi,* lord of the flood, god *Ab-ú,* father of vegetation, god *Zulumma,* god of the date palm, are not so old as those which reveal theological speculation concerning the brother, lover and husband of the earth mother. Theology gave rise to this, the most widely spread and profoundly religious aspect of West Asiatic and Egyptian religion (where it appears as the cult of Osiris and Isis). *Dumu-zi* appears in the oldest texts without a divine title, *c* 3200 B.C., and in Sumerian texts of Eannatum of Lagash (*c.* 2850 B.C), as god *Dumuzi-apsu,* "risen child of the deep," describing him as the son of the god of the nether sea of fresh waters, *Ea, Enki,* a title confined apparently to early Lagash, where he appears more often under the title Ningišzida, "Lord of the faithful tree," a title which developed into an independent deity. In the legend of Eridu, in which Adapa is sent to the gates of heaven for judgment because he had broken the wings of the south-wind, he found Tammuz and Ningišzida at the gate of heaven; they offered him bread and water of life, which he, on the advice of the water god of Eridu, refused and

thus lost immortality. Tammuz and Ningišzida appear to have been identified with the stars Castor and Pollux or, perhaps, Procyon and Sirius.

The liturgical wailings for Tammuz during the period of his sojourn in Aralû are numerous and describe every aspect of the theological doctrines concerning him. They are invariably composed in Sumerian, rarely with Accadian interlinear translation. These wailings occurred at midsummer, and the sixth month of the calendar at Lagash from the 28th to the 24th centuries is named the "month of the festival of Tammuz," corresponding to September if the year began near the spring equinox. There is a variant name for this month at Nippur called, "month of the mission of Innini," referring to her descent to Aralû in search of her departed lover. The Babylonians retained the old name of the fourth month and for some reason described it as the "month Tammuz," corresponding to July, retaining the name "month of the mission of Innini" for the sixth month (Elul). In this month (fourth) Tammuz is said to have been bound, and the liturgies speak of his having been drowned among flowers which were thrown upon him as he sank beneath the waves of the Euphrates. He is described as the shepherd who left his flocks, as the shepherds sat in the fields wailing for Tammuz.

There is a strange inconsistency in the hymns of these wailings concerning the relation of the mother goddess to her lover, Tammuz. In the early Sumerian texts she is his sister, but soon the Semitic view that she is his mother prevails. The two theories appear inconsistently together throughout the entire history of the cult. He is, however, invariably the husband and lover of the otherwise consistently described virgin goddess of love, Innini, Gestinanna, *Bêlit-sêri* (queen of the field of the lower world), and the cult is particularly associated with the great city Erech, home of the cult of Anu, the heaven god, and Innini. In all ceremonies connected with his cult his mother or sister is invariably associated with him, and it is the one aspect of Sumerian and Babylonian religion which may be described as universal and not largely confined to any local tradition. Badtibira, Pantibiblas of the Greek, near Erech, seems to have been the original seat of the cult, and in the Sumerian tradition of the ten pre-diluvian kings, the name of one at Badtibira is Dumuzisipa, "Tammuz the shepherd"; one of the names of Tammuz is Tibira. No great temple was built to him, and a few casual references to a temple of Tammuz at Umma, Ur, Lagash, Agade, clearly refer to shrines in the temple of the local deity reserved for the wailings and mystic ceremonies of the cult. Worship of Tammuz spread far beyond the lands to which the Sumerian religion was principally confined. Ezekiel speaks of it as firmly installed at Jerusalem in his time; it is mentioned in the Christian era in Mandean and Syriac literature, and survived among the Ssabeans at Harran as late as the middle ages. At Byblus, in Syria, he was identified with the West Semitic Adonis.

In astrology Tammuz was identified with Aries; in the magic rituals he is symbolized by a white kid, and he is also connected with the ram, which led to this astral identification. Under the title *Sibzianna*, "faithful shepherd of heaven," he was identified with Orion. During the period of deified king worship in the Dungi period of Ur, and in the time of the Isin dynasty, the deified kings habitually identified themselves with Tammuz and were worshipped as husbands of the mother goddess. For this reason it has been argued that the cult arose in prehistoric times, when a king was put to death as a sacrifice to the earth mother in order to secure the good will of the deity of vegetation. There is, however, no evidence for this in the earlier texts, and so far as Sumerian religion is concerned, the theory must be dismissed as unproved. He was held to be a god of healing, bestower of health, and one who, like all other deities, had power over the demons.

It is obvious that a cult which is based upon the death and resurrection of a propitiating god, and upon the love of a divine mother who wails for her son, has direct connection with the facts and the theological views based upon them, which gave birth to Christianity. But the form of the cult which apparently most directly affected the origins of Christianity is that in which Marduk of Babylon was identified with Tammuz. At the Nisan or new year festival at Babylon, Bêl (Marduk) was said to have been imprisoned in the lower world, and a priestess weeps at his sepulchre. A malefactor was slain with Bêl and they descend together to the land of darkness. Beltis, his wife, descends to hell to seek him, and Bêl's garments are given Ishtar (mother of Tammuz). Bêl was laid in a sepulchre, from which he soon comes forth. This Marduk transformation of the national Tammuz cult is only another effort of the priesthood of the capital to enlarge the worship and importance of the local cult. It obtained nowhere else in Babylonia and Assyria, and may be regarded as a true interpretation of what transpired regularly in the Tammuz cult itself. That the cult had direct influence upon the origins of Christianity cannot be denied, and the Greek cult of Adonis owes its essential content to the Sumerian Tammuz.

TAMPA, a city on the west coast of Florida, U.S.A., at the head of Tampa bay (Gulf of Mexico), 330 m. S.E. of Pensacola and 220 m. N.W. of Key West; a port of entry and the county seat of Hillsborough county. It is on Federal highways 41 and 92; has a municipal airport (240 ac.) connected with the Bay by a canal 500 ft. wide, to accommodate seaplanes; and is served by the Atlantic Coast Line and the Seaboard Air Line railways, 21 steamship lines, operating to both American coasts and foreign ports, and four motor-bus lines, covering Florida and adjacent territory and connecting with lines for New York and Chicago. Pop. 94,743 (20% negroes and about 20% foreign-born white) in 1925 (State census) and was estimated locally in 1928 (after the annexation of West Tampa and other territory) at 175,000.

The city lies at the mouth of the Hillsborough river, with the Ybor estuary on its eastern boundary, facing the islands in Hillsborough bay (the eastern arm of Tampa bay). The climate is delightful, with an average monthly mean temperature ranging from 60·6° F in January to 81·5° in August, an average annual precipitation of 53·13 in., and an average of 66% of the "possible sunshine" in the year. Tampa has been a resort since the '80s and with one exception the hotels are open the year round. It is a centre for tarpon fishing, and winter headquarters for the National Professional Polo Association. Tampa Bay hotel (the oldest one for tourists in the city) is owned and operated by the city. There is a municipal polo field, a municipal fishing pier and generous provision for all the usual sports and recreations. The Gasparilla Carnival is an annual event in February. About 100,000 visitors from the North stop in the city during the year. Between 1925 and 1928 extensive additions were made to the public school plant (according to a programme mapped out for the city by experts) bringing its total value to $12,000,000. Tampa ships more phosphate rock (1,534,266 tons in 1927) and manufactures more clear Havana cigars than any other city. Its water-borne commerce amounted to 4,170,262 tons in 1927, and customs receipts were $2,630,554. There are about 160 cigar factories. Tampa is an important distributing point for oil and gasolene, and has a large wholesale and retail trade. Bank debits in 1926 aggregated $921,-229,000. The city's assessed valuation for 1927 was $139,141,000. In 1927, after seven years under a commission-manager form of government, the city modified its charter to provide for a mayor with broad authority and a council of 12 district representatives.

Tampa was the name of the Indian village which de Narváez and de Soto found here in 1528 and 1539. The harbour, according to tradition, was a favourite resort of pirates, including the

picturesque Capt. José Gasparilla, whose memory is kept alive in the annual carnival. In 1823 the U.S. Government established a fort (Ft Brooke, an important base of supplies in the Second Seminole War; abandoned in 1860) and around it grew up a civil settlement In Nov. 1862, Tampa was taken by Federal gunboats. During the Spanish-American War (1898) it was the point of embarkation for the U.S troops that invaded Cuba. Theodore Roosevelt and his Rough Riders were encamped here for several weeks In 1880 the population was only 720. Between 1880 and 1890 the cigar industry was established, the first railroad reached the city, and the first hotel for tourists was built. By 1890 the city had a population of 5,532, which was shown to have increased to 15,839 in 1900, 37,782 in 1910, and 51,608 in 1920 The opening of the Panama Canal (1920) greatly enhanced the importance of the port, and within a few years its traffic was doubled. Tampa was one of the principal foci of the Florida "rush" of 1924–25. The city was incorporated in 1855.

TAMPERE, formerly Tammerfors, an industrial city of Finland in 61° 28′ N, 23° 45′ E., on the rapids connecting Lakes Näsi-järvi and Pyhä-järvi, and at a railway junction Pop. (1925) 51,717. It manufactures textiles, paper and leather goods.

TAMPICO, a city and leading port of Mexico, in the State of Tamaulipas, on the north bank of the Pánuco river, about 6 m. from the Gulf of Mexico. In summer the climate is hot and humid, although a sea breeze modifies the temperature somewhat. In winter the temperature falls to freezing on occasional days when "northers" blow down along the Gulf coast Tampico is almost surrounded by swampy lands and lagoons

The eastern and poorer part of the town stands on low ground only 2 or 3 ft above the river, and is subject to inundations However, a modern sewer system, up-to-date street paving and a better water-supply, constructed since the beginning of the century, have greatly improved the sanitary condition and reduced the death rate from epidemics The western part rises about 150 ft., consists largely of residential districts and is provided with still better sanitary equipment The business section is well built, largely of stone and brick, while many of the newer structures are of reinforced concrete and rise to six and seven storeys. The city is well supplied with gas and electric light.

Tampico has excellent transportation facilities, one railway line running north-north-west to Monterrey; another westward to San Luis Potosí, connecting there with the railway to Mexico City; a third short, but important line, leads southward, through the oil fields to Túxpam. Although a bar exists at the mouth of the Pánuco river, jetties have been built and the depth has been increased by dredging so that vessels drawing up to 33 ft can approach the water front of the city, while scows and other boats of light draught can go up the river for over 100 miles The Chijol canal, begun in 1901, affords a waterway 6 ft. deep and 25 ft wide for about 75 m. southward through the oil-fields to Túxpam. Modern port works, spacious enough to accommodate at the wharves 14 vessels at a time, steel sheds and warehouses, a union railway station within easy reach of the water front, and excellent equipment for loading oil tankers, make Tampico the most up-to-date harbour in Mexico.

Tampico owes its importance to the fact that four of the most productive oil-fields in the country (the Ebano, Pánuco, Huasteca and Túxpam) are situated within some 100 m. of its site. Until 1901 it was a second rate port, outlet of the fertile but relatively undeveloped hinterland, with a very bad reputation for health and sanitary conditions The rapid exploitation of petroleum resources resulted in a marked increase of population from about 10,000 in 1900, to 16,528 in 1910 and to 24,980 in 1921 while, if the neighbouring settlements connected with the port and oil business are included, the number at this last date would approach 100,000 For some years Tampico ranked as the greatest oil port in the world. Clusters of steel petroleum storage tanks extend along the river, particularly on the southern shore, from its mouth to a few miles above the city Pipe lines lead from the nearby fields, 68 of them centring in Tampico in 1922, while fleets of scows bring oil from farther up the river. Pipe lines and barges together are capable of transporting some 1,200,000 bbl. of oil daily from the fields to the port.

There are many foreigners (chiefly Americans) residing in the city and its suburbs and Tampico is the most Americanized of Mexican cities. It is essentially a bi-lingual port, its aspect is that of a busy American town. Up-river from the port agricultural activities have been stimulated, fruits, vegetables and grains being grown to supply the local food demands. Up-to-date commercial establishments, housed in modern structures, are stocked with American and European goods. Foreign banks afford facilities for the varied needs of the city. Hotels, clubs, restaurants and places of amusement are numerous and well served.

Besides those connected directly with the oil business, the industrial establishments of Tampico include many for the handling and repair of oil well machinery, yards for the building of river boats, an electric light and power plant, factories for making ice, clothing and fruit preserves, saw-mills, etc. In addition to petroleum, the exports include silver bullion (from San Luis Potosí, Aguascalientes, Torreón and Monterrey), ixtle fibre, sugar, hides, live cattle, cotton-seed cake, honey, fustic, sarsaparilla, coffee and copper ores.

TAMWORTH, municipality, Inglis county, New South Wales, Australia, on the Peel and Cockburn rivers, 285 m. by rail N. of Sydney Pop (1921) 7,150 It is the centre of several goldfields, at one of which, Bingera, diamonds are found. It is also the market of a pastoral and agricultural district. Brewing, malting, steam, saw and flour milling, coach building and the manufacture of boots and galvanized iron are its principal industries.

TAMWORTH, market town, municipal borough, Lichfield parliamentary division, Staffordshire, England, on the river Tame. The rural district of Tamworth is in the Tamworth division, Warwickshire. Pop. (1921) 8,030 It is 110 m. N E of London on the L M S. railway. The castle, situated above the Anker, is chiefly of the Jacobean period, but is enclosed by massive ancient walls. After being bestowed on the Marmions by William the Conqueror, the castle was for many years an important fortress. The town was formerly surrounded by a ditch of which traces only remain The church of St Editha (8th cent) was rebuilt, after the Danes burned it, by Edgar, who made it collegiate; the existing Decorated building was erected after a fire in 1345. The free grammar school, refounded by Edward IV, was rebuilt in 1677, and again in 1867. The charities include Guy's almshouses (1678), endowed by Thomas Guy, founder of Guy's hospital, London. Coal, fireclay and blue and red brick clay are dug in the neighbourhood; and there are also market gardens. In the town are a clothing factory, paper-mills, and manufactories of small wares.

Tamworth (*Tamwurda, Thamworth, Tomworth*) is situated near the Roman Watling street. It was burned by the Danes and restored in 913 by Aethelflead, who built the fort which was the origin of the later castle. The town was again destroyed by the Danes in 943. It is mentioned in Domesday. Tamworth was incorporated by Elizabeth in 1560 by letters patent, which state that it is an "ancient mercate town," and suggest that the charters have been lost or burned. The governing charter in 1835 was that of Charles II., incorporating it under the title of the bailiffs and commonalty of the borough of Tamworth in the counties of Stafford and Warwick Edward III. granted two fairs, still kept up in 1792, to be held respectively on St. George's day and the day of the Translation of St Edward; another ancient fair, in honour of St. Swithin, or perhaps originally of St. Editha, is still held (July 26). Tamworth sent two members to parliament from 1562 to 1885.

TANA, a lake of North-East Africa, chief reservoir of the Abbai or Blue Nile. Tana lies between 11° 36′ and 12° 16′ N. and 37° 2′ and 37° 40′ E., 5,690 ft. above the sea, on the northern portion of the Abyssinian plateau. Its greatest length is 47 m., its greatest breadth 44 m, and it covers approximately 1,100 sq m., having a drainage area, including the lake surface, of some 5,400 sq.m. The shores are well defined, generally flat, but at places the mountains descend somewhat abruptly into the water. Elsewhere the land rises in gentle undulations, except at

the mouths of the larger tributary streams, where are alluvial plains of considerable size. At the south-east end the lake forms a bay about 11 miles long, and from three to eight miles across. From this bay the Abbai issues. The whole coast-line is considerably indented and many narrow promontories jut into the lake. The island of Dek (eight m. long by four broad) is in the south-western part of the lake. Near it is the smaller island of Dega. Numerous islets fringe the shores.

Lake Tana is fed by three large rivers and by many petty streams. The chief tributary is the Little Abbai, which enters the lake at its south-west corner. This river, and the Abbai itself or Blue Nile which issues from the lake, are regarded as one and the same stream and a current is observable from the inlet to the outlet. Next in importance of the affluents are the Reb and Gumara, which run in parallel courses and enter the lake on its eastern side. The outlet of the lake is marked by openings in a rocky ledge, through which the water pours by two or three channels, in a succession of rapids, uniting within a couple of miles into one river—the Abbai with a width of 650 ft.

The average annual rainfall in the Tana catchment area is estimated at 3¼ ft., and the volume of water received by the lake yearly from this source and from affluents at about 6,572,000,000 of cubic metres. The average seasonal alteration of the lake level is not more than about 1½ metres.

Three technical missions have been sent by the British and Egyptian Governments conducted respectively by Mr. Dupuis (1903), Mr. Buckley (1916) and Mr. Grabham (1920–1) to report on the feasibility of utilizing the lake as a reservoir with the object of regulating the supply of water (3,500 million cu.m. in a normal year) discharged from the lake into the Blue Nile for irrigation needs in the Sudan and Egypt. As a result a scheme of works has been proposed, and it is estimated that these works, in addition to securing a more even distribution of water during the year, would by storing the surplus water in years of heavy rainfall form a reserve of 8,000 million cu.m. to tide over the deficiency in years of bad supply. The Abyssinian Government, however, has consistently opposed the project.

Tana has been identified with the *Coloe Palus* of the ancients, which was described by Ptolemy as a chief reservoir of the Egyptian Nile and the source of the *Astapos,* which was certainly the Blue Nile. In 1625 it was visited by the Portuguese priest Jeronimo Lobo, and in 1771 by James Bruce. It was formerly known by the name of Dembea.

See Nile and Abyssinia, and the authorities there cited. The British Blue Book, *Egypt,* No. 2, 1904, which contains a special report (with maps) upon Lake Tana. Also the most valuable *Report of the Mission to Lake Tana* (*1920–21*) issued by the Egyptian Ministry of Public Works in 1925. (C. F. R.)

TANA, a river over 500 m. long, in Kenya Colony, which gives its name to the Tanaland province of that British protectorate. Its sources are along the watershed close to the eastern wall of the eastern rift-valley, and it enters the Indian Ocean in 2° 40′ S., about 110 m. north of Mombasa. One series of its numerous headstreams traverses the Kikuyu plateau north of the Athi, others flow from Mount Kenya, all following a south-easterly direction until intercepted by the main stream which flows north-east until, when nearing the equator, it turns eastward afterwards sweeping southward to the sea. It receives tributaries only along its upper course but on entering the plain it flows along a tortuous course, has low banks, is in part forested and inundated at high water, but away from the river the country appears to consist of dry plains covered with mimosa scrub. The river frequently divides in its lower course, has many backwaters and has often changed its course, especially its place of entering the sea. It is navigable for 150 m. from its mouth. North of the Tana is the Ozi, a small river connected with the Tana by the Belazoni canal.

TANAGER, the name of birds of the family *Tanagridae,* allied to the *Fringillidae* (*see* Finch), and distinguished by their feebler conformation and more exposed nostrils. They are confined to the New World, and are specially characteristic of the tropical forests of Central and South America, only in a small proportion reaching Mexico, and four species breeding in the U.S.A.

The tanagers have been examined systematically by P. L. Sclater; he admits the existence of 375 species, which he arranges in 59 genera, forming six subfamilies, *Procniatinae, Euphoniinae, Tanagrinae, Lamprotinae, Phoenicophilinae,* and *Pitylinae.* These are of very unequal extent, for, while the first of them consists of but a single species, *Procnias tersa,* the third includes more than 200.

Nearly all are birds of small size, the largest barely exceeding a song-thrush. Most of them are remarkable for their gaudy colouring, and this is especially the case in those forming the genus *Tanagra.* Generally among the tanagers, both sexes are nearly alike in plumage. Insects, especially in the larval condition, and berries afford the greater part of their food. They have a pleasing song, and build a shallow nest, in which the eggs, generally three in number, and of a greenish-blue marked with brown and purple, are laid.

The scarlet tanager (*Piranga erythromelas*) nests in the eastern U.S.A., west to the Plains and north to New Brunswick and Manitoba, wintering in South and Central America. The male is scarlet, with black wings and tail; the female is olive green, lighter below, with dusky wings and tail. The song is reminiscent of the American robin, but is inferior.

The summer tanager (*P. rubra*) does not reach farther north than New Jersey and Kansas. The male is rosy red, the female olive-yellow above, dusky saffron below. The song is superior to that of *P. erythromelas.*

The remaining species, *P. ludoviciana,* the males of which are mostly yellow and black, with the head only red, does not appear eastward of the Missouri plains, and has not so northerly a range. Another species, *P. hepatica,* has shown itself within the limits of the United States. In all these the females are plainly attired.

TANAKA, GIICHI, Baron (1863–), Japanese statesman and general, born in Yamaguchi, graduated at the military cadet's school in 1886, and the staff college in 1892. He was minister of war in the Hara and Takahashi cabinets in 1918–21, and 1920. He became leader of the Seiyukwai Party in 1926. On the fall of the Wakatsuki government in April 1927, he formed a government himself taking the ministry of foreign affairs.

TANAQUIL, the Etruscan name of the wife of Tarquinius Priscus, or of one of his sons. After her immigration to Rome she is said to have received the name Gaia Caecilia. She was famous for her prophetic gifts. There was a statue of her as Gaia Caecilia in the temple of Sancus, which possessed magical powers. She was celebrated as a spinner of wool, and was supposed to exercise influence over Roman brides. Tanaquil and Gaia Caecilia are, however, really distinct personalities. The anecdotes told of Gaia Caecilia are aetiological myths intended to explain certain usages at Roman marriages.

See Livy, i. 34, 41; Pliny, *Nat. Hist.,* viii. 74, xxxvi. 70; Schwegler, *Römische Geschichte,* bk. xv. 8.

TANCRED (d. 1112), nephew of Bohemund and a grandson of Robert Guiscard on the female side, was the son of a certain *Marchisus,* in whom some have seen a marquis, and some an Arab (Makrizi). He took the Cross with Bohemund in 1096, and marched with him to Constantinople. Here he refused to take an oath of Alexius, escaping across the Bosporus in the disguise of a peasant; but after the capture of Nicaea he followed the example of the other princes, and became the man of Alexius. At Heraclea, in the centre of Asia Minor, he left the main body of the Crusaders, and struck into Cilicia, closely followed by Baldwin of Lorraine. He made himself master of Tarsus, and when he was evicted from it by the superior forces of Baldwin, he pushed further onwards, and took the towns of Adana and Mamistra. He joined the main army before Antioch, and took a great part in the siege. In the beginning of 1099 he was in the ranks of Raymund's army, but he soon left the count, like so many of the other pilgrims (*see* under Raymund); and he joined himself to Godfrey of Lorraine in the final march. After the capture of Jerusalem he went to Nablous, and began to found a principality of his own. He took part in the battle of Ascalon in August; and after it he was invested by Godfrey with Tiberias and the principality of Galilee, to the north of Naplous. In 1100 he attempted, without success, to prevent Baldwin of Lorraine (his old enemy in Cilicia)

from acquiring the throne of Jerusalem. Failing in this attempt, and being urgently summoned from the North to succeed Bohemund in the government of Antioch, he surrendered his smaller possessions to Baldwin. He acted as regent in Antioch until 1103, when Bohemund regained his liberty. He regained the Cilician towns for Antioch (1101), and recaptured Laodicea (1103); he imprisoned Raymund of Toulouse, and only gave him his liberty on stringent conditions; and he caused the restoration of the deposed patriarch of Jerusalem, Dagobert, if only for a brief season, by refusing to aid Baldwin I. on any other terms. When Bohemund was set free, Tancred had to surrender Antioch to him. In 1104 he joined with Bohemund and Baldwin de Burg (now count of Odessa in succession to Baldwin of Lorraine) in an expedition against Harran, in which they were heavily defeated, and Baldwin was taken prisoner Tancred, however, profited doubly by the defeat. He took over the government of Edessa in Baldwin's place; and in 1105 Bohemund surrendered to him the government of Antioch, while he himself went to Europe to seek reinforcements. Ruler of the two northern principalities, Tancred carried on vigorous hostilities against his Mohammedan neighbours, especially Ridwan of Aleppo; and in 1106 he succeeded in capturing Apamea. In 1107, while Bohemund was beginning his last expedition against Alexius, he wrested the whole of Cilicia from the Greeks; and he steadfastly refused, after Bohemund's humiliating treaty at Durazzo in 1108, to agree to any of its stipulations with regard to Antioch and Cilicia To the hostility of the Mohammedans and the Greeks, Tancred also added that of his own fellow Latins. When Baldwin de Burg regained his liberty in 1108, it was only with difficulty that he was induced to restore Edessa to him. But it was against the emirs of Northern Syria that his arms were chiefly directed; and he became the hammer of the Turks. He died in 1112, leaving the government to his brother-in-law, Roger de Principatu, until such time as Bohemund II. should come to his inheritance.

Bibliography.—Tancred's *Gesta* were recorded by Ralph of Caen, who drew his information from Tancred's own conversation and reminiscences. Kugler has written a work on *Bohemund und Tancred* (Tübingen, 1862); and Tancred's career is also described by Rey, in the *Revue de l'Orient Latin*, iv. 334–340

TANCRED (d. 1194), King of Sicily, an illegitimate son of Roger the eldest son of King Roger II, was crowned in January 1190 in succession to William II. (*q.v.*). He was supported by the chancellor Matthew d'Ajello and the official class, while the rival claims of Roger II's daughter Constance and her husband, Henry VI, king of the Romans and emperor, were supported by most of the nobles. Tancred was a good soldier; but he was ill-supported in his task of maintaining the Norman kingdom, faced with general apathy, threatened by a baronial revolt, and menaced by Richard Coeur-de-Lion, at Messina, 1190. Henry, skilfully winning over Pisa, Genoa and the Roman Commune, isolated Tancred and intimidated Celestine III, who, on April 14, 1191, crowned him emperor at Rome. He, however, failed to capture Naples in August and retired north, leaving garrisons along the frontiers of the Regno. Tancred now sought to win over the towns by extensive grants of privileges, and at Gravina (June 1192) was recognized by the pope, whose ineffectual support he gained by surrendering the royal legateship over Sicily. In 1192 and 1193 he successfully opposed the Apulian barons, but his death at Palermo (Feb. 20, 1194) a few days after that of Roger, his son and joint-king, made Henry's path clear

TANDY, JAMES NAPPER (1740–1803), United Irishman, born in Dublin in 1740, was a prominent reformer and supporter of Lucas and Grattan. He first won popularity by his attacks on municipal corruption and his proposal to boycott English goods in retaliation for the restrictions imposed on Irish commerce. In 1780 Tandy was expelled from the Dublin volunteers (*see* Flood, Henry), but he continued his revolutionary agitation, and in 1791 co-operated with Wolfe Tone in founding the Society of United Irishmen, of which he became the first secretary. A challenge sent to the attorney-general resulted in his imprisonment (1792), but on his release Tandy assisted in raising two battalions of a "national guard," which were suppressed. He then fled to America, and in 1798 proceeded to France, where he joined a number of Irish refugees. Having gained the ear of the French Government, Tandy was given command of a corvette, a small force of men, and a quantity of arms for distribution in Ireland. Arriving at Donegal, however, he learnt that Humbert's expedition had failed, and he thereupon fled to Hamburg. The refugees were surrendered on a peremptory demand from the British Government. Condemned to death, he was finally reprieved owing it is said to Bonaparte's intercession.

Tandy's exploits completely captured the popular imagination, and he is still remembered as the hero of the "Wearing of the Green." In France, where his release was regarded as a French diplomatic victory, he was received in March 1802, as a person of distinction; and when he died, on Aug 24, 1803, his funeral was attended by the military and an immense number of the civil population.

Barry O'Brien, 2 vols (London, 1893); W J. Fitzpatrick, *Secret Service under Pitt* (London, 1892); Sir Richard Musgrave, *Memoirs of Rebellions in Ireland*, 2 vols. (Dublin, 1802); J A. Froude, *The English in Ireland in the Eighteenth Century*, 3 vols. (London, 1872–74); *Castlereagh Correspondence*, i., ii.; *Cornwallis Correspondence*, ii, iii.

TANEGA-SHIMA, an island lying to the south of Kyushu, Japan, in 30° 50′ N and 131° E., 36½ m long and 7¼ m broad at its widest part. It is a long low stretch of land, carefully cultivated, and celebrated as the place where Mendez Pinto landed when he reached Japan in 1543.

TANEIEV, SERGIUS (1856–1915), Russian composer and theorist, was born on Nov. 13, 1856, in the Vladimir government He studied under Nicholas Rubenstein and Tschaikowsky at the Moscow conservatoire. After a short career as a concert pianist he went back to Moscow as professor of instrumentation, then first professor of pianoforte and, in 1885, director. He died at Moscow on June 15, 1915. His published works include a symphony, five string quartets, a dramatic work, *Orestes* (performed in St Petersburg 1895), a cantata, *John of Damascus*, and choruses for male voices and for mixed voices. He also wrote a treatise on counterpoint.

TANEY, ROGER BROOKE (1777–1864), American jurist, was born in Calvert county, Md, March 17, 1777. He graduated from Dickinson college, Carlisle, Pa, in 1795, and began studying law at Annapolis in 1776. He served in the State Senate in 1816–21, was attorney general of Maryland in 1827–31; and in July 1831 entered President Jackson's cabinet as attorney general of the United States. He was the President's chief adviser in the attack on the U.S. Bank, and was transferred to the treasury department in Sept. 1833, for the special purpose of removing the Government deposits. As a result, the Senate refused to confirm his appointment as secretary of the treasury.

On Dec. 28, 1835, he was nominated chief justice of the U.S. Supreme Court. After strong opposition, the nomination was confirmed on March 15, 1836. During President Jackson's administration (1829–37), the personnel of the supreme bench was entirely changed. Five of the seven judges in 1837 were his appointees. The majority of them were Southerners who had been educated under democratic influences. As a result, the State sovereignty influence was occasionally manifest, as for example, in the opinion (written by Taney) in the *Dred Scott* case (1857, 19 Howard, 393) that Congress had no power to abolish slavery in territory acquired after the formation of the National Government. Judge Taney died Oct. 12, 1864.

An authoritative biography is Samuel Tyler's *Memoir of Roger Brooke Taney* (1872).

TANGA, a seaport of Tanganyika Territory, East Africa, lying opposite the island of Pemba in 5° 6′ S., 39° 7′ E. Population about 10,000, including (1928) 431 whites. The town is regularly laid out on elevated ground on the southern shore of Tanga bay, amid coconut groves and avenues of mango trees. The harbour, which is commodious, is entered by a broad but tortuous channel five to eight fathoms deep. Tanga is the ocean terminus of a railway to the Usumbara highlands and Kilimanjaro. A motor road (130m. long) connects it with Mombasa.

At one time part of the sultanate of Zanzibar, Tanga passed into German possession in 1888. In 1914 a British force from India landed in the bay and attempted to capture the town. It suffered heavy losses and was compelled to re-embark. It was not until July 1916 that the place was occupied by the British, the Germans having meanwhile been defeated by Gen. Smuts.

TANGANYIKA, a vast lake in East-Central Africa, the longest freshwater lake in the world, measuring about 450 m. with a general breadth varying from 30 to 45 m., and an area of about 12,700 sq.m. It lies at an altitude of about 2,536 ft., is 4,708 ft. deep, therefore its floor is 2,172 ft. below sea-level. After Lake Baikal this is the deepest freshwater lake in the world. It occupies the southern end of the great western rift-valley which terminates suddenly at its southern point, but the line of depression is continued south-eastward through Lakes Rukwa and Nyasa, from which Tanganyika is separated by the Ufipa plateau. Another branch of the rift-valley passes south-westward into the Eastern Congo, branching from the northern end of the lake. North of Tanganyika the valley is suddenly interrupted by a line of young eruptive ridges, which dam back the waters of Lake Kivu (*q.v.*) but have recently been cut through (in about the year 1906) by the outlet of that lake, the Russisi which enters Tanganyika by several mouths at its northern end. The flat plain traversed by the lower Russisi was evidently once a portion of the lake floor. Tanganyika has been formed by the subsidence of a long narrow tract of country relatively to the surrounding plateaux which fall to the lake in abrupt cliffs, some thousands of feet high in places. The geological formations thus exposed show that the plateaux are composed of a base of Archaean gneisses and schists, overlain by enormous deposits of unfossiliferous red sandstones, conglomerates and quartzites (the Tanganyika Sandstones), which reach 3,000 ft. in thickness at the south end of the lake. They are almost certainly Archaean in age. The formation of the rift-valley dates from late Tertiary times. Besides the plain to the north a considerable area near the Lukuga outlet was once covered by Tanganyika. Although drinkable, the water of the lake seems at times at least to be very slightly brackish, and it was supposed by some that no outlet existed until in 1874, Lieutenant Cameron showed that the surplus water was discharged periodically towards the Upper Congo by the Lukaga river, about the middle of the west coast. Observations during the last 50 years indicate that the level of the lake frequently changes but these alterations are probably due only to fluctuations in rainfall.

The lake is fed by a number of rivers and small streams, but is by no means the centre of a large drainage area. The Malagarasi is the largest feeder. The lake is subject to occasional storms which leave a heavy swell and impede navigation.

Vegetation is generally luxuriant, and forest clothes portions of the mountain slopes. The lake lies on the dividing line between the floral regions of East and West Africa, and the oil-palm characteristic of the latter is found on its shores. The largest timber tree is the *mvule,* which attains vast dimensions. The more level parts of the shores have a fertile soil and produce a variety of crops, including rice, maize, manioc, sweet potatoes and sugar-cane. The waters display an abundance of animal life, crocodiles and hippopotami occurring in the bays and river mouths, which are also the haunts of water-fowl of many kinds. Fish are also plentiful. Various sections of the Bantu division of the negro race dwell around the lake, those on the west and south-west showing the most pronounced negro type, while the tribes on the east exhibit some intermixture with representatives of the Hamitic stock, and (towards the south) some trace of Zulu influence. The surrounding region has been overrun by Arabs and Swahili from the East African coast.

The lake was first visited in 1858 by Burton and Speke who reached Ujiji, which was the spot where in 1871 Dr. Livingstone was found by Stanley. The southern half of the lake was first circumnavigated by Lieutenant V. L. Cameron in 1874, and the whole lake by Stanley in 1876.

In the partition of Africa among the European powers the shores of Tanganyika were shared by Belgium, Great Britain and Germany, Great Britain holding the southern extremity, Germany the east and Belgium the west. After the World War the German portion became part of the British mandated territory of Tanganyika whilst Belgium extended her boundaries to include the mountains of Urundi on the north-east of the lake shore.

The chief towns on the lake are Sumbu, Niamkolo, Kasango, Ujiji and Kigoma (all British), Usumbura, Uvira, Albertville, Vua, Baudouinville and Moliro (all Belgian). Steamers ply on the lake traversing its length in about four days, the best harbours being at Kasanga, Kigoma, Usumbura and Albertville. The East African Central railway from Dar-es-Salaam terminates at Kigoma, whilst a railway passes down the Lukuga valley from Albertville.

Cunnington's expedition in *Proceedings of the Zoological Society* 1906, etc.; *Journal of the Linnean Society,* 1907, and official reports of the Tanganyika Territory (Annual).

TANGANYIKA TERRITORY, a country of East Central Africa. It is bounded east by the Indian ocean, south by Portuguese East Africa, south-west by Nyasaland, Northern Rhodesia, west by the Belgian Congo, north-west by Ruanda-Urundi and Uganda, north-east by Kenya Colony. It includes Mafia island. The area is about 365,000 sq.m. From 1884 to 1919 the Territory, together with the provinces of Ruanda and Urundi formed German East Africa. Since 1919 Tanganyika Territory has been administered under mandate by Great Britain. Ruanda-Urundi (*q.v.*) is under Belgian mandate.

Physical Features.—The coast extends from the mouth of the Rovuma in the south to the Umba river in the north. It is chiefly composed of coral, is little indented, and is generally low, partly sandy, partly rich alluvial soil covered with dense bush or mangroves. Where the Arabs had settlements the coco-palm and mango tree introduced by them give variety to the vegetation. The coast plain is from 10 to 30m. wide and 620m. long; it is bordered on the west by the precipitous eastern side of the interior plateau of Central Africa. This plateau, considerably tilted from its horizontal position, attains its highest elevation north of Lake Nyasa (*see* Livingstone Mountains), with heights up to 9,000 or more feet and a mean altitude of about 3,000 to 4,000 feet. From this region the country slopes towards the north-west. A deep, narrow gorge, the so-called "eastern rift-valley," traverses the middle of the plateau in a meridional direction. In the north it spreads into several side valleys, from one of which rises the extinct volcano Kilimanjaro (*q.v.*), the highest mountain in Africa (19,321ft.). Its glaciers send down a thousand rills which combine to form the Pangani river. About 40m. west of Kilimanjaro is Mount Meru (14,955ft.), another volcanic peak, with a double crater. South-east of Mount Kilimanjaro are the Pare mountains and Usambara highlands, separated from the coast by a comparatively narrow strip of plain. To the south of the Usambara hills, and on the eastern edge of the plateau, are the mountainous regions of Nguru (otherwise Unguru), Useguha and Usagara. The southern half of Victoria Nyanza and the eastern shores, in whole or in part, of Lakes Tanganyika and Nyasa, are in Tanganyika Territory. Lake Rukwa (*q.v.*), north-west of Nyasa, is presumably only the remnant of a much larger lake. Its extent varies with the rainfall of each year. North-west of Kilimanjaro is a sheet of water known as the Natron lake, from the mineral alkali it contains.

The country is well watered, but, with the exception of the Rufiji, the rivers, save for a few miles from their mouths are unnavigable. The largest streams are the Rovuma and Rufiji (*q.v.*), both rising in the central plateau and flowing to the Indian ocean. Next in importance is the Pangani river, which, as stated above, has its head springs on the slopes of Kilimanjaro. Flowing in a south-westerly direction, it reaches the sea after a course of some 250 miles. Into Victoria Nyanza are emptied, on the east, the waters of the Mori and many smaller streams; on the west, the Kagera (*q.v.*), besides smaller rivers. Into Tanganyika flows the

Malagarasi, a considerable river with many affluents, draining the west-central part of the plateau. The Kalambo is a comparatively small stream which enters the south-east end of Lake Tanganyika (marking the frontier with Northern Rhodesia). Not far from its mouth there is a magnificent fall, a large volume of water falling nearly 900ft. sheer over a rocky ledge of horse-shoe shape. So great is the height that the river only reaches the bottom of the falls in the form of spray. Of the streams entering Nyasa the chief are the Songwe and the Ruhuhu.

Mafia island lies off the coast immediately north of 8° N. It has an area of 200 sq miles. The island is low and fertile and extensively planted with coconut palms. It is continued southwards by an extensive reef, on which stands the chief settlement, Chobe, on a shallow creek.

Geology.—The narrow foot-plateau of Kenya Colony broadens out to the south of Bagamoyo to a width of over 100 miles. This is covered to a considerable extent by rocks of recent and late Tertiary ages. Older Tertiary rocks form the bluffs of Lindi Cretaceous marls and limestones appear at intervals, extending in places to the edge of the upper plateau, and are extensively developed on the Makonde plateau. They are underlain by Jurassic rocks, from beneath which sandstones and shales yielding *Glossopteris browniana* var. *indica,* and therefore of Lower Karroo age, appear in the south, but are overlapped on the north by Jurassic strata. The central plateau consists almost entirely of metamorphic rocks with extensive tracts of granite in Unyamwezi

The volcanic plateau of Kenya Colony extends over the boundary in the region of Kilimanjaro. Of the sister peaks, Kibo and Mawenzi, the latter is far the oldest and has been greatly denuded, while Kibo retains its crateriform shape intact. The rift-valley faults continue down the depression, marked by numerous volcanoes, in the region of the Natron lake and Lake Manyara; while the steep walls of the deep depression of Tanganyika and Nyasa represent the western rift system at its maximum development

Fossil remains of saurians of gigantic size have been found in the Tendagura hills and other parts of the Lindi district, one thigh bone measures 6ft 10 in., the same bone in the *Diplodocus Carnegii* measuring only 4ft. 11in. The examination of the sites begun by the Germans in 1909 was continued by the British, interesting discoveries being made in 1924.

Climate.—The warm currents setting landwards from the Indian ocean bring both moisture and heat, so that the coast has a higher temperature and heavier rainfall than the Atlantic seaboard under the same parallels of latitude. The mean temperature on the west and east coasts of Africa is 72° and 80° Fahr. respectively, the average rainfall in Angola 36 in., in Dar-es-Salaam 60 inches. On the Swahili coast the south-east monsoon begins in April and the north-east monsoon in November Besides the coast lands, three other climatic zones may be distinguished, as follows, though there are many local variations: (1) a hot and moderately dry zone from 300 to 2,000 ft high between the lowlands and the central plateau; (2) the central plateau zone, between 2,000 and 4,000 feet. Here rainfall is lower—an average of 32 inches a year at Tabora—the air dry and hot with great daily and seasonal variations; (3) a semi-temperate zone in regions over 5,000 feet. On the highest regions the climate is almost European, the nights being sometimes exceedingly cold. Two highland areas have climatic conditions permitting European settlement The first is the Usambara hills together with the Moshi and Arusha districts of Kilimanjaro; the second, and larger, area stretches from Iringa on the central plateau south-west to Lake Nyasa This area is known as the south-western highlands. In the country generally there are two rainy seasons, the "long rains" from February or March, and lasting two or three months, and the "lesser rains" in October and November.

Flora and Fauna.—The coast plains are covered by a rich tropical bush, in which the mangrove is very prominent. Coco-palms and mango trees have been planted in great numbers, and also many varieties of bananas. The river banks are lined with belts of dense forest, in which are useful timber trees The *Hyphaene* palm is frequent, as well as various kinds of gum-producing mimosas. The slopes of the plateau which face the rain-bringing monsoon are in some places covered with primeval forest, in which timber is plentiful. The silk-cotton tree (*Bombax ceiba*), miomba, tamarisk, copal tree (*Hymenaea courbaril*) are frequent, besides the rubber tree (*Landolphia florida*), sycamores, banyan trees (*Ficus indica*) and the deleb palm (*Borassus aethiopium*). The plateau is partly grass land without bush or forest, partly steppe covered with mimosa bush, which sometimes is almost impenetrable.

Tanganyika is rich in all kinds of antelope, and the elephant, rhinoceros and hippopotamus are still plentiful in parts. Characteristic are the giraffe, the chimpanzee and the ostrich. Buffaloes and zebras occur in two or three varieties. Lions and leopards are found throughout the country. Crocodiles are numerous in all the larger rivers. Snakes, many venomous, abound. Of birds there are comparatively few on the steppe, but by rivers, lakes and swamps they are found in thousands. Locusts occasion much damage, and ants of various kinds are often a plague The tsetse fly (*Glossina morsitans*) infests several districts; the sand-flea has been imported from the west coast. Land and water turtles are numerous

Inhabitants.—There are in all some 75 distinct negro tribes in the country. Two or three tribes, such as the Wahi of Lake Eyasi, are supposed to trace descent from a pygmy-like people, who are thought to have been the earliest inhabitants of the country. But what may be called the indigenous population consists of the older or primitive Bantu races. These tribes have been subject to the intrusion from the south of more recent Bantu folk, such as the Yao, belonging to the Ama-Zulu branch of the race, while from the north there has been an immigration of Hamito-Negroid peoples. Of these the Masai and Wakuafi are found in the region between Victoria Nyanza and Kilimanjaro. The Masai (*q.v.*) and allied tribes are nomads and cattle raisers. An Hamitic race, the Bahima (Hima or Huma), form the aristocratic class in the district around the south-west shores of Victoria Nyanza, and under Bahima kings Karagwe was formerly a powerful state The Bantu tribes are in general peaceful agriculturists, though the Bantus of recent immigration retain the warlike instincts of the Zulus. The most important group of the Bantus is the Wanyamwezi (*see* UNYAMWEZI), divided into many tribes. They are spread over the central plains, and have for neighbours on the south-east between Nyasa and the Rufiji, the Wahehe. The Wangoni (Angoni), a branch of the Ama-Zulu are widely spread over the central and Nyasa regions The Wasambara have given their name to the Highlands between Kilimanjaro and the coast. The Swahili (*q.v.*) inhabit the seaboard. Arabs, with some Persians and Indians, have long been settled on the coast.

BY COURTESY OF THE MARTIN JOHNSON AFRICAN EXPEDITION CORP

AN IKOMA HUNTER WITH POISONED ARROWS THAT PARALYZE THE ANIMAL BUT DO NOT MAKE THE FOOD UNFIT TO EAT

In 1928 there were some 4,500 European inhabitants, of whom more than half were British. the others were of many nationalities including a considerable Greek element and some 300 Germans. There were over 10,000 British Indians, and about 1,000 Goanese. The Arabs numbered about 4,000. The natives are estimated to number approximately 4,107,000. Of this number 1,500,000 live in the contiguous districts of Mwanza, Bukoba and Tabora, *i e*, the north-west part of the territory.

Many different dialects are spoken by the Bantu tribes, Kiswahili being the most widely known. (*See* BANTU LANGUAGES.) The great majority of the natives are pagans, but most of the Swahili are Mohammedans, while Protestant and Roman Catholic missions have gained a considerable number of converts.

Chief Towns.—The principal seaports are Tanga and Dar-es-Salaam. These and Bagamoyo and Kilwa are separately noticed. Pangani (pop. about 3,500), at the mouth of the river of the

same name, serves a district rich in tropical products. Sadani is a smaller port midway between Pangani and Bagamoyo, Lindi (10° 0′ S., 39° 40′ E.) is 80 m. N. of Cape Delgado. Lindi (Kiswahili for The Deep Below) bay runs inland 6 m. and is 3 m. across, affording deep anchorage. Hills to the west of the bay rise over 1,000 feet.

The chief inland towns are Tabora, Korogwe, Moshi, Mrogoro, Kilossa, Dodoma and Iringa. Korogwe is in the Usambara hills, on the north bank of the Pangani river, and 52 m. by railway from Tanga. Moshi (white pop. about 300), on the south slopes of Kilimanjaro and 219 m. by rail from Tanga, is the centre of large coffee plantations. Mrogoro is 130 m. west of Dar-es-Salaam, and is the first important station on the railway to Tanganyika. Kilossa and Dodoma are farther inland on the same railway. Iringa is the centre of the southern highlands. Tabora (*q.v.*) occupies an important position on the central plateau, being the meeting place of many trade routes. It is connected by railway with Dar-es-Salaam, with Kigoma, on Lake Tanganyika, and also (since 1928) with Mwanza, the chief port on the southern shores of Victoria Nyanza. Bukoba is on the western shore, and Schirati on the eastern shore of Victoria Nyanza. On Tanganyika and near Kigoma is Ujiji (*q.v.*).

Economic Progress and Trade.—Probably no other part of Africa suffered as much as did Tanganyika Territory from the ravages of the World War, and as regards economic development almost everything had to be re-created by the British authorities, whose first task in this department was the reconditioning of the railways. It was not until 1925 that the railways paid their way. Meanwhile the sisal, coffee and cotton and rubber plantations in Usambara, Para and elsewhere, which had been owned by Germans, passed into the hands of British, Indians and Greeks. It may be noted that under the terms of the mandate no discrimination against Indians could be made in Tanganyika, which thus differed from Kenya Colony. Changed world conditions—chiefly the development of plantation rubber in the East—rendered it useless to try and revive the rubber industry, but the other products, in especial sisal hemp, yielded good returns. The European and Indian planters were not alone in cultivating coffee and cotton. The production of these crops, especially cotton, by the natives on their own account was encouraged by the Administration and by the 1924–25 season, some 75% of the cotton exported was direct native production.

Sisal hemp produced is of the highest grade; the bulk of it is grown in the drier parts of the coast belt. This industry, requiring considerable capital outlay, is in the hands of Europeans, and each factory producing hemp requires at least 2,000 acres of sisal under cultivation. The industry owed its foundation to the Germans, and they devoted great attention to it. Up to 1924 the planters were, in the main, still using pre-war German machinery. Other agricultural or sylvan crops of note are copra, groundnuts, and maize. The coconut plantations from which the copra is obtained are found chiefly on the coast and in Mafia island, and most of them are owned by the Arabs. Other products exported include ivory, beeswax, gums and resins, gum-copal, rice, ghee and mangrove poles. For all matters connected with the development of the land the Biological and Agricultural Institute at Amani, in the Usambara hills, is of great value. Founded by the Germans in 1902, it is now maintained as an institute for the whole of East Africa. Stock raising is one of the main assets of the country, and hides and skins are an important item in the exports. Unfortunately the tsetse fly has laid large areas waste. There are 4,300 sq.m. of forests. Of this area over 3,700 sq.m. are State reserves.

The minerals worked include mica—widely distributed—gold and diamonds. Cassiterite (tin-ore) is found in the Bukoba district; coal, iron, copper and lead are also found, but are not worked. The chief gold deposits are in the Mwanza district, where is also a diamondiferous area, while further south, near Shinyanga, is another diamond field. Mica and gold were mined during the German occupation: diamond mining began in 1926, and at the same time the Bukoba tinfields were being worked. It was not until 1925 that trade recovered to the level of 1913 (the last normal year under German rule). In 1922 the trade figures were: Imports £1,386,000; exports £1,300,000; re-exports £141,000 (mostly transit trade from the Belgian Congo). In 1926 domestic exports were valued at £3,025,000 and the re-exports at £235,000, while trade imports totalled £3,597,000. Cotton piece goods, the chief import, came chiefly from Great Britain, India and Japan, and those countries took the raw cotton exported (25,000 bales in 1927). In 1927 coffee exports, mostly to France and Italian East Africa, totalled 6,595 tons, and sisal (mainly to Belgium and Great Britain) 33,000 tons. The diamond production was 18,095 carats (valued at £102,000).

Communications.—One of the great handicaps to development was the lack of adequate means of communication. The Germans had built two railway lines, one from Tanga to Moshi (219 m. long) which served the important plantations in Pare, Usambara and the slopes of Kilimanjaro—and Tanga up to 1929 had a bigger trade than Dar-es-Salaam—the other 773 m. long from Dar-es-Salaam to Kigoma on Lake Tanganyika. This is known as the Central railway. It was not until 1924 that financial conditions allowed the undertaking of any new work. In that year a line was begun northward from Tabora, on the Central railway. This line, which passes through the rich Shinyanga cotton belt, reached Mwanza, on Lake Victoria, in 1928. It is 238 m. long and serves also the diamond and gold fields in the district. It also offers an alternative route (to that from Mombasa) to Uganda. Another short railway was built from Moshi to Arusha, and there is a 90 m. line in the Lindi district. Schemes were put forward in 1924 for linking the Tanga and the Central railways, and for a line from the Central railway through the south-western highlands—where European settlement had begun—to Lake Nyasa or Rhodesia. They remained in the proposal stage in 1929. Over 25,000 m. of roads were built, on which motor traffic is possible in the dry season; they are nearly all impassable in the rains. On Lake Tanganyika there are Belgian and British steamer services, the chief traffic being with the Belgian side of the lake. At Mwanza and Tabora are aerodromes, but there was up to 1928 no regular air service. The Tanga railway is linked to the Kenya and Uganda railway by the Kahe-Taveta-Voi branch; otherwise Tanganyika Territory has no railway connection with the neighbouring British lands. There is wireless communication with the Belgian Congo, telegraphic connection by land wires with South Africa, and a cable from Dar-es-Salaam to Zanzibar. Communication from Tanganyika ports is maintained by several lines. Mails from London to Dar-es-Salaam take about three weeks in transit.

Administration, Education and Revenue.—The territory is governed on the lines of a British Crown Colony. The governor, who is responsible to the Colonial Office in London, is aided by an executive council and, since 1926, by a nominated legislative council. The ancient tribal organization of the natives under chiefs of their own race—largely broken up under German rule—has been restored as far as possible under the supervision of European administrators. The chiefs, often bearing the title of sultan, are executive officers and have their own treasuries. Native courts have limited civil and criminal jurisdiction (Proclamations of 1920 and 1925). Domestic slavery had been permitted by the Germans to continue, but they had decreed the freedom of all slaves born after 1905. In 1923 the British administration abolished the status of slavery, which no longer exists in Tanganyika in any form. Neither does the administration assist in the recruitment of labour for private enterprises. From 1924 onward effective steps were taken to provide education for the natives in addition to that given by the missionary societies. In the government schools instruction is in hygiene, agriculture and industries as well as literary and moral; at Dar-es-Salaam, Tanga, Tabora, Bukoba and other places are central schools where, among other things, natives are trained for posts in an African Civil Service. There is a native teachers' training centre at Mpapua. Instruction is given in Kiswahili and English; in mission schools instruction is generally given in the vernacular. Up to 1925 there were no government schools for European or Indian children, but a grant was made to the schools of the Dutch speaking settlers

at Arusha

Revenue is obtained chiefly from import duties and the native house, hut and poll tax (6/– to 12/– a year), about half the revenue being paid by natives The Customs tariff is similar to but not identical with that of Kenya and Uganda. Revenue which for 1919–20 was £669,000 had increased to £1,315,000 in 1923–24, the corresponding figures for expenditure being £790,000 and £1,901,000 To that time there has been a deficit of £761,000 on the working of the railways, besides £503,000 spent in capital and extraordinary expenditure upon them. Commercial depression, the forced change in the currency from rupees at 15 to the £ to florins and then shillings—the rupees (German and Indian) being redeemed at 2/– —added to the cost of restoring the devastated regions, had reacted unfavourably on revenue. But from 1923 an improvement set in and soon became marked. The revenue for 1926–27 was £1,691,000. From April 1, 1927, railway revenue was separated from the ordinary budget. For the year ended March 31, 1928, ordinary revenue was £1,904,000 and railway revenue (which showed a surplus over expenditure of £51,000) was £631,000 (E. Hea ; F. R C.)

HISTORY

The years immediately preceding the outbreak of the World War had been a period of much administrative and commercial activity in German East Africa There was a flourishing European settlement in the Usambara highlands and, as far as civil administration was concerned, the colony was self-supporting.

Post-war Administration.—The British and Belgians established their own administrations in the districts they conquered. It was not until March 22, 1921, that all the districts which Belgium had occupied but which fell within the British mandated area were transferred to Tanganyika Territory, the name officially given to the British area in Jan. 1920 A civil administration had been set up while the war was in progress, Mr. (afterwards Sir) Horace Byatt being the first administrator—a title changed in Aug 1920 to that of governor. The country had suffered severely from the ravages of war and the work of reconstruction was difficult and prolonged All the German settlers were repatriated and their estates sold Until this process was nearing completion few new land grants were made and agriculture for a time was practically at a standstill. Moreover, both the planters and the commercial community complained, with some show of reason, that the Government was indifferent to their needs Complaint was also made by the Europeans of the competition of the Indians. As to that the administration was tied by the terms of the mandate (which were approved by the Council of the League on July 20, 1922). The mandate enjoined equality of treatment to nationals of all members of the League in matters of "residence, trade and commerce." The administration was hampered by lack of funds and the necessity of rebuilding a large part of the central railway (the Dar-es-Salaam-Tanganyika line); and it had as its first duty the care of the natives, many of whom were restive and demoralized by the war. It had its hands full, nevertheless, it might have paid greater attention to the needs of planters—and the Amani institute for scientific research in all things connected with agriculture, which was one of the best works of the Germans, was allowed to go nearly to ruin

In Nov. 1924 Sir Horace Byatt was transferred to Trinidad and Sir Donald Cameron succeeded him as governor of Tanganyika. Meanwhile attention had been called to the suitability of the highlands in the southwestern parts of the territory for white settlement and a number of Europeans, mostly British, obtained farms there, on long leasehold, the administration having decided against freehold sales.

Economic Development.—By the middle of 1925 the era of transition after the war may be said to have ended. In June of that year ex-enemies were allowed to re-enter the territory (a step which would in any case have been necessary when Germany entered the League of Nations in Sept. 1926). Over 200 Germans, mostly former settlers, came to Tanganyika in the next 12 months, somewhat to the alarm of the British settlers. In a couple of years it was realized, however, that the German "invasion" was of limited extent, and a degree of co-operation was established between the British and Germans. The development of the country led in 1926 to the setting up of a nominated legislative council and occasion was taken of its first meeting (Dec. 1926) for a message to be sent by the king, who expressed his "deep interest in all that concerns the welfare of the people of Tanganyika Territory." This was more than a formality, it was intended to indicate the permanent character of the ties linking Tanganyika with the British empire. Agitation had been kept up in Germany for "the return of the colonies" and was directed as far as Britain was concerned to Tanganyika. Apart from the king's message explicit declarations were made by the British Government that the mandate gave Great Britain as secure control of Tanganyika as of territories actually British. The mandate simply imposed certain "servitudes," and even permitted the administrative union of Tanganyika—if that were thought desirable—with the neighbouring British territories. (*See* British East Africa) But economics as much as, or more than, politics engaged the attention of the administration and of the settlers. The Amani institute was reopened as a research department for the whole of East Africa; measures against the spread of the tsetse fly were taken; the rights of natives in the proprietorship of land were secured, much progress was made in education, for whites, Indians and natives alike, and particular attention was paid to improving means of transport A line from Tabora to Mwanza on Lake Victoria, opened in July 1928, was the first addition of any considerable length to the railway system since the war

TANGERINE (*Citrus nobilis* var. *deliciosa*), a small, thin-skinned variety of orange belonging to the Mandarin group, frequently called the "kid-glove orange," because of its loosely adhering skin, which may be removed without soiling the fingers It has a very sweet, spicy flavour, a delicate perfume, dry pulp and a large amount of oil in the skin. It originated in south-eastern Asia The tangerine is more quickly perishable than the orange (*q.v.*).

TANGERMÜNDE, a town in the Prussian province of Saxony, on the Elbe, 43 m N E. from Magdeburg by rail *via* Stendal. Pop. (1925) 13,123. It contains iron foundries, shipbuilding yards, refineries, and other industrial establishments, and enjoys a considerable river trade in grain and leather It has numerous brick buildings of the 14th and 15th centuries. The castle, built in the 14th century, was the residence of the margraves of Brandenburg.

TANGIER (locally Tanja), a seaport of Morocco, on the Strait of Gibraltar, about 14 m. E of Cape Spartel, nestles between two eminences at the north-west extremity of a spacious bay. The town presents a picturesque appearance from the sea, rising gradually in the form of an amphitheatre, with the citadel, the remainder of the English mole and York Castle to the right; in the central valley is the commercial quarter, while to the left along the beach runs the track to Tetuan. Several new roads have been made outside the town. In some of the older streets European shops have replaced the picturesque native cupboards; drinking dens have sprung up at many of the corners, while telephones and electric light have been introduced by private companies, and European machinery is used in many of the corn-mills, etc. The main thoroughfare leads from Báb el Marsa (Gate of the Port) to the Báb el Suk (Gate of the Market-place)

known to the English as Catherine Gate.

New European quarters have been built to the north of Tangier (the Marchan quarter) and to the south (quarter of the beach and of Suani). The harbour, formed by the Bay of Tangier, is good in all weathers except during a strong east wind, but vessels of any size have to anchor a mile or so out. The work of building a deep-water harbour was begun in 1925 and will take five years. The harbour will include several basins with a depth of 7½ metres, protected on the north and north-west by a breakwater.

The population of Tangier is 56,000, of which 33,000 are Muslim, 12,000 Jews and 11,000 Europeans (9,000 Spanish, 1,500 French). The trade of Tangier has risen to 175 millions (imports 146 millions, exports 29 millions). The share of France is 87 millions, that of Spain 30 millions, that of Great Britain 20 millions. Tangier, which was formerly the first port of Morocco, has suffered a great deal during the last 20 years from the jealousies of the European Powers, which has retarded its development. Casablanca and the other ports in the French zone have taken its place. The opening of the Franco-Spanish railway from Tangier to Fez, which took place in 1928, will doubtless enable the port to draw, from its magnificent geographical situation, the advantages it has the right to expect.

The Roman Tingis, which stood in the immediate vicinity of the site of Tangier, was of great antiquity; under Augustus it became a free city, and when Otho placed the western half of Mauretania under a procurator, he called it Mauretania Tingitana, after its capital, Tingis. It was held by Vandals, Byzantines and Arabs, and when Mulai Idris passed from Tlemçen to Fez in 788, Tangier was "the oldest and most beautiful city" of the Maghrib. After many futile attempts the Portuguese obtained possession of it in 1471, but it passed to Spain in 1580, returning again to the Portuguese in 1656. In 1662, as part of the dowry of Catherine of Braganza on her marriage to Charles II., it came into the possession of the English, and they defended it against Mulai Ismail in 1680, but in 1684 it was decided, on account of expense, to abandon the place to the Moors. It was bombarded in 1844 by the French, then at war with Morocco. In the early years of the 20th century the sharīf Raisūli terrorized the district round Tangier and made captive several Europeans. As one result of the Algeçiras conference of 1906 a regular police force was organized, and the control of the customs passed into European hands.

The Franco-German treaty after the crisis of 1911 and the Franco-Spanish convention of 1912 provided a special regime for Tangier and for a zone of 15–18 km. around the town.

(A. Be.)

1912–1928

The declaration of a French protectorate over Morocco did not alter the situation at Tangier, which was understood to fall outside the effect of that declaration. The jealousies of the Powers and of their local representatives, the obstruction with which certain Governments never ceased to meet every proposition of progress, prevented Tangier from benefiting from its superb position and becoming a place of commercial and maritime importance. So loud grew the complaints of its population that the Governments of Great Britain, France and Spain decided in 1913 to draw up a convention and introduce the special regime which the treaties accorded.

After months of negotiation the representatives of the three Powers concerned were on the point of signing the convention in 1914, when the World War broke out, and the Spanish Government refused to sign. No doubt Spain preferred to await the results of the War before she definitely signed away her hope of one day possessing Tangier herself.

Tangier, like the rest of Morocco, was little affected by the War. During that whole period there was but one incident of importance, the expulsion of the German and Austrian chargés d'affaires and the personnel of their legations. The internationalisation of Tangier rendered it doubtful what steps the Allied Governments would take on this question, but the sultan of Morocco, under whose direct jurisdiction Tangier lay, was himself an Ally and the Governments interested did not hesitate to act. At the conclusion of the War Europe was too occupied to give thought to Tangier, and the policy of obstruction continued, to the lasting detriment of the place. Peace was seldom disturbed, though the fighting in the neighbouring Spanish zone impeded trade and closed the roads.

The Statute of 1923.—It was not until 1923 that the question of Tangier's future was once more taken into active consideration. The situation had now changed. France's position had become stronger since the sultan had recognized her protectorate. The British Government was, however, still determined that an international form of government must be adopted, and Spain, having failed to benefit by the War, supported this demand. A preliminary conference in London in July 1923 failed to bring about any settlement. It served, however, as a useful exchange of views, and in the following October British and Spanish delegates proceeded to Paris where the negotiations were continued. On Dec. 18, 1923, the convention was signed by the representatives of France and Great Britain, and on Feb. 7, 1924, by Spain.

The new status of Tangier is based upon a charter of permanent neutral internationalisation, under the sovereignty of the sultan of Morocco, who maintains his control over Moslem and Jewish Moroccan subjects. The sultan is represented by a high Moorish official, the mendoub. The administration of this town and its zone rests in the hands of an administrator and two assistant administrators, who carry out the decisions of the legislative assembly, subject to their ratification by the committee of control. The convention laid down that during the first six years the chief administrator should be a French subject and his assistants a British and a Spanish subject. After that period they should be chosen by the assembly. A French and a Spanish engineer superintend the public works. The committee of control, consisting of the consuls of all the Powers—except ex-enemy Powers—who signed the Algeciras Act has power, by majority decision, to veto the acts of the legislative assembly. The legislative assembly consists of 26 members, chosen from the subjects of the Powers represented in Tangier and from the Moorish and Jewish population. The number of members representing each nationality is regulated by the local importance in population, trade and influence of the nationality in question. Clauses have been introduced into the convention and in the legal codes for progressive modifications at specified periods of time should modification be deemed necessary or advisable.

Regulations were made for the formation of a force of gendarmerie but not put into practice. The special legal codes are, however, in force and justice is administered in mixed courts by judges of different nationalities. The Muslim and Jewish subjects of the sultan have their own tribunals. The status was officially introduced in June 1925 and has made very tolerable progress. Its application was rendered difficult by the fact that neither the Italian nor the American Governments had accepted its conditions, and that the subjects of those two Powers were therefore not amenable to its laws or ordinances. During the summer and autumn of 1927 the French and Spanish Governments were in negotiation for certain changes in the status, following a demand from Spain for a more prominent part in the local government.

Conference of 1928.—In 1928, the French and Spanish Governments having arrived at a compromise on the subject of the redistribution of their respective representation in the International Administration of Tangier, and Italy having meanwhile consented to recognize the convention of 1923 on certain conditions, a conference of the four Governments concerned was held at Paris. After many meetings, the conference issued "The final protocol of the conference for the Amendment of the Tangier Statute"—a name far too optimistic, as its finality was more than doubtful. With the exception of the welcome participation of Italy in Tangier's International Administration on an equality with England, the results of the conference were few and unimportant. The Belgian command of the gendarmerie, a body which had never been created, was abandoned and the appointment of a Spanish commandant, with French and Spanish subalterns, was agreed upon. In return, the Belgians were granted a judgeship

in the mixed court. A "Bureau of Public Security" was introduced under a Spanish officer assisted by Spanish and French lieutenants. Their duty was "to watch over the security of Tangier and its zone." The Italians were granted the same representation as England.

These small changes in the régime were of no real importance and appear to have been accepted as a sort of compromise, no solution having been found to the more important aspects of the question—Tangier's financial burdens, or its relations with the neighbouring Spanish zone. The reorganization of the mixed court and the revision of the code, which were also advised by the conference, would have come about in the ordinary course of affairs, and were certainly advisable.

Tangier continued in a state of stagnation. Its trade showed no increase; and, except for a little more cleanliness in its streets, few changes took place. The construction of the port continued, and the railway to Rabat and Fez was opened, but there was very little amelioration to report in the situation.

Bibliography.—Tangier Convention (Cmd. 2096, 2203); A. Cases, *Tánger, dignidad nacional* (1922); P. Champion, *Tanger, Fès et Meknès* (1924). (W. B. H.)

TANGO, a slow, graceful dance in $\frac{2}{4}$ time. It probably originated with the African negroes; in 1911 it became popular in a modified form in America and subsequently in Europe. It has much in common with the Cuban *Habanera.*

TANG SHAO-YI (1858–), Chinese statesman, a native of Kwantung, the first foreign-trained Chinese to rise to high office, was one of the leaders of the Chinese nationalist movement. He was educated at Columbia University, New York, and in 1898 became consul-general in Seoul in succession to Yuan Shih-kai. He organized the Tibet Convention of 1906. He was appointed special envoy to Europe and the United States (1908). He played an important part in the negotiations that followed the revolution of 1911, and in 1912, became Premier under Yuan Shih-kai. In 1919 he was one of the four directors of the Canton Government and was minister of finance at Canton 1919–22.

TANISTRY, a custom among various Celtic tribes, by which the king or chief of the clan was chosen from among the heads of the septs and elected by them in full assembly. He held office for life and was required by custom to be of full age, in possession of all his faculties and without any remarkable blemish of mind or body. At the same time, and subject to the same conditions, a *tanist* or next heir to the chieftaincy was elected, who if the king died or became disqualified, at once became king. Usually the king's son became tanist, but not because the system of primogeniture was in any way recognized; indeed, the only principle adopted was that the dignity of chieftainship should descend to the eldest and most worthy of the same blood. Tanistry was abolished by a legal decision in the reign of James I. and the English land system substituted. *See* Brehon Laws

TANJORE, a city and district of British India in the Madras presidency. The city is situated on the right bank of the river Cauvery, and is an important junction on the South Indian railway, 218 m. S. of Madras. Pop. (1921) 59,913. As the last capital of the ancient Hindu dynasty of the Cholas, and in all ages one of the chief political, literary and religious centres of the south, the city is full of interesting associations. It was the scene of the earliest labours of Protestant missionaries in India. The modern history of Tanjore begins with its conquest by the Mahrattas in 1674. The British first came into contact with Tanjore by their expedition in 1749 with a view to the restoration of a deposed raja. In this they failed, and a subsequent expedition was bought off. The Mahrattas practically held Tanjore until 1799, when the district was ceded to the East India Company. The raja retained only the capital and a small tract of country round. He died in 1833 and was succeeded by his son Sivaji, on whose death in 1855 without an heir the house became extinct. Among buildings may be mentioned the palace within the fort, and the great temple of the 11th century, enclosed in two courts, surmounted by a lofty tower and including the exquisitely decorated shrine of Subrahmanya. The city is famous for its silk brocade, jewelry, carpets, inlaid copper-work, modelling in pith, etc.

The District of Tanjore has an area of 3,727 sq.m. It is irrigated by an elaborate system of dams, cuts and canals and the soil is exceedingly productive. The delta of the Cauvery occupies the flat northern part, which is highly cultivated, dotted over with groves of coco-nut trees, and densely populated. The staple crop is rice, grown on some five-sevenths of the cultivated area, and rice-milling has developed recently. Soap and mats are made and fishing carried on. The district is traversed by the main line and several branches of the South Indian railway. The chief seaport is Negapatam. The population in 1921 was 2,326,265

See *Tanjore District Gazetteer* (Madras, 1906).

TANKARD, a type of drinking vessel. The word was formerly used loosely of many sizes, usually large, of vessels for holding liquids; thus it was applied to such as held two or more gallons and were used to carry water from the conduits in London in the 16th and early 17th centuries. The word is now generally applied to a plain, flat-bottomed drinking vessel of silver, pewter or other metal, or of glass or pottery mounted on metal, with a hinged cover and handle, holding from a pint to a quart of liquor. (*See* Drinking Vessels.) The derivation is obscure. It appears in O.Fr. as *tanquart.* It may have been metathesized from Gr. *κάνθαρος*, Lat. *cantharus*, a large vessel or pot.

TANKS. The name tank was given during the World War to the bullet-proof, armed vehicle, driven by mechanical power and capable of crossing rough country and obstacles by the use of caterpillar tracks. The name was first used in Dec. 1915 as a blind to conceal the true nature of the experimental fighting machine then being secretly constructed in England; after the first appearance of the machine in the field the name was retained. To the British is due the credit of first conceiving and introducing this weapon which was destined to exert a decisive influence on the course of the War.

The Tank Idea in History.—From the earliest times men have attempted to find methods whereby they might move under some form of protection while they delivered blows at the enemy. Vehicles of many different types have been constructed throughout the ages with a view to solving these first principles of war and those vehicles were the forerunners of the tank. The earliest fighting vehicles of which there is a record, date back to 1200 B.C.

The development of firearms led to the virtual disuse of the fighting vehicle. The weight of armour which was necessary to provide protection was such that no armoured vehicle could be propelled across country by man-power or horse-power The necessity for a fighting vehicle still existed and was in fact accentuated, especially with the introduction of the machine-gun, there was, however, at the time no apparent solution to the mechanical construction of such a vehicle. As time progressed two inventions were developed and it was the combination of these that led to the construction of the tank. The two inventions were the caterpillar track and the high-speed internal-combustion engine. The former enabled heavy vehicles to cross soft ground by the use of a track or endless belt so that the weight was distributed over a large area of ground; the latter provided a light compact power unit by means of which the vehicle could be propelled. The combination produced tractors such as the Holt, invented and in common use in America before the War. Between 1907 and 1914 several inventors suggested that tractors of this nature should be constructed and provided with armour for use as a fighting vehicle in war. No official action was, however, taken in this direction. The prevailing military opinion among all nations prior to 1914 was that any future war would be mainly a war of movement, and although it was realized that a frontal attack against a defensive position would be costly, it was considered that such an attack would be greatly assisted or even avoided entirely by envelopment or flank action.

The opening phases of the World War appeared to confirm these views, but in September the Germans fell back and took up a defensive position on the Aisne and it was then that the great strength of modern field defences became apparent. The main source of strength of these defences lay in the machine-gun protected by an extensive use of barbed wire entanglements, and

MODERN TYPES OF MILITARY TANKS

1. "Mark V." Star tank illustrating its climbing capabilities. This type tank was developed by the British army soon after the battle of Cambral during the World War
2. Light standard tank of the T 1. type with machine gun mounted in the turret (U. S. Army)
3. Late model of fast, light tank known as the Christie wheeled caterpillar. Capable of unusual speed and easy to manoeuver
4. Heavy armoured (U. S. Army) tank in act of climbing out of a trench
5. Small, light type (Carden Loyd) of wheel-cum-track tank—or "armoured machine gun carrier" as used in the British army. This is capable of about 30 m.p.h on its wheels and 15 m.p.h. on its tracks. More recent models attain over 40 m.p.h. on tracks

they proved to be impregnable to attack by troops, equipped as they were in 1914, without the most prodigal loss of life. The efforts of the French and British troops early in October to outflank the Germans in the north, led to an extension of these defences right up to the sea. The Allies were then faced with a continuous defensive position without flanks that could be turned and they possessed no means of penetrating such defences. One solution of the difficulty appeared to be a large increase in the available artillery resources, particularly in the larger pieces and the provision of high-explosive shells. This solution was acted on at once and although no result could of course be expected for many months, it was hoped that sufficient artillery and ammunition would eventually be available to blast a way through the enemy defences and so re-establish the power of mobility.

Col. Swinton's Proposal.—Early in Oct. 1914 an officer of the Royal Engineers, Lt.-Col. (later Maj.-Gen.) E. D. Swinton, Royal Engineers, formed the opinion that a frontal assault against prepared positions, especially with limited artillery support, had become impossible, and that some form of power-driven protected machine which could traverse trenches and barbed wire was necessary to enable the attack to overcome the power of the defence. On Oct. 20, 1914, Col. Swinton saw Col. (later Sir Maurice) Hankey, secretary of the Committee of Imperial Defence, and put forward his scheme which was briefly to develop the Holt tractor and produce a mobile armoured machine which should lead the assault and act as a machine-gun destroyer.

As a result of the interview described Col. Swinton took up the question with G.H.Q. in France and Col. Hankey put the idea before Lord Kitchener; but in neither case did it lead to any result. Col. Hankey however also submitted the scheme to the prime minister as head of the Committee of Imperial Defence, and this reached Winston Churchill who was already experimenting with armoured cars for the naval detachment of the Belgian coast. On Jan. 5, 1915, Churchill wrote to the prime minister emphasizing the importance of Col. Swinton's suggestion. This letter was sent to Lord Kitchener, and at the same time Col. Swinton called at the War Office to discuss his proposals. As a result the matter received some attention and a few trials were carried out, after which the whole question was dropped. In the meantime Churchill formed a committee at the Admiralty under the chairmanship of Sir Tennyson d'Eyncourt, to investigate the problem. They carried out trials with large wheeled machines, coupled steamrollers, pedrail and caterpillar tractors, single and articulated, the underlying idea being the production of a machine for the conveyance of troops and not a machine-gun destroyer.

In the meantime Col. Swinton took his proposals to the commander-in-chief in France with the result that the specification of the type of machine required was sent to the War Office. By that time a joint naval and military committee had been formed and they were now able to work to a specification which detailed the military requirements. The result was the production—first of "Little Willie" which just failed to reach the standard required, and later of "Big Willie" or "Mother" as it was christened, which passed all tests at Hatfield on Feb. 2, 1916. The chief point in the design, and in which it differed from other caterpillar machines, was its rhomboidal shape and all round track which were the invention of Lt. (later Lt.-Col.) W. G. Wilson, working in conjunction with Sir W. Tritton. This machine, afterwards known as the Mark I. tank, was the prototype of all British machines used during the World War.

In the meantime normal trench warfare had been proceeding in France. The artillery had been considerably strengthened, but even then it was found at the battle of Loos that large numbers of enemy machine-guns would survive the heaviest bombardment and cause prohibitive casualties to the attacking infantry. G.H.Q. France therefore ordered 40 of these experimental tanks, and this number was increased by the War Office to 100 machines. A tank supply committee was formed under the Ministry of Munitions with Major (later Sir) Albert Stern as chairman. Orders were placed on Feb. 12 and production started at once with the utmost secrecy, and under great difficulties of labour and material owing to the great national effort to produce munitions of every kind.

The First British Tanks.—The Mark I. tank was built in two types, "male" and "female"; both types had "sponsons" mounted on the sides to carry the main armament. On the male tank this consisted of two 6-pdr. guns and on the female tank of four Vickers machine-guns. The idea was that the tanks would work in pairs, the male tank being more capable of dealing with defences behind brick walls or steel loophole plates and the female tank having greater man-killing fire power. The total number under construction was 150, half being males and half females. The Mark I. tank was 26 ft. long, weighed 28 tons and carried a crew of eight men. The maximum speed on the level was 4 m.p.h. and the tank could cross a trench 10 ft. wide. Reference has already been made to the track which was carried all round the tank; this track was driven from the engine through a two-speed gear box (controlled by the driver) and then through a differential which carried a second gear box at each outer end of the half shafts. These secondary gears were operated by hand levers and necessitated a gearsman on each side of the tank in addition to the driver. From these the drive was carried by chain to the driving sprockets in rear. As the original idea of the inventors had been that the tank should be used as a surprise on a large front the armour was for the most part only proof against ordinary rifle ammunition. It was realized that it might be necessary, as was indeed the case, to increase the thickness of the armour, in later models, to withstand armour-piercing bullets, when the enemy had had time to produce large quantities of these bullets. The male tank carried 324 rounds of 6-pdr. shell and 6,272 rounds of S.A.A. The female tank carried 31,232 rounds of S.A.A. Both types carried sufficient petrol for about 15 m. on a cross-country course.

A feature of this tank was the tail which consisted of a pair of steel wheels hinged on to the back of the machine and pressed down on to the ground with powerful springs. The wheels could be steered from the driver's seat and in this way the tank could negotiate easy bends; the wheels improved the balance of the machine and also slightly increased the trench crossing capacity.

In March 1916 a unit was formed to man these first tanks. For the purpose of secrecy the unit formed part of the Machine Gun Corps and was known as the Heavy Section, Machine Gun Corps. The name was later changed to Heavy Branch, Machine Gun Corps. The unit was commanded by Col. Swinton and contained sufficient personnel to man the 150 tanks under construction. The unit was organized in six companies of 25 tanks each. As soon as the tanks began to arrive from the contractors the unit encamped at a secret area near Elvedon in Suffolk and started driving and gunnery practice.

First Engagements on the Somme.—In the meantime the Somme (*q.v.*) offensive in France had come to a standstill. The right wing of the attack between the Somme and the Ancre which had met with some success at the start was definitely held up. The very heavy bombardments of the greatly increased artillery force had enabled the attackers to make some headway, but in the end the artillery fire had shelled away the barbed wire and replaced it by a worse obstacle, namely shell torn ground over which the infantry could only advance with difficulty, especially in wet weather. Moreover, this ground was quite impassable to transport. It was at this stage that it was decided to use the first two companies of tanks in an attempt to resuscitate the advance between the Somme and the Ancre. These two companies were accordingly sent to France at the end of August.

On Sept. 15, 1916, the first tank attack took place. The IV. Army was to attack and advance on the line Morval, Les Boeufs, Guendecourt and Flers and the V. Army on the left of the IV. Army was to advance on Martinpuich and Courcelette. A total of 49 tanks were to be used, the majority with the IV. Army. They were to advance in small detachments of two or three machines against the enemy strong points. The general idea was that they should advance so as to reach the objectives just before the infantry. In some cases lanes were left in the artillery barrage up which the tanks were to advance ahead of the in-

fantry. The tanks advanced at dawn in a slight mist and came as a complete surprise to the enemy; the results were, however, disappointing The tanks had been constructed to traverse wide trenches, banks and barbed wire obstacles, but not the shell torn ground which was the result of prolonged bombardment on a small area. Of the 49 tanks which were employed, 32 reached the front line. Of these nine went ahead of the infantry and rendered valuable assistance; nine kept up or followed just behind and helped in reducing strong points where the enemy were still holding out The remaining 14 broke down or sank and became ditched in the soft shell torn ground shortly after the battle had commenced. One tank in front of Flers gave remarkable assistance to the infantry and caused the surrender of 300 Germans. On Sept. 25 and 26, 13 tanks were employed on the same front and a few were employed later, on Nov 13. In each case a large proportion of the tanks were unable to negotiate the shell torn ground, but those that did rendered valuable assistance to the infantry, causing heavy casualties and the surrender of a large number of Germans.

The employment of the tanks in Sept 1916 was contrary to the views of those who had originated the arm and were responsible for its production. They considered that the tanks should be kept as a secret and used in large numbers as a surprise on a new portion of the front so as to give a chance of achieving decisive success It did however prove that the tank was a definite reply to the machine-gun and barbed wire and that infantry accompanied by tanks could attack defended positions with every prospect of success.

Improved Types.—As a result of these trials it was decided that the arm should be expanded to a force of 1,000 tanks. The tanks were not to be used again until the spring and the winter was to be spent in re-arming and training The original six companies were expanded to nine battalions and the force in France was to become three brigades, of three battalions each, under the command of Lt -Col (afterwards Major-Gen.) H. J. Elles, R E. Each battalion was organized in three companies and one mobile workshop, and each company was composed of four sections of four tanks each.

Although France had asked for 1,000 tanks, the design of the tanks had not been settled There was much discussion as to whether a completely new design should not be introduced; suggestions were made that a type with much wider tracks, or possibly equipped with more than one pair of tracks, should be tried In the meantime 100 machines were ordered which were to be similar to the Mark I. machine, but with certain minor improvements These were known as the Mark II and Mark III. machines. Other than the obvious fact that tanks had difficulty in crossing the pulverized ground on the Somme which was covered with craters and shell holes, the only military lesson that had been learnt as regards tank construction was the fact that it was not worth while fitting the tail to the tank; owing to its vulnerability and complications, it was constantly out of action and was of little value The Mark II and III. machines were therefore both very similar to the Mark I, the main differences being the provision of stronger rollers, and stronger armour to withstand the armour-piercing bullets which the Germans would be fairly certain to use in the next battle.

In the meantime the authorities in England who were responsible for the production of tanks were becoming perturbed about the delay over a decision as to the design of tanks for the order of 1,000 machines For the original idea of fighting a surprise battle on a new front the existing design was suitable, but to produce the ideal machine for traversing the shell torn ground of an old battlefield, a new and special design was necessary and this would mean a complete new series of experimental trials involving much delay. It was not till the end of March, involving the loss of five valuable months, that a decision was reached and it was then decided that the 1,000 machines should be of a type known as the Mark IV This type was again very similar to the Mark I., using the same engine and transmission and the same shape of hull. It included the minor improvements already incorporated in Marks II. and III. and in addition had sponsons which could swing into the body for travelling on a railway, and so saved the labour of detaching and remounting these heavy sponsons for every railway journey. Another feature of this tank was that it carried an unditching beam which could be fastened when required on to the tracks to extricate the tank from a ditch. The Mark IV. tank was the main machine used throughout 1917 and the early part of 1918.

The next action in which the tanks took part was the battle of Arras (*q v.*) on April 9 in which the I., III. and V. Armies attacked with a view to penetrating the German defences and allowing an Army Corps and two cavalry divisions to break through. Only 60 tanks were available for this attack and they were again used in the minor rôle of assisting the infantry to "mop up" machine-gun nests and small posts that had been passed over by the artillery barrage and the assault of our leading troops. The tanks were of the Mark I, II. and III. pattern and some of them suffered heavily from armour-piercing bullets. In many cases the tanks rendered valuable assistance, overcoming enemy machine-guns and barbed wire with ease. The cavalry were prevented from breaking through owing to the usual obstacles—barbed wire and machine-guns—the tanks being far too few in numbers and too dispersed to be able to keep up the pressure and assist in further operations.

Messines.—The next attack was against the Messines-Wytschaete ridge on June 7 in which 76 Mark IV. and 12 supply tanks were used The latter were made from old converted Mark I or II. tanks and were used to keep the fighting tanks supplied with petrol and ammunition—a need which had been much felt in former battles. The attack was in the nature of an assault in the old form of siege warfare. The result was a complete success in which the tanks only played a small part, though in a few individual cases they rendered valuable help The ground was completely pulverized by the preliminary bombardment but very few tanks became ditched, mainly owing to the fact that there had been no rain for many weeks and that there had been time to make a close reconnaissance of the ground and pick out the best lines of advance for the tanks. After this attack the arm was renamed as the Tank Corps

On July 31 the battle of Ypres (*q v*) was launched As the preliminary bombardment had been so successful at Messines it was decided again to use a long preliminary bombardment lasting ten days. The danger of thus rendering the ground impassable to tanks, especially if it rained, was explained by those responsible for the action of tanks, but it was considered that the value of the bombardment more than balanced the possible loss of the use of tanks, this did not prove to be the case as the Germans adopted a defence distributed in depth which did much to discount the value of the bombardment. Unfortunately it rained on the first day of the battle and although the tanks rendered much assistance in individual cases during the early stages of the attack, the ground soon became quite impassable to tanks, and later it became impassable to infantry as well.

Success at Cambrai.—Although the failure of the tanks at the third battle of Ypres was through no fault of the officers and men and those who commanded them, it lead to much discussion as to whether tanks should be retained at all. The Germans formed the opinion that the tank was practically useless, and many British officers held the same view. Fortunately this view was not unanimous and on Nov. 20 permission was obtained to launch an attack at Cambrai, in which the tanks were to be used in the way in which their originators had intended that they should be used This was the turning point in the history of the Tank Corps. The action as fought was in almost every detail the execution of the plan put forward officially for the employment of the tanks by Col. Swinton in Feb. 1916, seven months before the first tank action. The attack was to be a complete surprise and no preliminary bombardment was to be used. Three brigades of tanks (nine battalions) were to take part with a total of 378 Mark IV. tanks and 98 administrative machines (*see* CAMBRAI).

The attack was launched at 6.20 A.M. in a slight fog, Maj.-Gen. Elles leading the attack in a vanguard tank with the centre division. The operation was a complete success; the enemy were

taken absolutely by surprise and most of the infantry bolted or surrendered. Within 12 hours the infantry had advanced 12,000 yd. on a front of 13,000 with only 4,000 casualties. A similar penetration at Ypres had taken three months, with enormous loss of life and morale. The preliminary bombardment which had cost some £22,000,000 at Ypres was dispensed with and a further advantage was gained in that the roads had not been torn up with shell fire and were available for use almost at once. And this had been achieved by the Tank Corps using great mechanical power, but numbering only 4,000 of all ranks.

As regards tank design three main lessons were learnt from the battle of Cambrai. First of all the tanks required to be handier, and controlled by one man, without the assistance of any gearsmen, and to meet this requirement the Mark V. tank was produced. This design had been suggested but not accepted almost a year previously. Outwardly the tank had the same appearance as Marks I. to IV., but the engine and transmission were much improved. The engine developed more power and the steering was effected by using epicyclic gears on the transmission to each track; this was the best tank produced during the War. Then the difficulty of crossing the wide trenches of the Hindenburg line had been considerable, and a certain number of special long tanks were ordered for this purpose. These were made from Mark V. tanks by adding a section in the centre to obtain the required length, and were known as Mark V.* tanks. Later an improved type was made with a more powerful engine known as the Mark V.** The third lesson was the necessity at times for a much more mobile tank for use beyond the main trench systems. These tanks would not need to cross wide trenches and hence they could be shorter and lighter and more mobile. One type, known as the whippet, had already been constructed experimentally. These lighter tanks became known as "medium" tanks, and the whippet was named the Medium Mark A.

German Offensive of March 1918.—The Tank Corps was now expanded to five brigades of 13 battalions with 320 Mark IV. machines and 50 Medium A. machines. During the winter of 1917–18 all units were training and being equipped with new tanks. No further offensive operations were in view and there ensued a period of preparation for the expected German attack in the spring of 1918. To assist in repelling such an attack the Tank Corps was distributed in detachments on a front of some 60 miles.

The attack was launched on March 21 (*see* St. Quentin, Battle of), and the Germans advanced rapidly. The tanks took part in many improvised attacks in attempting to stem the German advance. Some of these met with fair success and caused heavy casualties but the tanks were too few and too dispersed to make their real weight felt. It was during this retreat that the Medium A. tanks were first engaged in action and they met with considerable success, their additional mobility being of great assistance in this type of warfare. The attack fought itself to a standstill within a month, immobility being caused more by the difficulties of transport than by the resistance offered by the Allies. The supply of ammunition and food to the advanced German troops, especially where the lines of supply crossed the old battlefields, became exceedingly difficult, and it was at this stage that the necessity for some form of cross-country transport to enable an army to pursue across the devastated country left behind by the opposing force, began to be realized. The Tank Corps had already foreseen its own requirements by the provision of supply tanks and sledges drawn by tanks, and later by moving signalling equipment in special signal tanks.

In the meantime a reaction had set in as regards the estimated value of fighting tanks. The critics asserted that the battle of Cambrai could never be repeated and pointed to the lack of decisive results achieved by the tanks during the German advance. The proposed expansion of the Tank Corps was postponed and the existence of the corps seriously threatened. Fortunately the Mark V. tanks were now arriving at the rate of about 60 machines per week, and on July 4 one brigade of tanks equipped with these machines carried out a surprise attack on the Germans at Hamel in conjunction with the Australians. The attack was a complete success. The extra handiness and mobility of this machine enabled it to be used very effectively against machine-guns, many of which were crushed and rolled into the ground.

The Triumph of the Tank.—The great French victory of Soissons on July 18, 1918 (*see* Marne, Second Battle of the), marked the turning point of the War; the victory was largely due to the use of French tanks employed in much the same way as the British had used their tanks at Cambrai. This was followed by the opening of the British strategic offensive on Aug. 8 with the battle of Amiens (*q.v.*). In this attack the tank tactics were those of Cambrai modified by recent experience and adapted to the improved machines available. The attack was carried out by three army corps, a cavalry corps and 11 tank battalions; nine battalions were equipped with Mark V. tanks and the remainder with Medium A. tanks. For the first time since tanks had been used for an offensive it was possible to keep some in reserve and 42 tanks were kept in hand. The attack was a complete success, the greatest penetration of the tanks being 7½ miles. The tanks continued in action till Aug. 11.

From that date until the Armistice tanks took part in every main attack and in no case, where tanks were properly employed in conjunction with the other arms, did the attack fail. During this period the tanks co-operated in the battles of Bapaume, Epehy, Cambrai, St. Quentin, the Selle and Maubeuge. Tanks came to be looked upon as essential to the success of any attack, and in his final dispatch the commander-in-chief stated that the successful attacks which won great victories at Amiens and afterwards would have been impossible without tanks. The Germans also confessed that it was the tanks that had caused the downfall of their armies in the field. An expansion of the Tank Corps to 34 battalions had been sanctioned if the War continued into 1919, and the Ministry of Munitions in England had hoped to produce a total of 6,000 machines in 1919.

FRENCH AND AMERICAN TANKS

Independent Invention by the French.—The French were faced with the same difficulty as the British in the early stages of the War, and their attacks were held up by machine-guns and barbed wire although they were often well supported by artillery using high-explosive shells. It was Col. (later Gen.) J. B. E. Estienne of the artillery who first perceived the necessity for some mechanical machine which could cross the trenches and barbed wire in the face of machine-gun fire, and when this officer saw the Holt caterpillar tractors at work behind the British front for hauling guns, it occurred to him that the solution might be found in an armoured caterpillar machine. On Dec. 1, 1915, Col. Estienne put forward his idea officially to the French commander-in-chief and asked for an interview. Thus the ideas which had been thought out by the British originators in 1914 were re-invented separately and independently by the French in 1915. As the result of Col. Estienne's interview, 400 tanks were asked for and the design was to be prepared jointly between Col. Estienne and M. Brille of the Schneider Works. Later a further order for another 400 machines was placed with the St. Chamond Works.

In June 1916 French Headquarters received information from British G.H.Q. as to what was being done in England. Col. Estienne visited England and saw the Mark I. tanks in training. He expressed the view that the two countries should collaborate as regards the production of tanks and that as the British had progressed with the design of a large heavy machine, the French might specialize with a light machine for more mobile warfare. Col. Estienne was specially insistent in the view that neither country should forestall the other in the use of tanks, but that they should co-operate and launch a great offensive in which both British and French tanks might obtain full value from surprise.

French Light and Medium Tanks.—The first light tank was produced by the Renault firm in November but the production of these small machines did not receive official support. The French classified their tanks or "chars d'assaut," as they were

called, in three categories, and this classification was generally accepted. The light tanks were under 10 tons in weight and were to be transported over long distances in lorries. The medium tanks (St Chamond and Schneider) weighed between 10 and 30 tons and could be transported by rail on ordinary trucks. The heavy tanks, of which the British Mark I. formed the only example at the time, were machines weighing over 30 tons and required special railway trucks for transport.

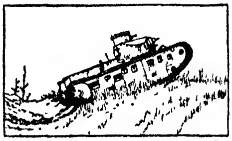
A training centre was now formed at Marly-le-Roi and later an additional centre was started at Champlieu. On Sept. 30, the artillerie d'assaut, which was the counterpart to the British Tank Corps, was formed under the command of Col. Estienne. The French medium tanks now began to arrive. The Schneider tank was six metres in length and driven by a 60 h.p. engine It was armed with a short 75 mm. gun and two machine-guns. The St. Chamond tank was somewhat larger and heavier, being 8 metres in length and driven by an 80 h.p. engine through a petrol-electric transmission. The armament was one 75 mm. gun and four machine-guns. Both machines differed radically from the British tank in that the track was not carried round the machine but consisted of the ordinary short type used on tractors. This resulted in the machines having very limited climbing power out of shell holes or craters. The artillerie d'assaut was organized in "groupes"; each "groupe" had four batteries of four tanks each. The light Renault tank was used as a "command" tank and one was allotted to each "groupe."

The delivery of both types of tank was very slow and instead of 800 tanks being ready for the spring offensive in 1917 only 250 had been received. The result was that only 10 "groupes" were able to take part in Gen. Nivelle's offensive. The French high command had grave doubts whether to make use of so small a number of tanks, but eventually decided to do so. The offensive was unsuccessful and although the tanks did good work in isolated cases, the result was disappointing. The employment of tanks in this manner was a repetition of the mistakes made by the British.

Success of the Renault Type.—Between this date and the end of the year 1917, the French tanks were again used on several occasions with similar results. On Oct 23, five "groupes" took part in the battle of La Malmaison and met with much success though the battle was not launched as a surprise and was preceded by an artillery bombardment. During this period much discussion took place and designs were prepared for improved medium tanks and for heavy tanks. Finally in Dec. 1917 it was decided to concentrate on the Renault light type; this was the machine that Col. Estienne had asked for in 1916. Some of these tanks were already on order but production had been very slow. In Jan. 1918 it was decided to increase the orders to a total of 4 000 light tanks, of which 1,000 were to be ready by the end of March. The Renault tank was a small machine weighing 6½ tons. The length was four metres and in addition there was a short skid tail in rear to assist in trench crossing. It was driven by a 35 h.p. engine. There were two types, one being armed with a 37 mm. gun and the other with one machine-gun. The crew consisted only of two men, one driver and one gunner.

The French had hoped to use their tanks in mass in a great offensive in the spring or summer of 1918, but the German advance on March 21 upset all these plans. Instead the tanks were used piecemeal and in local counter-attacks to stem the German advance. In May and June tanks were used on occasions and the Renault tank made its first appearance in battle on the east of the Forest of Retz During this time the artillerie d'assaut was reorganizing and rearming On July 18, the second battle of the Marne took place and the French tanks came into their own. It was in many ways a repetition of the battle of Cambrai, but as the warfare had been of a semi-mobile nature for some months, the wide trenches of static warfare were non-existent. This suited the Renault tanks. The attack was launched as a surprise using a total of 120 medium tanks and 700 Renault tanks. The attack was a complete success and definitely established the value of the tank in the French army. From that date until the Armistice, the French tanks—mainly Renault tanks—took part in practically every attack and contributed largely to the success of the final French offensive.

American Tanks.—The Americans were quick to grasp the great possibilities of tank action on the Western Front and this form of mechanical warfare appealed to their national characteristics. Officers were sent to study the employment of tanks and questions relating to their construction and design. As a result the Americans decided to adopt the British heavy type of tank and the French light type known as the Renault tank.



BY COURTESY OF THE ARMY ORDNANCE ASSOCIATION

U.S A. 1921 MEDIUM TANK (22½ TONS)

In Dec. 1917 an allied commission was formed and it was decided to construct a tank known as the Allied tank; this was a heavy tank similar to the latest British type and was to be the Mark VIII. tank for the British Army. It was designed to use the Liberty aero engine and was known in America as the Liberty tank. A factory was erected at Neuvy Pailleux which was eventually to be capable of constructing and assembling these tanks at the rate of 1,200 a month and the first 600 were to be used for equipping the first American tank units. A large constructional programme was also started in America to produce both this type and the French Renault tank. The first tanks of this type were not constructed until just after the end of the War, but several American tank units equipped with British and French tanks took part in the latter phases of the War and met with marked success. If the War had continued the American tanks would have come in with an overwhelming effect in 1919.

Anti-tank Defence.—The Germans never made an attempt to construct tanks in large numbers, partly owing to the restricted manufacturing power possessed by Germany compared with the Allies, and partly to the comparative failure of the British tanks at Ypres in 1917. A rather clumsy type of heavy tank known as the A.Y.V. was constructed in small numbers. These and a number of captured machines were formed into units and used in small numbers in a few isolated cases during 1918, but owing to the way in which they were employed and handled they met with little success.

On the other hand the Germans made continual attempts to introduce some form of anti-tank defence, but as the British tanks met with comparatively small success in the early stages, these measures were only developed half-heartedly. The first step was the introduction of armour-piercing bullets which was countered by the use of thicker armour on the Mark IV. tank. Next the Germans turned their attention to the employment of field guns specially allocated for anti-tank defence and often dug in or concealed in the forward areas. The employment of field guns in this way seriously depleted the power of the German artillery for other purposes, but they were meeting with considerable success until the introduction of the Mark V. tank, which, with its increasing mobility was able to reduce very largely the value of this field gun defence.

In addition the Germans often employed obstacles such as pits and barricades or mines. The former required a large amount of material and labour in construction, and could usually only be made in isolated places or in defiles, and did not seriously trouble the Allied tanks. The latter were a source of danger to friend and foe, and required much time and material before a continuous line of minefield could be constructed. Although tanks were blown up in isolated cases by German mines the danger was never serious. The Allies made preparations to meet enemy tank attacks with field gun fire and in some cases by the use of male tanks kept in hand for this purpose. The latter is the most certain method of secure defence against tanks but was never adopted by the Germans. In 1918 the Germans evolved a heavy anti-tank rifle which was capable of penetrating the armour plates of the tanks, but the rifle had a heavy recoil and was difficult to handle and did not prove successful as an anti-tank measure.

After the success of the Allies at the battles of Soissons and Amiens in July and Aug. 1918 the Germans were awakened to the great danger in which they stood from tank attacks. They then constructed a heavy machine-gun firing a 13 mm. bullet and capable of penetrating 30 mm. of armour. The gun was known as the Tuf, and great efforts were made to construct it rapidly and secretly, but none was ready till after the Armistice.

PROGRESS IN TANK DESIGN

With the exception of the Germans, who are prohibited by the Peace Treaty from doing so, all great nations now employ tanks as part of their military force. The French have retained the Renault tank as the main armament of their tank corps and although they have carried out much experimental work, no models have been considered sufficiently advanced to standardize and construct in any large numbers. The Americans have also constructed many experimental patterns, and after for long retaining the Mark VIII. or Allied tank as the heavy tank with which their tank units are equipped, are now superseding it by a 23 ton tank with a crew of four, a speed of 12 m.p.h., a protection of an inch of armour and an armament of one 6-pounder and two machine-guns. The Renault has also been replaced by a light tank with a speed of 18 m.p.h. and a cruising radius of 80 miles. It has a crew of two and an armament of one 37 mm. gun and one machine-gun.

The British, as the originators of the tank, have sought to maintain their lead. Some months before the conclusion of the World War, when preparations were being considered for a great offensive in 1919, the specification was drawn up for a tank which was to be a great advance on the existing patterns. It was to have a speed of 20 m.p.h. and be capable of floating and propelling itself across water. Enough petrol was to be carried to travel 200 m. cross country, and the tank was to be long enough to cross a trench 12 ft. wide. This tank was to be used for attacking the enemy communications and headquarters while the more conventional tanks were attacking the main armies in front. The first experimental model was actually completed just after the Armistice. The tank used a system of spring suspension on a cable and hydraulic power for control. Although the machine attained a speed of 28 m.p.h. and swam successfully across a narrow river on several occasions, it proved to be unreliable owing to the many new devices which it contained and which required further development. The problem of steering has been found to present many mechanical difficulties and, although much work has been done, no satisfactory solution has yet been found.

The Vickers Tank.—In the meantime the British Tank Corps which was reduced to four battalions after the War, was armed with the Mark V. tank and the Medium C. The Medium B. replaced the Medium A. at the end of the War, but very few of this model were made and the units were equipped with an improved type in the Medium C. This machine had a maximum speed of 12 m.p.h. and a radius of action of 70 m. and would have been a very useful tank in France. But by 1920–21 these machines were becoming worn out, and, although much knowledge had been gained, the experimental machines aiming at far higher achievements, and which have already been referred to, were not yet in a satisfactory state for production. A tank was therefore designed which was constructed on conventional lines and aimed at obtaining a high degree of mobility, if necessary at the expense of trench spanning capacity. The machine was known as the Vickers light tank. It is 18 ft. in length and weighs 10 tons and is armed with one 3-pdr. gun and two machine-guns. It can attain a speed of over 20 m.p.h. and travel 150 m. on the petrol that it carries.

One Man Tanks.—In 1925 a new line of development was started by the British and the first one man tank[1] was constructed. The essence of the idea was to produce a small cheap fighting machine which could be used in large numbers, either instead of or in addition to the much larger and more expensive fighting tanks. The anti-tank weapons have become a serious threat to the large tanks used in the small numbers that peace time financial stringency dictates, but if they can be split up into 20 times as many small tanks, the casualties can be reduced by the use of dispersion. Furthermore, small cheap tanks provide a means of sending out scouts and a protective screen which the tanks did not formerly possess. It was with these ideas in mind that the first of these small tanks was made. The original idea was that one man should both drive and fight the machine, and practical trials showed that this was not impossible. The advantage of having only one man was that for the same charge on army funds, a larger number of machines could be manned and maintained than if two men were used in each machine. After due consideration it was, however, decided that these small tanks should be made to take two men each, the one to drive and the other to fire the machine gun.

As a result of demonstrations given with the first experimental model, the firm of Morris Commercial Cars were asked to make a number of these small tanks which were later christened tankettes. The main idea was to endeavour to use commercial components as far as possible so as to reduce the cost and thus enable large numbers to be used. The first models had many defects but they served to launch the idea and to raise interest in this new development. A little later the firm of Carden Loyd Tractors came forward with proposals which they had had in mind for some time. Their original idea was a low unarmoured one man machine but this proved to be impracticable and they then developed an armoured two man tankette. Their early models had many mechanical defects but these were gradually overcome and later models were very successful. At the end of 1927 the term tankette was replaced by light tank and the Vickers tank was renamed as a medium tank. In their present form these light tanks weigh about 2 tons and cost about £500. They can travel 20 m.p.h. on good going, can cross most small ditches and natural obstacles, can move along tracks and pass between trees in some woods.

Mechanized Warfare.—From the moment that tanks arrived in France during the World War there arose a demand from other arms for assistance from vehicles of this nature with track transmission. Artillerymen required track vehicles for the forward transport of some of their guns, the administrative services required track vehicles to enable them to maintain supplies across shell stricken areas, and the whole subject was grouped rather loosely under the name of mechanical warfare. The various ways in which mechanically propelled vehicles can be used to assist an army can be divided, for the sake of clearness in discussion, into strategical, tactical and administrative mechanization.

Strategical mechanization is used to enable a commander to move troops over long distances with great rapidity, *e.g.*, if the necessary vehicles are available, a complete Division can be moved 100 m. in 24 hours, and if the vehicles are of a cross country type, the move may be carried out across country where the enemy has endeavoured to impede progress by the use of extensive demolitions.

Tactical mechanization is used to enable the men to fight on the move and behind armour on the battle field, *e.g.*, the tank, the armoured car, and the gun on a self-propelled mounting.

Administrative mechanization is used to assist the administrative services in several ways, *e.g.*, mechanized artillery need far less weight and bulk in petrol than a corresponding unit in forage, and this greatly aids administration by reducing the demands on shipping. Vehicles with a cross country capacity may enable the Staff to feed troops over an area in which ordinary lorries and horses would be quite unable to cope with the work.

Considerable progress has already been made with strategical mechanization. For a long time attempts were made to use track vehicles for this purpose, and considerable difficulties were encountered, but more recently the six-wheel lorry was invented, and the development of this vehicle has overcome nearly all the troubles. In the British army a start has already been made in mechanizing the first line transport of infantry battalions with these vehicles, and there is every chance of their commercial employment, which means that the army will be able to draw on civilian resources for mobilization. This would pave the way

[1]The idea was initiated and the first tank constructed as a private experiment by Major G. le Q. Martel, D.S.O., M.C., R.E.

for a considerable extension in mechanizing first line transport, and thus overcome the main objection to strategical mechanization, for although there has never been any great difficulty in collecting buses and lorries for the rapid transport of dismounted men, the movement of their first line transport has represented a serious difficulty in the past. By the use of six-wheel lorries, the first line transport can travel with the buses, and the whole unit can move considerable distances at high speed There are, of course, some forms of tactical mechanization which bring with them strategical mobility, but the necessity of carrying armour reduces this mobility in a large degree. Strategical mechanization offers very considerable advantages to the commander of a force. It renders no actual assistance to the infantryman in an attack on the battlefield, but it may enable a commander to move one or more infantry divisions with great rapidity to the flank or rear of the enemy position and so achieve his object without the use of any armoured fighting vehicles at all.

Administrative mechanization is closely wrapped up with the progress that is being made with strategical mechanization. The six-wheel lorry brings with it a great saving in financial expenditure in peace time, and in war it would enable a large reduction to be made in the tonnage which has to be transported by rail or sea to maintain a force, compared with the amount that would be required for a similar force using horse transport, because the necessary quantities of petrol and oil would be far smaller in both weight and bulk than the corresponding amounts in forage. In addition, a commander with an adequate number of six-wheel lorries at his disposal can face an advance through an area over which an enemy has retreated and demolished all communication, with the knowledge that he will be able to maintain his troops with the necessary supplies and munitions

It is concerning tactical mechanization, however, that there is so much difference of opinion and discussion. Here the six-wheeler is of little value. It is true that six-wheel armoured cars will be useful for long distance reconnaissance, but their fighting value may not be great Their mobility is entirely dependent on the pneumatic tyre, which is at present very vulnerable though recent developments may give it greater immunity. These tyres can be replaced by semi-solid tyres of various types which are unaffected by bullets, but this reduces the cross country capacity of the vehicle and the speed on roads to a considerable extent. The six-wheeler is therefore at present mainly limited to armoured reconnaissance and armoured mounts for officers and staff, and although these duties are important, they represent only a small part of the work of armoured fighting vehicles.

The present trend of thought is to divide the use of tactical mechanization into two branches—the employment of armoured fighting vehicles with normal formations such as an infantry division, and their employment in an independent mechanized force whose rôle would be to carry out turning movements and attack the enemy in flank or rear or to attack his communications.

Tanks are likely to be employed for many years to come in co-operation with infantry skirmishers in any carefully staged attack against a defensive position. The smaller tanks will in addition be used for scouting and reconnaissance work, while the larger tanks are kept for the decisive attack where trenches and obstacles may have to be surmounted which would be impassable to the lighter tanks. It is the employment of an independent mechanized force, however, that presents such difficulties and yet holds out great possibilities. This is in reality the modern form of independent cavalry, and just as the horseman was supreme on the battlefield in the early middle ages, so the advocates of an independent mechanized force consider that in this, their latest and most modern form, they will again reign supreme.

An Experimental Mechanized Force.—All the views that have been expressed have been based on theory, and as no one is going to re-organize an army on theory alone, the British army formed an experimental mechanized force. In this force the tanks and the necessary supplementary arms and weapons are being tested out, and facts will be gained which will supplement or replace theories. There are many lessons which can never be learnt except on the battlefield, but there are others, such as the fatigue of tank crews and the capabilities of the machines, which can be determined exactly, and in many ways the manoeuvres with this force will provide a valuable guide as to the capabilities of an independent force of this nature. In 1928 the American army also formed a mechanized force.

The British mechanized force was formed in July 1927, and consisted of one battalion of Vickers tanks (48 tanks), two companies of armoured cars, a company of 16 light tanks, one mechanized brigade of field artillery and one light battery, one machine-gun battalion carried in half-track vehicles, one mechanized company of Royal Engineers, and a specially equipped company of the Royal Corps of Signals. It was realized that there were too few light tanks and armoured cars. The vehicles with which this force was equipped were by no means ideal, but it was thought better to carry out tactical trials and gain some information in this way with vehicles that were available at the time, rather than await the development of more perfect machines. If the trials developed successfully, it was intended that the force should travel entirely in armoured vehicles so that the whole force should be proof against small arm fire

A series of trials were carried out on Salisbury plain. It may be argued that these rolling plains were unduly favourable for the mechanized force, and that much greater difficulties would have been encountered in almost any other part of England when the force moved across country This is true, but on the other hand the enclosed country which is so common in England is not found to any great extent elsewhere, and Salisbury plain is much more typical of Europe. In these trials the plan was evolved of using a light group ahead, consisting of armoured cars, light tanks and light guns, and following up with a heavy group of Vickers tanks and mechanized artillery. It was the duty of the light group to carry out long distance reconnaissance with armoured cars, and close reconnaissance with light tanks; they were responsible for gaining and keeping touch with the enemy and holding important points. The heavy group followed close up, and when the enemy main body had been located, they were used to strike a decisive blow. At the end of 1927 the name of the force was changed to the Experimental Armoured Force.

These trials are, however, in an elementary stage; as the equipment of the force improves, the anti-tank weapons of the opposing side will be developed. There are those who argue that the tanks will be developed with much heavier armour and a higher speed, and will be capable of resisting the smaller calibres of anti-tank weapons, and that development will be on naval lines up to huge battle tanks. There is, however, this fundamental difference between the army and navy, that whereas a battleship on the open sea is all powerful and can destroy in a few moments any inferior surface craft that appears within range, a battle tank would be in no such position. A single gun concealed in a wood may be within a few hundred yards of a big powerful tank and yet quite unseen, and it could destroy the tank before a shot could be fired in return. It is possible that development will be in the other direction, *i e*, towards smaller and more numerous tanks which can avoid casualties by dispersion.

The present attitude of nearly all armies towards tactical mechanization is to watch developments. It is possible that the progress in design of anti-tank weapons may render the supremacy of fighting vehicles short-lived On the other hand the development of these vehicles may surpass that of anti-tank weapons. Much will be learnt from the trials with the armoured force on Salisbury plain. The formation of this force was a most progressive step; just as the British were the first to conceive and use an armoured fighting vehicle—the tank—on the battlefield, so they have been the first to extend the idea to the use of a self-contained armoured force. The future progress will be watched with interest

TANNA: *see* GAON.

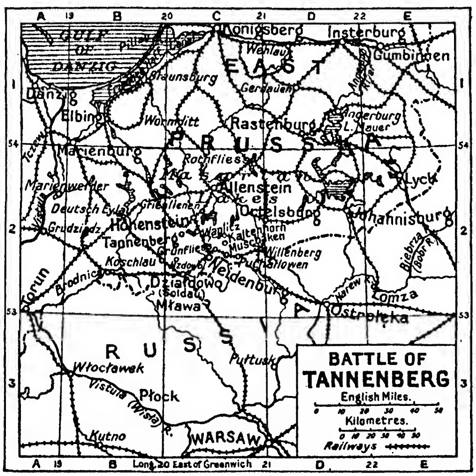
TANNAHILL, ROBERT (1774–1810), Scottish song-writer, son of a Paisley silk-weaver, was born on June 3, 1774. He was apprenticed to his father's trade at the age of 12, and, inspired by the poetry of Robert Burns, he wrote verses as he drove the shuttle to and fro. He began in 1805 to contribute verses to Glasgow and Paisley periodicals, and published an edition of his poems by subscription in 1807. Three years later, on May 17, 1810, he committed suicide. Tannahill wrote some charming songs. "Loudon's Bonnie Woods and Braes," "Jessie, the Flower o' Dunblane," and "Gloomy Winter's Noo Awa" are the best.

Tannahill's centenary was celebrated at Paisley in 1874. *See* edition by D. Semple (1876) for details of his life; also Brown's *Paisley Poets* (vol. i., 1889).

TANNENBERG, BATTLE OF. No portion of the earth's surface has been more fought over than East Prussia. It was in 1410, on the field of Tannenberg, that the Teutonic knights were utterly routed by their enemies the Poles and Lithuanians, and the German victory of 500 years later was in some degree the reversal of this defeat.

The Tannenberg of 1914 was the greatest victory achieved by any of the combatants at the commencement of the World War, and its strategic and moral effect upon the struggle were far-reaching. France and Russia had been joined by military convention since 1892 and their chiefs of staff had made careful arrangements for concerted action. In case of war with the Central Powers it had been agreed that Germany was the main enemy and that the principal military effort must be made against her.

Owing to the vastness of her territory and to the comparatively undeveloped state of her railways, Russia's rate of concentra-



tion was considerably slower than that of France, so much so that there was a danger of the latter being crushed before the attack on Germany in the East could begin to exert its effect. Unfortunately, under the pressure of French insistence, the good will and optimism of Russia's military leaders exceeded practical possibilities and the outbreak of war found her military plans in some disorder. All their initial operations in East Prussia were in fact hasty improvisations.

Geographically, East Prussia points forward into the heart of Slavdom and constituted a difficult problem of defence for Germany. True to her policy of concentration of force at the decisive point, she had decided to advance against France with her main forces whilst maintaining only a minimum of strength in the East. Not wishing to abandon national territory without a blow, she had decided to concentrate this minimum strength in East Prussia, despite the dangers involved in such action. Germany's strength in the East was to consist of 11 divisions, six first-line and five second-line, with but a single cavalry division.

Taking the East Prussian front as it appeared to the Russians, we can divide it militarily as follows:

(*a*) *Königsberg Area.*—A more or less fortified area extending over the Königsberg peninsula, of a depth of 19 m. from north to south. In the centre lay the obsolete fortress, strong against anything but heavy artillery. The area could be reinforced by sea through the canal from Pillau. It formed a strong flanking position from which to attack any force to the south.

(*b*) *Insterburg Gap.*—A gap of 43 m. of open country, down which ran the main Insterburg-Allenstein railway. The River Angerapp running north and south blocks this gap. It formed an excellent line of defence with the right flank resting against the impassable Lake Mauer.

(*c*) *Masurian Lakes.*—A line of continuous lakes from Angerburg to the Russian frontier at Johannisburg, a distance of 50 miles. The narrow gaps between the lakes could be held with few troops, and the whole line presented an almost impregnable front behind which the Germans could operate to either flank.

(*d*) *Johannisburg-Dzialdowo* (*Soldau*) *Front.*—A distance of 75 m. running east and west. On the Russian side the country had been left a desert as a defence against Germany.

The Russian Plan of Invasion.—The Russian plan for the invasion of East Prussia was to advance with two armies north and south of the line of lakes, with the object of enveloping the German forces supposedly concentrating behind this line. The northern army under Rennenkampf was to advance first, towards the Insterburg gap, with the object of drawing the Germans as far to the east as possible. The southern army under Samsonov was to advance to the line Rastenburg-Allenstein, with the object of striking the rear of the Germans opposing Rennenkampf.

Rennenkampf's army crossed the frontier on Aug. 17 with a strength of 6½ divisions and 5½ cavalry divisions. On the 20th an action was fought with the German VIII. Army at Gumbinnen. Prittwitz, the German commander in the East, had concentrated his main strength to meet Rennenkampf, six divisions and a cavalry division, whilst leaving some two divisions to face Samsonov's army, which was concentrating on the River Narew.

Rennenkampf had moved off without a great portion of his transport and found himself forced to halt on the 20th. Prittwitz advanced to attack him. There were serious miscalculations in the German movements, with the result that the action was indecisive, both sides suffering heavy losses. That evening the news arrived that Samsonov had not only started to advance, but that two of his corps were already close to the frontier and that he had at least five corps with him. The German commander abandoned all hope of defeating Rennenkampf on the 21st and contemplated a withdrawal to the Vistula. On communicating this on the telephone to the supreme command, he and his chief of staff were at once superseded.

The new commander, Hindenburg, had not yet been employed in the War. His chief of staff, Ludendorff, reached supreme headquarters at Coblenz on the 22nd and the situation in the East was explained to him. He immediately ordered the troops retreating in front of Rennenkampf to halt at once and to prevent him from pursuing, and issued instructions for a concentration against Samsonov. General Hindenburg joined Ludendorff's train at Hanover and took over the command at Marienburg on the 23rd.

Luckily for the new command, Hoffmann, the chief of the operations section under Prittwitz, had already carried out many steps facilitating the concentration desired by Ludendorff, and the situation, though alarming, had not grown worse since the supersession of Prittwitz. Samsonov's right was indeed well over the frontier near Ortelsburg and his left between Neidenburg

and Działdowo (Soldau) but the Russian advance appeared to be slowing up. The German XX. Corps had taken up a position north of Neidenburg and was awaiting attack. The leading units of the I. Corps were detraining south of Deutsch Eylau and were moving up on the right of the XX. Corps. The 3rd Res. division had detrained at Allenstein and was moving up on the left of the XX. Corps. A Landwehr division and units from the Vistula garrison troops were also coming up Thus, a strength of about six or seven divisions had been collected to oppose ten divisions and three cavalry divisions of Samsonov's army.

No decisive results could be expected from such strength, and decisive operations were the Germans' only hope. The most important feature of the situation, however, was that Rennenkampf had made no forward move since Gumbinnen and had lost all touch with the enemy in front of him. Ludendorff therefore conceived the idea of withdrawing all the troops from Rennenkampf's front, with the exception of the cavalry division, and of directing them against the right flank of Samsonov's army. Another four divisions thus obtained would give him an actual superiority over Samsonov and the direction of their attack might indeed be decisive.

An Account of the Battle.—Samsonov, who in peace time was the governor-general of Turkistan, had arrived from sick-leave in the Caucasus on Aug 12. He had seen neither his subordinate generals nor his staff before, and his immediate superior Jilinsky, commander of the north-western front, was urging him forward to cross the frontier on the 19th. The original concentration areas of his army behind the Bobr and the Narew had been considered to be too far to the east and a general move of all corps to the west was in progress. By the 20th, the right wing (VI. and XIII. Corps) had reached the frontier, with the 4th Cav. Div. well behind on the right. The left wing (XV. and I. Corps) was just short of the frontier, with the 6th and 15th Cav. Divs. covering it Of the XXIII. Corps, one division was two days' march behind the left wing and the other had not yet detrained at Warsaw The troops had been marching for a week across the desert area north of Ostrołeka, over execrable roads in very hot weather. Much of the transport had been left behind, the men were tired and unfed and numbers had been much reduced by sickness. No contact had been gained with the enemy and the army was already more than 24 hours late in crossing the frontier. Reports from Rennenkampf of his victory at Gumbinnen and, during his advance westwards on the 24th and 25th, of the signs of a hurried retreat on the part of the Germans, brought further urgings from Jilinsky to Samsonov to hurry. Samsonov obeyed to the best of his ability, and by the morning of the 26th his position was as follows:—

His centre of two corps (XIII and XV) was advancing north-west and was close on the line Allenstein-Hohenstein. On his right was one corps (VI.) and the 4th Cav. Div at Rothfliess, at two days' march from the centre On his left was a corps (I.) and the 6th and 15th Cav. Divs. near Koschlau, at one day's march from his centre. The XXIII. Corps troops which were up were moving into the gap between the centre and the left. His forces were thus much dispersed.

Reconnaissance had been bad and he had little information as to the enemy's dispositions He seems to have thought that the Germans flying in front of Rennenkampf had already crossed his front in their march to the Vistula and that he was too late to cut them off. He had deviated from his instructions to advance with his left on Allenstein and now had practically the whole of his force to the west of that town. He had no knowledge of the whereabouts of Rennenkampf's army and did not realize that he was increasing the space between the two Russian armies and thereby facilitating the German operations. His supply system had broken down utterly and his men were half-famished and worn out with the fatigue of excessive marching. The signal service had also broken down and orders had been sent out to corps by wireless. The Russian signals were easily read by the Germans, who thus had absolutely accurate information as to their opponents' dispositions and intentions.

Germans Attack Samsonov.—The new German Command had galvanized the dispirited VIII. Army from the first and hope of success ran high. The attacks on Samsonov's two flanks were to be launched simultaneously on the 26th. On the right, the German I. Corps, strengthened by the Vistula garrisons, attacked only half-heartedly. François, the commander of the I. Corps, was short of some of his heavy artillery and he contented himself with driving in some of the Russian outposts. On the 27th, however, he launched his attack in earnest. At dawn a hurricane bombardment was opened on the Russian I. Corps' positions on either side of Uzdowo. The famished Russians did not wait for the infantry attack but broke and ran. By 10 P.M. that night there was nothing left of the Russian left wing except a small rear-guard just north of Działdowo; and that too had disappeared before the next morning.

The rear of the Russian centre was now completely exposed and François directed his march on Neidenburg. Opposition there was none, and by the night of the 28th his leading troops had reached Muschaken, 8 m. E. of Neidenburg. By the night of the 29th the whole length of the road from Neidenburg to Willenberg was held by a line of entrenched pickets. The Russian retreat to the south was completely blocked. During the 30th François was attacked at Neidenburg by fresh Russian troops coming up from Mława and actually lost the town for a time. He held stoutly on to the line of his pickets, however, and on the 31st Neidenburg was reoccupied.

On the left, the German XVII and I. Res. Corps, having turned their backs on Rennenkampf and marched due south, had arrived within striking distance of the Russian right at Rothfliess on the night of the 25th. Their attack on the morning of the 26th came as a complete surprise. The Russian VI. Corps withdrew in confusion, losing 6,000 men and 16 guns. By the night of the 27th the Russian right was 32 m. S of Rothfliess and in a state of hopeless demoralization The rear of the Russian centre was now exposed on its other flank The German XVII Corps continued its march to the south, whilst the I. Res Corps moved in closer towards Allenstein. The story of the fighting in the Russian centre is not so inglorious as that on the two flanks. In accordance with Samsonov's plan the centre (XIII and XV Corps) continued their advance on the 26th towards the line Allenstein-Hohenstein The XIII Corps encountered no opposition, but the XV had to fight its way steadily forward. For the 27th, the advance was to be continued.

Second German Blow.—Ludendorff, with his accurate information of the events on either flank, now decided that the German centre had retired enough. The reinforced XX. Corps was therefore ordered to attack on the 27th The battle which ensued between the Russian XV Corps and the German XX Corps was particularly fierce, the Russians holding their own and even advancing a little on their left. The Russian XIII. Corps rendered no help to its neighbour. On the 28th the Germans renewed their attacks and this time the hardly-tried Russian XV Corps commenced to break. The XIII Corps, moving down to assist, found itself assailed in rear by troops arriving from Allenstein and for the second time brought no help.

When night fell the two Russian Corps were on a line from Griesliene to Waplitz and in close touch with the Germans Hoping to escape from pursuit, they commenced to withdraw during the night. The withdrawal soon became a rout, and a mass of troops and transport, both unfed and unwatered, became inextricably mixed in the depth of the Forest of Grunfliess Determined attempts were made during the 29th to break through to the south of Muschaken and to the north at Kaltenborn, but the German ring held fast Only some 2,000 men effected their escape. The greater portion of these two corps surrendered to the German parties clearing the forest during the 30th and 31st.

Samsonov himself had moved up to Neidenburg on the 27th in order better to control the battle. He was greeted with the news of the disaster to both his flanks and met streams of stragglers coming into the town. He decided to go to the headquarters of the XV. Corps and take personal charge, and left Neidenburg on the morning of the 28th with a small staff, all mounted on horses.

At once he became mixed in the mass of transport in the forest and could exercise no effective command. He then decided to ride to the south, but during the night of the 28th–29th he became exhausted after having walked for some distance. He drew aside in the darkness and his staff heard a single shot. A careful search brought no result and the staff continued their way, certain that their unfortunate commander had taken his own life in his despair at the turn which events had taken.

Results.—The practical result of the fighting from Aug. 26–30 was the total annihilation of two Russian corps and the reduction of three other corps to half their strength in numbers. The whole Russian II. Army was so demoralized and was so deficient in essential material, such as artillery and transport, that it was no longer of any fighting value. The Germans claimed 125,000 prisoners and 500 guns It is certain that their booty was very great, for 60 train loads of captured material left Puchallowen after the battle and the captured horses were driven in herds to improvised camps at Neidenburg. Although greatly inferior in the whole eastern theatre, the Germans had yet managed to concentrate a superiority on the field of battle. The Russians had 132 battalions, 96 squadrons and 620 guns, including 12 heavy, whilst the Germans had 155 battalions, 48 squadrons and 818 guns, including 128 heavy.

(W. E. I.)

TANNER, HENRY OSSAWA (1859–), American artist, of Negro descent, was born at Pittsburgh, Pa., on June 21, 1859. He was the son of Benjamin Tucker Tanner (born 1835), who became bishop of the African Methodist Episcopal Church in 1888. Henry Tanner was a pupil of Thomas Eakins, in Philadelphia, and of J. P. Laurens and Benjamin Constant in Paris. He first exhibited at the Salon in 1895. Examples of his work are in the galleries of the Luxembourg, Chicago, Des Moines, Los Angeles, etc. His "The Destruction of Sodom and Gomorrah" (1925) is in the Metropolitan museum, New York. He is a knight of the Legion of Honour, a member of the Paris Society of American Painters, of the American Art Association in Paris and of the National Academy of Design, New York.

TANNHÄUSER or TANHUSER, German Minnesinger of the 13th century, who lived for a time at the court of Frederick II., duke of Austria. After Duke Frederick's death he was received at the court of Otto II., duke of Bavaria; but he spent much time in wandering about Germany. He also went as a Crusader to the Holy Land. His poems belong to the decadence of the Minnesang, and combine a didactic display of learning with descriptions of peasant-life. His adventurous life led him to be identified, in the popular imagination, with the knight Tannhäuser who, after many wanderings, comes to the Venusberg, or Hörselberg, near Eisenach. He enters the cave where the Lady Venus—the Frau Hulda of German folk-lore—holds her court, and abandons himself to a life of sensual pleasure. By and by he is overcome by remorse, and, invoking the aid of the Virgin Mary, he obtains permission to return for a while to the outer world. He then goes as a pilgrim to Rome, and entreats Pope Urban to secure for him the forgiveness of his sins. The pope declares it is as impossible for him to be pardoned as for the staff he has in his hand to blossom. Tannhäuser departs in despair, and returns to the Venusberg. In three days the staff begins to put forth green leaves, and the pope sends messengers in all directions in search of the penitent, but he is never seen again. The legend has been reproduced by several modern German poets, and by Richard Wagner in the famous music drama.

For Tannhäuser's lyric poetry, *see* F. H. von der Hagen's *Minnesinger*, ii. (1838); K. Bartsch, *Deutsche Liederdichter des 12. bis 14. Jahrhunderts* (3rd ed. 1893), No. 47. *See* also F. Zander, *Die Tannhäusersage und der Minnesinger Tannhäuser* (1858); J. G. T. Grässe, *Die Sage von Tannhäuser* (1846; 2nd ed. 1861); A. Öhlke, *Zu Tannhäusers Leben und Dichten* (1890); J. Siebert, *Tannhäuser, Inhalt und Form seiner Gedichte* (1894).

TANNIN or **TANNIC ACID,** the generic name for a widely disseminated group of vegetable products, so named from their property of converting raw hide into leather (*q.v.*). They are soluble in water, and their solutions which have an acid reaction and an astringent taste, are coloured dark blue or green by ferrous salts, a property utilized in the manufacture of ink (*q.v.*). Some tannins appear to be glucosides of gallic acid, since they yield this acid and a sugar on hydrolysis, *e.g.*, oak tannin, whilst others yield protocatechuic acid and phloroglucinol, *e.g.*, moringa-tannin; common tannin, however, is a digallic acid.

Common tannin, or tannic acid, $C_{14}H_{10}O_9 \cdot 2H_2O$, occurs to the extent of 50% in gall-nuts, and also in tea, sumach and in other plants. It may be obtained by extracting powdered gall-nuts with a mixture of ether and alcohol. When pure the acid forms a colourless, amorphous mass, very soluble in water, less so in alcohol, and practically insoluble in ether. It may be obtained artificially by heating gallic acid with phosphorus oxychloride or dilute arsenic acid; and conversely on boiling with dilute acids or alkalis it takes up a molecule of water and yields two molecules of gallic acid $(HO)_3C_6H_2 \cdot CO_2H$.

The tannin of oak, $C_{19}H_{16}O_{10}$, which is found, mixed with gallic acid, ellagic acid and quercite, in oak bark, is a red powder; its aqueous solution is coloured dark blue by ferric chloride. The tannin of coffee, $C_{30}H_{18}O_{16}$, found in coffee beans, is not precipitated from its solutions by gelatin. Hydrolysis by alkaline solutions gives a sugar and caffeic acid; whilst fusion with potassium hydroxide gives protocatechuic acid. Moringa-tannin or maclurin, $C_{13}H_{10}O_6 \cdot H_2O$, found in *chlorophora tinctoria,* hydrolyses on fusion with caustic potash to phloroglucinol and protocatechuic acid. Catechu-tannin occurs in the extract of *Mimosa catechu;* and kino-tannin is the chief ingredient of kino (*q.v.*). Tannic acid is employed either alone or in conjunction with antimony salts as mordant in dyeing cotton with basic colouring matter.

Medicine.—Tannic acid is officinal in both the British and United States pharmacopoeias. It is incompatible with mineral acids, alkalis, salts of iron, antimony, lead and silver, alkaloids and gelatin. The British pharmacopoeial preparations are (1) *glycerinum acidi tannici;* (2) *suppositoria acidi tannici;* (3) *trochiscus acidi tannici.* The United States also has a *collodium stypticum* and an ointment. The intestine tannic acid controls intestinal bleeding, acting as a powerful astringent and causing constipation; it has been recommended to check diarrhoea.

Tannic acid is used in the treatment of various ulcers, sores and moist eruptions. The glycerin solution is used in tonsilitis and the lozenges in pharyngitis. For bleeding haemorrhoids tannic acid suppositories are useful, or tannic acid can be dusted on directly. The collodium stypticum is a valuable external remedy. Tannic acid is absorbed as gallic acid into the blood and eliminated as gallic and pyrogallic acids, darkening the urine.

TANNING, a term describing the conversion of natural skins into leather. The word *tan* means the bark of the oak, which contains tannin or tannic acid; this has the power to combine with skin-fibre and render it imputrescible. Modern tannage may be (1) vegetable tanning, *i.e.*, performed with the water extract of barks, woods, nuts, etc., containing tannin; (2) mineral tanning, principally with compounds of chromium or aluminium; (3) combination mineral and vegetable tanning; (4) oil tanning, *i.e.*, chamois leather. (*See* LEATHER.)

TANTA, a town of Lower Egypt, in a central position nearly midway between the two main branches of the Nile, and converging-point of several railways traversing the Delta in all directions. It has a population of 57,000, is the capital of the rich province of Gharbia, and is noted for its fairs and Muslim festivals, which are held three times a year and are sometimes attended by 200,000 pilgrims and traders.

TANTALUM, a metallic chemical element belonging to a family of three metals which includes vanadium (*q.v.*) and columbium (*q.v.*). It occurs in certain rare but widely distributed minerals usually associated with columbium. Columbite (Massachu-

setts), the native ferrous columbate, $Fe(CbO_3)_2$, and tantalite, ferrous tantalate, $Fe(TaO_3)_2$, frequently contain both columbium and tantalum with manganese partially replacing iron. Fergusonite is a complex columbo-tantalate of iron and the rare earth metals, samarskite has an even more complicated composition since it also contains uranium. It is accordingly not surprising that the history of tantalum is closely intermingled with that of columbium, some confusion having arisen formerly in regard to the separate identities of these closely allied metals Struverite, a titaniferous tantalum ore ($TiO_2$46·0%, Ta_2O_5 36·0%) found extensively in Malaya, is a valuable source of both tantalum and titanium.

The first successful application of tantalum was as a filament for the incandescent electric lamp, but for this purpose it has now been superseded by tungsten.

Separation and Extraction.—Tantalum is extracted from the foregoing minerals by one of the following processes:—(i.) Fusion with potassium fluoride and extraction of the melt with dilute hydrofluoric acid On evaporating the solution, potassium tantalifluoride, K_2TaF_7, separates first, as one part of this salt is soluble only in 155 parts of cold water, whereas potassium columbium oxyfluoride, K_2CbOF_5, H_2O, being soluble in 12–13 parts of water, is obtained on further concentration (ii.) Alkali fusion with sodium peroxide, caustic potash or potassium carbonate and acidification of the melt with dilute hydrochloric acid, when on boiling, the oxides Cb_2O_5 and Ta_2O_5 are precipitated. (iii.) Fusion with potassium bisulphate, and extraction with acidified water, removal of tin and tungsten with ammonium sulphide and of silica and titania with hydrofluoric and sulphuric acids. Final neutralisation with ammonia and boiling with salicylic acid leads to precipitation of the two pentoxides

Metallic tantalum was first obtained by Berzelius (1820) on heating potassium tantalifluoride with potassium; a more modern procedure is to reduce it in an evacuated electric furnace with either potassium or sodium. The product compressed and fused in the electric furnace with exclusion of air led to the pure metal (W. von Bolton, 1905). Moissan reduced the pentoxide with carbon in the electric furnace (1902). Other methods of obtaining the metal include electrolysis of the fused K_2TaF_7 or of tantalum compounds in dilute sulphuric acid

Tantalum (symbol Ta, atomic number 73, atomic weight 181·5) is a white metal; its melting point is 2,850° C and its specific gravity 16 6. It is very ductile and malleable with considerable toughness It may be drawn into very thin wires Its tensile strength is greater than that of steel or platinum; its coefficient of expansion is less than that of the latter metal so that it may be sealed into glass. On heating, it absorbs large volumes of hydrogen or nitrogen and these gases are only removed by heating to fusion in a vacuum. It resists all single acids except hydrofluoric and hot concentrated sulphuric acids.

Applications.—Because of its resistance to corrosive agents tantalum may be used instead of platinum in standard weights and crucibles. Chemical apparatus in ductile tantalum, which is much cheaper than platinum, excels in its degree of resistance to acid corrosion. Metals may be deposited electrolytically on tantalum cathodes and since tantalum is not attacked by aqua regia the metallic deposit may be removed completely. Tantalum is claimed to surpass steel for surgical instruments and special tools, since these do not rust. It is used extensively as an electrolytic valve since it has the property shared with certain other metals of allowing electric current to pass in one direction only when immersed in acid. But unlike most metals, it is not subject to acid corrosion and hence it makes an ideal material for rectifiers and under the trade name of "Balkite" it forms the essential constituent of many rectifying units.

Compounds of Tantalum.—The pentoxide, Ta_2O_5, is a white infusible mass obtained by heating the metal in oxygen or by igniting tantalic acid.

Tantalic acid, $HTaO_3$, is a gelatinous precipitate obtained on adding water to tantalum pentachloride; it dissolves in aqueous alkalis to yield solutions of alkali tantalates, and is soluble in hydrofluoric acid to form tantalum pentafluoride (colourless prisms, m.p. 97°, b.p. 229° C). Addition of potassium fluoride to the pentafluoride solution gives potassium tantalifluoride which crystallises in needles. Solutions of tantalates furnish insoluble yellow tantalum ferrocyanide. Tantalum pentachloride, white hygroscopic needles melting at 211° C, and boiling at 241·6° C, is produced by heating the pentoxide to redness in a stream of chlorine and carbon tetrachloride. A suboxide (hypotantalic oxide) $(TaO_2)_x$, is a grey mass produced by heating the pentoxide with carbon, or magnesium; the corresponding sulphide, TaS_2, results from the action of hydrogen sulphide and carbon disulphide on the heated pentoxide.

Tritantalum hexachloride ("tantalum dichloride") Ta_3Cl_6, formed by heating the pentachloride with lead at 600° C, is extracted with hydrochloric acid and left as a green precipitate on evaporating *in vacuo*. Saturation of the extract with hydrogen chloride yields the green crystalline tritantalochloric acid $[Ta_3Cl_7,H_2O]H,3H_2O$. Acids of mixed type

$$[Ta_3Cl_6Br,H_2O]H,3H_2O \text{ and } [Ta_3Cl_6SO_4]H_2,$$

are obtained by the use of hydrogen bromide and dilute sulphuric acid respectively. In these compounds tantalum is bivalent, and analogous substances have been prepared containing bivalent molybdenum and tungsten (K. Lindner and others, 1924)

(G. T. M)

TANTALUS, in Greek legend, son of Zeus or Tmolus and Pluto (Wealth), daughter of Himantes, the father of Pelops and Niobe. He was the traditional king of Sipylus in Lydia (or of Phrygia), and was the intimate friend of Zeus and the other gods, to whose table he was admitted. But he abused the divine favour by revealing to mankind the secrets he had learned in heaven (Diod. Sic iv. 74), or by killing his son Pelops (*q v*) and serving him up to the gods at table, in order to test their power of observation (Ovid, *Metam* vi 401); another story was that he stole nectar and ambrosia from heaven and gave them to men (Pindar, *Ol.* i. 60); a fourth that he was guilty of perjury (Antoninus Liberalis, 36). The punishment of Tantalus in the lower world was famous. He stood up to his neck in water, which flowed from him when he tried to drink of it; and over his head hung fruits which the wind wafted away whenever he tried to grasp them (*Odyssey*, xi. 582). This myth is the origin of the English word "tantalize." Another story is that a rock hung over his head ready to fall and crush him (Euripides, *Orestes*, 5). The sins of Tantalus were visited upon his descendants, the Pelopidae Ancient historical reminiscences and natural phenomena, especially volcanic catastrophes, are at the bottom of the legend. The tomb of Tantalus on Mt. Sipylus was pointed out in antiquity, and has been in modern times identified by C. F. Texier with the great cairn beneath Old Magnesia, but Sir W. M. Ramsay inclines to a remarkable rock-cut tomb beside Magnesia

The story of Tantalus is an echo of a semi-Greek kingdom, which had its seat at Sipylus, the oldest and holiest city of Lydia, the remains of which are still visible. There was a tradition in antiquity that the city of Tantalus had been swallowed up in a lake on the mountain; but the legend may, as Ramsay thinks, have been suggested by the vast ravine which yawns beneath the acropolis.

See PELOPS, PHRYGIA; Sir W. M. Ramsay in *Journal of Hellenic Studies*, iii.; Frazer's *Pausanias*, iii. p. 555; v., p. 392; J. Hylen, *De Tantalo* (Uppsala, 1896).

TANTIA TOPI (*c.* 1819–1859), rebel leader during the Indian Mutiny, was a Mahratta Brahman in the service of Nana Sahib. He instigated the massacre of Cawnpore, and commanded at the battle of Bithur, where he was defeated by General Havelock. With the aid of the Gwalior contingent he pressed General Windham hard at Cawnpore on Nov. 27–28, 1857, but was defeated by Sir Colin Campbell on Dec. 6. Together with the Rani of Jhansi he was besieged by Sir Hugh Rose in the Jhansi fort, but escaped and collected a force of 20,000 men which Sir Hugh defeated without relaxing the siege. This was the decisive action of the campaign in Central India, and Tantia Topi was obliged to seek refuge in the jungles of Rajputana and Bundelk-

hand, where he was taken by Major Meade, condemned and executed on April 18, 1859. He was the only rebel leader in the Mutiny who showed any conspicuous military ability. (*See* INDIAN MUTINY.)

TAOISM. The term Taoism has two meanings: (1) the philosophical system attributed to Lao Tzu (b. 604 B.C.) and Chuang Tzu (b. 330 B.C.); (2) the popular religion of the Chinese.

Taoism as a Philosophical System.—The term Tao originally meant the revolution or the way of the heavens about the earth. This movement of the heavens was regarded as the cause of the phenomena on earth. The Tao was located about the celestial pole, which was considered to be the seat of power because all revolves about it. In the course of time this concrete expression became abstract, and the Tao was viewed as the universal cosmic energy behind the visible order of nature. This cosmic energy regarded as *being* is impersonal, omnipresent and eternal; viewed as *becoming* it works spontaneously, orderly, unselfishly and continuously for the highest good of all beings.

TAOIST PRIEST IN FULL COSTUME, CANTON, CHINA

The Tao produced the *yin* and the *yang*, the negative and the positive, female and male principles of nature. These by their interaction brought forth heaven and earth. Heaven and earth gave birth to all beings. The human order is the product of the eternal energy.

Philosophic Aspect.—Taoism has usually been regarded as a mystic religion, but it was also an economic and political philosophy. It advocated frugality, simplicity and the joys of the peasant life in contact with the soil. It opposed the educational programme of the Confucianists, and advocated the theory that the people should be kept in innocence (not in ignorance). The Taoist philosophy is responsible for that remarkable trait of the Chinese, namely, their contentment in situations which offer a minimum of comfort and their prizing of culture above possession.

Political Aspect.—In politics Taoism opposed a highly centralized government and favoured the maximum autonomy for the people. Lao Tzu and his successors promoted the small village state which enjoyed full autonomy and lived in harmony with its neighbours. All forms of bondage and legal restraints were opposed. Non-resistance was exalted and militarism was condemned.

The ethics of Confucianism met with the strongest opposition on the part of the Taoists. Such virtues as love, justice, reverence, wisdom and sincerity were regarded as the first steps departing from the harmony of the simple life in the Tao, and producing the distracting contraries which marred the purity of life.

The Taoists were mystics, but they were practical mystics, who hoped to realise the best social order through a harmonious relationship with the Tao. Their ideal was "this worldly." Their mysticism had three stages: (1) the purgation, casting out selfishness and self-seeking; (2) union with the Tao, by which the individual lost his individuality with the distraction of the contraries; (3) power, which enabled the individual merged with the Tao to escape the limitations of time and space.

Taoism as a Religion.—Taoism as a religion is inherent in Taoism as a philosophy. The early mystics practised breathing and abstaining from food, and sought longevity and a future life in the Taoist paradise. The religious aspect did not become prominent, however, until the Han dynasty (206 B.C.–A.D. 221), when the Taoists occupied themselves in compounding the elixir of life and in making journeys to the Isles of the Immortals. They also developed several sects which practised exorcism and fortune-telling and exercised considerable political power.

The rise of Taoism as a church is attributed to Chang Tao-Ling (b. A.D. 34), who developed a high degree of magic power which he transmitted to his heirs, together with the political prestige which reputation for such power brought. These took part in a successful rebellion in the latter part of the 2nd century, and established a state in Szechuan based on Taoist principles. The descendants of Chang Tao-Ling were recognized by the Government and in 1016 were given a fief at Lung Hu Shan in Kiangsi. Their function consisted of a general oversight of the Taoist priests and monks and the rule over the world of the gods. The system developed a hierarchy among the gods which corresponded to that of the government of China. At the head was Yü Huang Shangti, the Pearly emperor, who presided over an elaborate pantheon.

Buddhist Influence.—Through contact with Buddhism in the first six centuries of our era the Taoists appropriated the Buddhist world view, adopted the monastic system and imitated the Buddhist pantheon. Lao Tzu was deified and was associated with Pan Ku and Yü Huang Shangti in the Taoist Trinity patterned after the Three Jewels of Buddhism. Present-day Taoism is a conglomeration of animism, polytheism and magic.

TAORMINA, a town on the east coast of Sicily (ancient *Tauromenium*), in the province of Messina, from which town it is 30 m. S.S.W. by rail. Pop. (1921) 4,980. It is a favourite winter resort, chiefly on account of its fine situation and beautiful views. It lies on an abrupt hill 650 ft. above the railway station, and was occupied at least as early as the 8th cent. B.C. (as the discovery of a Sicel cemetery of that period shows). It was refounded by the Carthaginian Himilco in 397 B.C., after the destruction, by Dionysius the Elder of Syracuse, of the neighbouring city of Naxos. In 392 Dionysius occupied it and settled his mercenaries there. In 358 the exiles from Naxos at last found a home there. It was the city at which both Timoleon and Pyrrhus first landed. During the First Punic War it belonged to the kingdom of Hiero, and after his death it was allied to Rome. During the first Servile War it was occupied by Eunous and some of his followers, but was at length taken by the consul Publius Rupilius in 132. It was one of the strongholds of Sextus Pompeius, and after defeating him Augustus made it into a *colonia*. In the time of Strabo it was inferior in population to Messana and Catana; its marble, wine and mullets were highly esteemed. In A.D. 902 it was taken and burnt by the Saracens; it was retaken in 962, and in 1078 fell to the Normans.

The ancient town perhaps had two citadels; one the hill above the town to the W., now crowned by a mediaeval castle, the other the hill upon which the theatre was afterwards constructed. There are some remains of the city walls. The church of San Pancrazio, just outside the modern town, is built into a temple of the 3rd century B.C., dedicated to Serapis, the south wall of the cella of which is alone preserved. The other ruins belong in the main to the Roman period. The theatre, largely hewn in the rock, is of Greek origin, but entirely reconstructed. The stage and its adjacent buildings, especially the wall, in two storeys, at the back, are preserved. The view is of exceptional beauty, Mount Etna being seen from the summit to the base on the south-west, while to the north the rugged outlines of the coast and the mountains of Calabria across the sea to the north-east make up one of the most famous views in the world. There are also remains of a much smaller theatre (the so-called Odeum), and some large cisterns; a large bath or tank which was apparently open, known as the Naumachia, measures 426½ ft. in length and 39½ in width. There are remains of houses, tombs, etc., of the Roman period, and fine specimens of Romanesque and Gothic architecture (notably the Palazzo Corvaia) in the modern town.

See Rizzo, *Guida di Taormina e dintorni*, Catania, 1902.

TAPACULO, the name given in Chile to a bird (*Pteroptochus albicollis*) and applied in an extended sense to its allied

forms, which constitute a small Passerine family, *Pteroptochidae*, peculiar to South America. About 20 species are known.

The true tapaculo (*P. albicollis*) has a resemblance to the females of some of the smaller shrikes (*Lanius*), but differs in its shortened wings and powerful feet. It rarely flies, hops actively on the ground or among bushes with its tail erect, and continually utters various and strange notes—some, says Darwin, are "like the cooing of doves, others like the bubbling of water, and many defy all similes" The Turco, *Hylactes megapodius*, is larger, with greatly developed feet and claws, but is very similar in colour and habits. The Turco is distributed through central and northern Chile.

TAPANULI, a residency on the west coast of Sumatra, D. E. Indies, area, 38,227 sq.km., bounded north by Achin, east by the government of the East Coast of Sumatra, south by the residency of Sumatra West Coast, and west by the Indian Ocean. It is very mountainous, but has flat stretches of alluvial land on the coast between spurs of the great central range of mountains which traverses the length of the residency from north to south and forms a great massif from the centre of the residency to its eastern border which includes the mountain lake Toba, along the eastern shore of which the Tapanuli boundary runs. This lake, regarded as holy, was not seen by a European until 1863 (van der Tuuk). Previous attempts to reach it met with disaster, three Frenchmen and two Americans being murdered on their way to it, in 1835, while, in 1850, Ada Pfeiffer was obliged to turn back on account of native hostility. The lake, which is 3,000 ft. above sea level, is 56 m. long, with an area of 23 sq.m. and a greatest depth of 1,500 feet. It has a large hilly island, Samosir, in the centre, divided from the mainland on the west by a narrow channel. It is bordered on all sides by steep rocks, overhung with vegetation, and surrounded by mountains, and affords magnificent views. A good motor road runs to it from the coast, and there is a road around the lake from Balige to Prapat. There is also a motor boat service.

The mountains of Tapanuli include Malea, in the south, 6,545 ft., Ulu Darat, in the centre, 7,010 ft., and Sibutan, on the north-eastern border, 7,972 ft Small rivers flow westwards from the mountains to the sea, the Gadis, Turu and Sibundong, but they are almost useless for navigation. The coast is either rocky or marshy, but in Tapanuli Bay, which is surrounded by mountains and shut off from the effects of the south-west monsoon by Morsala Island, there is a good harbour with secure anchorage. Cultivation is confined to the valleys and the flat coastal strips, where maize, rice, coco-nuts, coffee, nutmegs and rubber are grown. Gold and silver are known in close association. Pop. (1927) 895,416, largely Batak. The inhabitants consist of Mohammedans and Christians, whilst many remain pagans, with traces of Hinduistic practices mingled with their animism. (*See* SUMATRA) They grow rice, coffee, tobacco and maize, also fruit and vegetables, and keep horses, cattle, pigs and buffaloes, build picturesque houses, are patriarchal in society, and are good craftsmen in wood, ivory and copper, whilst the women weave their own clothes. Cannibalism has been shed, and as the country becomes more opened up the Bataks become more amenable to outside civilizing influences. They have many languages.

The capital and chief port of Tapanuli is Sibolga, pop. 5,822, the headquarters of the Resident, which is connected by road with Lake Toba and the interior generally, and, by the road round the southern end of Lake Toba, with Pematang Siatar, the terminus of the Sumatra West Coast railway, giving access to Medan and Belawan on the coast. A road through the Padang Highlands connects Sibolga with Padang, and a branch from this leads to Natal, a small port on the coast, in the south, whilst there is road connection between Sibolga and Barus, a small port in the north, connected by cable and overhead telegraph with Padang, and, by vessels of the Royal Packet Navigation Company between Barus, Sibolga, Natal and Padang, Bencoolen and Batavia. Exports (1926), were 14,899,537 and imports 5,072,923 guilders. Tapanuli was annexed piecemeal by the Dutch during the nineteenth century.

TAPE MACHINE: *see* TICKER.

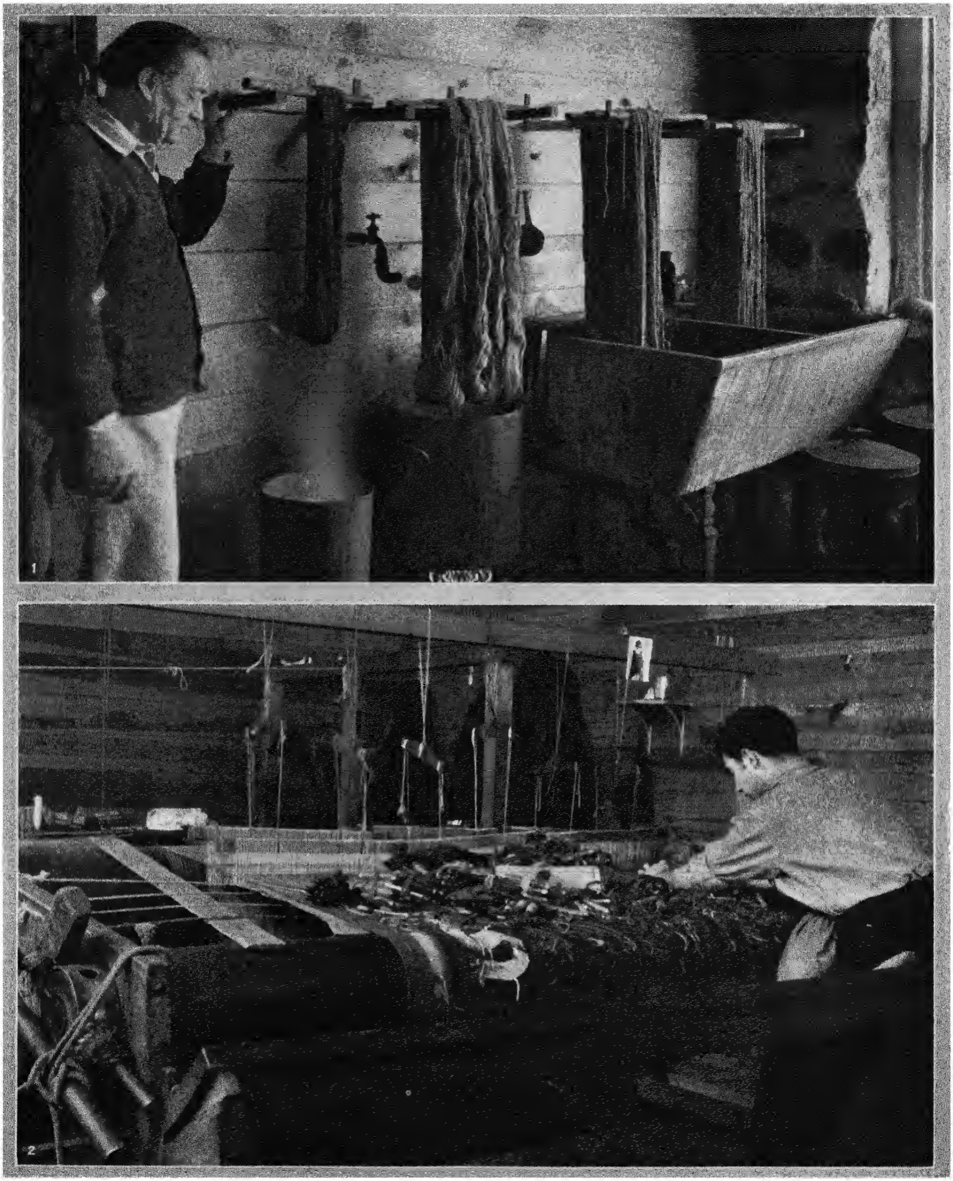
TAPESTRY, a term that came to be applied, in English, to stout woven materials of various kinds for hangings, curtains, coverings and upholstery. The word is also heir of the term "arras," so called from the city in Flanders, but has gained a technical meaning of its own. It is in this latter sense that the word is to be used in this article. Much that used to be called tapestry is not included, while everything that was formerly called arras comes within its scope. The differentiation between tapestry and arras continued into the 17th century. George Herbert, in *The Temple* (1633), writes of "the cloth of State . . . not of rich arras, but mean tapestrie." The elimination of the word "arras" and the assumption of its meaning by "tapestry" was accomplished gradually during the 18th century.

Origin and Method.—Tapestry is a fabric woven by a primitive and very simple method. Whether the invention took place in one locality, thence becoming known throughout the world, cannot be decided from existing evidence. It is found in early times in places so far apart as Peru, Egypt and China and this is a good reason for the assumption that so obvious a method of weaving threads into a texture came naturally, wherever primitive mankind took to weaving at all. There is no simpler way of passing threads across one another, over and under, so as to form a coherent texture. It is really on account of this essential simplicity that it came to be used for the large and elaborate pictorial hangings which come first to the mind when the word "tapestry" is mentioned. The method is pliable in the hands of the worker, who is freed from the limitations of the power-loom. In the latter, the exact repetition of the design follows as naturally as the multiplication of copies of a printed book, while there is no more reason why tapestries should be alike than why paintings should be.

Like other woven fabrics, tapestry consists of warp and weft threads. The warp is the series of parallel threads set out on the loom to the width of the fabric. In some forms of primitive weaving, not yet entirely out of use in remote districts, these warps were hung from a beam, with a weight attached to the lower end of each separate thread to keep it relatively taut during the weaving process. A well-known representation of this form of loom is on a Greek vase from Chiusi, painted with a scene from the *Odyssey* in which Penelope delays her suitors by working at the loom, during the absence of Ulysses. The first step forward in method was that of securing both ends of the warp by stretching them across a rectangular frame With the subsequent addition of a simple contrivance for pulling forward the threads in succession in order to pass the weft through behind, the tapestry-loom was perfected for its work This frame or loom, with its parallel row of warp threads, is placed for weaving either upright, when it is known as "high-warp," or horizontally (low-warp) with the threads running directly away from the weaver. The former is the better method though the results in each case are approximately the same. Low-warp weaving is about one-third quicker, and the cost is usually about one-half that of high-warp tapestry.

The weft threads, which form the pattern, are inserted by hand, alternately over and under the warps, generally with the aid of a wooden bobbin, a pointed peg-like implement round which the thread is wound. This is the special feature of tapestry-weaving; there is no shuttle passing backwards and forwards right across the fabric, but the threads are only inserted to cover the particular space for each colour as required by the design. Thus a tapestry may be compared to a mosaic. In the large tapestry hangings of Europe the warps may be as few as ten to the inch, or as many as 30; in the majority of cases there are less than 20. The higher figure is often exceeded in the fine work such as the Chinese and the Egyptian.

Materials and Colours.—The high-warp weaver sits at the back of his loom, with the cartoon to be copied placed conveniently near him. A mirror hung before the warp on the other side enables him to gauge the effect as the work goes forward. The loose ends of the warp at the start and finish of each patch of colour are pulled through to the side at which he works, and are thus left to hang at the back of the finished fabric; otherwise back and



BY COURTESY OF THE EDGEWATER TAPESTRY LOOMS

STAGES IN THE PROCESS OF MODERN TAPESTRY WEAVING

1. The dyer with his vats. This stage is extremely important as weak colours or cheap dyes will ruin a well-designed tapestry. In America both silk and wool are used separately and in combination; but coloured wool, the surface of which absorbs light, is generally preferred. 2. View of a low-warp or horizontal loom showing the weaver at work. The cartoon is placed beneath the warp, and the design woven over it by hand, the feet meanwhile manipulating the two sets of leashes which form the sheds. Since the textiles are woven with the wrong side next to the weaver, the face cannot be seen until the tapestry is completed. In high-warp looms the warp is vertical

front are approximately alike. The wefts are inserted loosely and afterwards pressed down by an instrument like a comb, the teeth of which are thrust between the warps and beaten down until those threads are entirely covered by the wefts. The bobbins on which the threads for the weft are wound are usually pointed at one end, to serve on occasion the same purpose as the comb. The warp is a strong thread, generally of wool, linen or cotton. The weft is mostly of wool, silk or metal threads, and in elaborate work it is often of all three. The weaver does much, almost everything, to make or mar the beauty of a tapestry, but the cartoon he copies is seldom his own work. At Brussels a regulation in the 15th century debarred the weaver from designing anything more than accessory details. The cartoon is usually prepared by an artist specially qualified by training and experience. He may, and often does, base his work on a design by another artist. Quite frequently paintings, illuminations, drawings or engravings not originally intended for reproduction in tapestry are used as the basis of the cartoon. Whatever may be the size of these models the cartoon is approximately of the size the tapestry is to be; it is generally painted on paper, though linen appears to have been more usual in the middle ages. The main outlines of the design are traced upon the warps, but the weaver must constantly refer to the cartoon for guidance as he proceeds. It was not at all unusual for weavers to duplicate their work, or to copy existing sets of tapestries made by others. Among the weavers of Brussels in the 16th century copying each other's work was forbidden, but any restriction of this kind was local and exceptional.

The colours used for a simple pictorial subject may be as few as 12, and mediaeval tapestries seldom have more than 40. In early tapestries, gradation of tints was rendered by running one into another in projections like the teeth of a comb, or in cruder fashion by rings of colour comparable to the colouring of a contour-map. The method, introduced at a later time, of imitating the fusion of tones in a picture has led to the use of a large number of intermediary tints. The employment of a large or small number of tints, or of a fine or coarse texture does not necessarily affect the beauty, but only the character, of the finished fabric. When the painter Oudry, as inspector of the Gobelins factory in the 18th century, insisted on the imitation of the oil-colours of the painter's palette, in place of the *coloris de tapisserie* proper to the method, the number of tints had to be multiplied enormously, until the weaver had more than 10,000 different tints at his disposal. The increase in the number of tints employed has not been the only change brought about with the lapse of time. At first each colour was shaded with deeper tones of its own colour, and high lights were white. This simple method, resembling that of book-illumination, is productive of the most beautiful effects. At a later time yellow becomes the dominant colour, giving a unity recalling that often provided by the varnish on a picture. When gold and silver thread are freely used for salient points the limit of splendour is reached, but not without some sacrifice of true tapestry-effect.

Almost incredible pains were sometimes taken to see that materials and workmanship were of the best. Regulations were framed to this end, and the penalties for infringement were severe. Distinguished artists were engaged to watch the progress of the work. In the case of a set of tapestries woven at Brussels to commemorate the conquest of Tunis by the emperor Charles V. there were stipulations controlling the kind of thread to be used, and the proportion of metal thread to wool and silk. The emperor provided the gold and silk threads, and his agent spent more than two years at Granada supervising the preparation and dyeing of the silk. Eighty-four weavers were to be continually employed on the 12 panels, and a commission was appointed to superintend the work.

Early Examples.—The earliest specimens of tapestry-work which can be accurately dated were found in the year 1903 in the tomb of Thutmosis IV. (1420–1411 B.C.) at Thebes. They are now in the Cairo museum. There are three small examples, woven in coloured linen threads. One has the cartouche of Amenhotep II. (*c.* 1450 B.C.), and another that of Thutmosis III. (*c.* 1500 B.C.) inwoven in colours.

The skill shown in these very remarkable weavings points to a far older tradition, and though at present no other examples are known for 1,000 years after, there can be no reasonable doubt of continuity in the process of tapestry-weaving. The next examples about which we have certain knowledge are some fragments of garments found about 1872 in some Greek graves near Kertch in the Crimea, and now in the Hermitage museum at Leningrad. They are woven in coloured wools. One has a pattern of stags' heads and ducks, and another has rows of blossoms; the rest are mostly striped or plain. Two of the graves in which these specimens were found are of the 4th or 3rd centuries B.C.

Reverting to Egypt, after a gap of fifteen or sixteen hundred years from the date of the examples already mentioned, tapestry-weavings became abundant. Indeed there is much to confirm the theory that in the Graeco-Roman period, during the first few centuries of the Christian era, this was the principal method employed to produce a pattern in woven stuffs. Some examples are woven entirely by the tapestry-process, and among these a few are of a size and scale which warrant comparison with the tapestry-hangings of later days. One hanging found in a burying ground at Akhmîm on the Nile, and now in the Victoria and Albert Museum, has a pattern of birds and foliage on a red ground. The majority of the specimens from Egypt are panels and bands of ornament forming a continuous texture with the linen stuffs which provide the warps for the woollen tapestry-weaving. Examples preserved in the museums of Europe and America show a wide range of patterns of classical and early Christian origin. The method of weaving was continued in the Mohammedan period, from the 7th century onwards, when silk came into common use for the tapestry patterns, which are often of great fineness and elaboration.

It is beyond doubt that tapestry-work was done by the Romans, though no specimens have been found on Italian soil. In fact, but for those from Egypt, practically nothing of ancient Roman textile art has come down to our times. The Byzantines, too, were acquainted with it. A fine silk tapestry-hanging with an equestrian portrait of an emperor of the East was found in the tomb of Bishop Gunther, who died in the year 1064 on his way home from an embassy to Constantinople and was buried, enwrapped in this hanging, in Bamberg cathedral.

The Low Countries.—Tapestry weaving enters on a new phase, and one which reduces all others to relative insignificance, in the work of the Low Countries. How this great industry first arose there we do not precisely know, but it has been conjectured that the election of Baldwin of Flanders as emperor of the East in the year 1204, may have familiarized the Flemings with Byzantine work like that brought home by Bishop Gunther. However this may be, little more than the bare idea can have been derived from any outside source. The industry as it developed was characteristically Flemish, and in its turn it exerted a very wide influence upon the rest of Europe. The distinction between high-warp and low-warp tapestry-work, which now becomes significant, is first met with in the Low Countries at the beginning of the 14th century. To that time, or perhaps a little earlier, may be traced the origin of those large pictorial tapestries which soon brought the weaver into successful rivalry with the painter in the decoration of churches, halls, palaces and dwelling-houses. In the dukes of Burgundy, who acquired the Flemish provinces by marriage in the 14th century, the weavers found patrons of almost unlimited wealth and luxury. Arras was the first place to rise to fame. Its high-warp tapestry is mentioned in the early years of the 14th century, and the city gave its name to tapestry-work in England, as we have seen, as well as in other countries whither the tapestries of Arras were sent. By about the middle of the 15th century the pre-eminence of Arras was disputed by Tournai, but it is significant that the series of tapestries with scenes in the lives of SS. Piat and Eleutherius were woven at Arras for the cathedral of Tournai in the year 1402. During the course of the century the dukes of Burgundy gave large commissions to the weavers of Tournai, and near its close Pasquier and John Grenier obtained permission to import tapestries into England.

In the year 1477 Arras was captured by Louis XI. of France,

and the industry which had brought the city so much fame suffered a check from which it never recovered. Among other centres of tapestry-weaving were Audenarde, Bruges, Douai, Enghien, Ghent, Lille and Valenciennes, but Brussels began to take the place that Arras had lost, and from the early years of the 16th century until the end of the 18th it was the leading tapestry-weaving centre in the Low Countries. In the year 1528 an enactment required that all tapestries above a very moderate size woven at Brussels should bear the distinctive mark of the town as well as that of the maker. The former was a shield with a B on either side. The maker's mark was generally a monogrammatic device not easy to decipher and often impossible to identify, as the local records have perished. In later times the separate initials or the full name are often given. In the absence of definite records it is not easy, and often impossible, to distinguish the work of one factory from another, but as the example of Brussels in the use of a distinctive mark was shortly followed by all other factories of the Low Countries, clues to a classification were provided. Difficulties do not end entirely at this stage, since the selvedges, where the marks were placed invariably at first, and usually at a later time, are not often intact in tapestries of the 16th century.

The best known and the most frequently repeated of the tapestries woven at Brussels was the famous set of the "Acts of the Apostles," designed by Raphael for Pope Leo X., and woven at Brussels by Peter van Aelst during the second decade of the 16th century. When hung in their destined position round the walls of the Sistine chapel of the Vatican, they evoked the greatest enthusiasm. Another set woven shortly afterwards and now in the Berlin museum is believed to be the set given by the pope to Henry VIII. of England, and sold with the effects of Charles I. Numerous other repetitions were woven at Brussels, and afterwards they were copied at Paris and Beauvais. There were originally ten subjects. In the year 1630 seven of the cartoons (presumably three had perished) were bought by Charles I. of England, on the advice of Rubens, to be reproduced in tapestry at the factory at Mortlake established not long before, and many sets were woven there in subsequent years.

Bernard van Orley, the follower and imitator of Raphael, also designed subjects for the weavers of Brussels. He was succeeded by a number of lesser-known artists of the Netherlands. In the 17th century, Rubens was engaged to make numerous cartoons, and his example was followed by Jacob Jordaens and other contemporaries. A little later the works of Teniers were very frequently copied. During the 17th century the factories of Brussels were busily occupied, but towards the end of that period the rise of the Gobelins factory at Paris, and in the 18th century the growing use of wall papers, exerted a pressure which was severely felt. It is said that early in the 18th century the number of weavers was hardly more than one-tenth of those employed a century before, and during the course of the century there was a further decrease until at the last one atelier alone remained, that of Jan van der Borght. In the year 1794 this too was closed, and the industry which had given distinction to Brussels for three centuries came to an end. During the greater part of this time its prestige in the Netherlands was hardly disputed, yet other factories had a career of fluctuating prosperity. An edict of the Emperor Charles V. in the year 1544 shows that tapestries were then being woven at Brussels, Louvain, Bruges, Audenarde, Alost, Enghien, Binche, Ath, Lille, Tournai and a few other places. Antwerp is also mentioned, but the extent to which tapestries were actually made there is uncertain. The city had then taken the place of Bruges as the chief *entrepôt* of commerce in the Netherlands, and a gallery was provided for the display of tapestries on sale. Henry VIII. of England had his agents there, ostensibly for the purchase of tapestries, but actually in search of political intelligence. English agents were again there at the end of Elizabeth's reign. Large numbers of tapestries were sent from Antwerp to Spain, where Flemish tapestries were much in demand. In the collections of the Spanish Crown at the present time there are 422 of them.

The range of subjects covered by the tapestries of the Low Countries can only be indicated here in the briefest outline—legends of antiquity (*e.g.*, the Trojan war; the adventures of Ulysses; Romulus and Remus); scenes from ancient history (the life of Alexander; Julius Caesar); stories of the gods (Apollo, Diana, Vulcan, Venus, Hercules); the Old and New Testament (from Genesis to Revelation); the lives of saints (innumerable); the legends of chivalry (Charlemagne); mediaeval histories and allegories (the story of Herkinbald; Petrarch's *Triumphs;* the months; the seasons); contemporary history (Charles V.'s conquest of Tunis; adventures of João de Castro, viceroy of the Portuguese Indies); scenes of peasant life (Gombaut and Macée subjects after Teniers); sport (hunting, archery); heraldry, landscapes, verdures and decorative panels. Some of these were newly designed from time to time (for example, the life of Alexander is found in the 14th, 15th, 16th, 17th and 18th centuries), but many were reproduced again and again from old cartoons or tapestries. In instances of the latter kind, the borders are more characteristic of the period of production.

It is not uncommon for early tapestries to be divided up by Gothic pillars and arches after the fashion of a mediaeval folding altar-piece. Sometimes scrolls with explanatory inscriptions run along above and below the scenes. In the latter part of the 15th century a narrow band filled with sprays of flowers began to be used. As the 16th century advanced this inconspicuous border was first elaborated by the addition of ribbons, masks and similar accessories, and then it was widened to include canopies, figures, animals and birds. By the 17th century the border sometimes comes near to being the dominant feature, with historical and emblematical themes, landscapes, heraldry and drapery, or it is architectonic, with base, supporting columns and entablature, enriched with sculpture. In the 18th century the borders tend, as a general rule, to become narrower again; the imitation of oil-paintings imposed upon the weavers by Oudry and his school led to the representation of moulded and gilt picture-frames as borders. Occasionally there was no border except the plain narrow selvedge, the place of the border being supplied by wood panelling, or other architectural framework

Tapestries were freely displayed indoors and out of doors at coronations, church festivals, pageants and processions, and on all occasions of ceremony. For domestic purposes they were often carried with the movable household goods as the family migrated during the course of the year from one habitation to another, to enliven the walls, or to be hung on tenter hooks left permanently in the rafters of large halls to facilitate convenient division into smaller apartments when occasion required

Flemish weavers early took to wandering abroad to places where special inducements were offered for earning a living, and few countries in Europe where tapestry weaving was carried on were able to claim that they owed nothing to such immigrants. Several arrived in England as early as the 14th century, and a high-warp weaver of Arras was met with even in Hungary by a traveller in 1432.

France.—France is linked closely with Flanders in the beginnings of its tapestry-weaving industry. The associations of the two countries were intimate, both geographically and politically Arras, the most famous tapestry-weaving centre of all, passed from one country to the other in the 15th century Moreover the dukes of Burgundy, who ruled Flanders with such splendour from 1363 to 1477, were members of the royal house of France. High-warp weaving is numbered among the crafts followed in Paris as early as the year 1302, but it is unsafe to assume without question that tapestries ordered or obtained through an agent in Paris were necessarily made there, or even in France.

The known facts concerning the famous tapestries of the Apocalypse in the cathedral of Angers throw light on this problem. The series was begun in the year 1376 for Louis, duke of Anjou, and the panels ultimately passed by bequest to the cathedral of Angers in 1480. The cartoons were prepared by Hennequin de Bruges, and the weaving was started under the supervision of Colin Bataille, citizen, weaver and tapestry-merchant of Paris. Guidance in delineating the scenes was obtained from an illuminated ms. of the Apocalypse in the library of King Charles V. of

BURGUNDIAN TAPESTRY

"Courtiers with Roses," the second of a set of three tapestries probably made about 1435 at the order of Charles VII., whose emblem was the rosebush. It is woven of wool in a coarse texture, flat rep, about 12 ribs to the inch, with strong hatchings which throw figures and flowers into silhouette. The tapestry, which is attributed to the artist Jean Fouquet, is of the best period of French weaving, when Gothic decorative qualities were at their height. Since its exhibition at the Louvre in 1904 it has been considered among the world's most important tapestry specimens. It was purchased in 1909 by the Metropolitan Museum of Art, New York

FRENCH AND GERMAN TAPESTRIES OF THE 15TH CENTURY

1. "The Boar Hunt in the Forest," a 15th century French tapestry attributed to the environs of Paris, one of a series illustrating the pastimes of the aristocracy. Size 9 ft. by 11 feet
2. "The Occupations of the last six months of the year," a German tapestry of the early 15th century woven in coloured wools and linen thread on linen warp. Size 15¼ in. by 8 ft. 11½ inches

TAPESTRY

AN ENGLISH TAPESTRY BY SHELDON

Jacob's dream, one of the series of tapestry cushion-covers by William Sheldon, depicting incidents in the life of Jacob. Sheldon, who flourished during the second half of the 16th century, was the first Englishman to establish a tapestry factory; one was at Weston, one at Barcheston, Warwickshire. Old Testament scenes were favourite subjects with these Warwickshire weavers

France. The ms. (Bibl. nat., Paris, franç. 403) was written at the end of the 12th century, but the scenes were based on an earlier tradition, originating (according to some authorities) as early as the 8th century. The series was added to from time to time until its completion in the 15th century.

The first tapestry factory in France about the origin of which there is definite information was established at Fontainebleau by Francis I. in the year 1535. Its work reflects the Italianate leanings of French art under that monarch. It is supposed that the weavers of Fontainebleau were transferred to the Hôpital de la Trinité at Paris, where tapestry-work was begun under Henry II. Other factories were set up at Paris in the following years, and some outlasted the foundation of the Gobelins factory.

In the provinces, the factory at Aubusson seems to have begun work with the aid of immigrant weavers from Flanders, though at what time is not exactly known. There are records of weaving there from the beginning of the 16th century, but there is no clue to the identification of the tapestries of Aubusson at that time. It is thought possible that the famous tapestries of the "Lady of the Unicorn" from Boussac, now in the Cluny museum at Paris, were woven there. If so, it began well. In the year 1665 the factory at Aubusson was placed under royal patronage, but the standard of craftsmanship there never rivalled that of the royal tapestry factories of Paris, though its work has often shown good decorative qualities. The tapestries of Aubusson at the present day are worthy of the long record of the factory. The tapestry-works of Felletin and Bellegarde were largely auxiliary to those of the neighbouring town of Aubusson, and they followed the same tradition. Tapestries were also woven at Reims, Tours, Nancy and Maincy. "Les amours de Gombaut et de Macée," a rhymed story of peasant life of the end of the 15th century, was reproduced several times in tapestry during the two following centuries. Sets are stated to have been woven at Aubusson, Tours and Paris, as well as at Brussels.

The most renowned of all French tapestry-factories, that of the Gobelins, united several of the Parisian factories existing in 1662, the year in which it was inaugurated by Louis XIV. Weavers of Flemish origin, already employed in Paris, were transferred to the new works. It was the choice of Charles Le Brun, whose decorative instinct was quite remarkable, as director of the works, which enabled the new works to interpret so well the tastes and artistic aspirations of the time. Among the first undertakings was a set of tapestries from Raphael's frescoes in the Stanze of the Vatican, after copies made by the students of the French Academy in Rome, then newly founded. Other sets, among them the famous "Chasses de Maximilien" were copied, in accordance with the fashion of the time, from older Flemish tapestries in the royal *garde-meuble*. Many sets were designed to reflect the luxury and achievements of Louis XIV.—the "Histoire du Roi," his victories, the capture of cities, the royal residences. Under the succeeding kings, decoration was the chief aim, and such subjects as Don Quixote, fortune tellers and children at play were the vehicle of decorative schemes of much refinement. The work of the Gobelins has always been characterized by the excellence of the materials, by the range and high quality of the dyes, and by extraordinary manipulative skill. All the resources of the king and his ministers were freely used to render the factory worthy of the age which brought it into being. The upheaval of the Revolution left the Gobelins undisturbed, and to-day it still enjoys its ancient privileges.

The royal factory at Beauvais was set up about the same time as the Gobelins. Under Philippe Béhagle, a weaver from Tournai, it earned a great reputation. Among the greatest works produced at Beauvais were those from the designs of François Boucher, who was also employed for the Gobelins. At the present time, Beauvais uses only the low-warp loom and the Gobelins the high-warp. These two factories eclipsed all others in France, but a factory at Caen was busy in the latter half of the 17th century, that at Tours continued down to the 18th, and in the first half of that century some good work was done at Nancy.

Italy.—Tapestry weaving in Italy has been carried on, at one place or another, practically without intermission from the 15th century; but in spite of the real beauty of much Italian work, the craft has never become entirely acclimatized in a country where fresco-painting is more suited to the climate and the national genius. At first, tapestry-weavers from the Low Countries and France were induced to migrate to Italy, for the purpose of carrying out special local commissions. Tapestries were thus made in Florence, Siena, Rome, Urbino, Milan, Genoa, Venice, Ferrara, Bologna and elsewhere.

In spite of the artistic activity in Rome and Florence under Pope Leo X. in the earlier years of the 16th century, it is significant that the reproduction of Raphael's cartoons for the Sistine chapel was entrusted to a weaver at Brussels. Other cartoons by Italian artists were sent by the Medici to be woven at Bruges. We also learn, from Vasari, that Leonardo's lost cartoon of the Temptation in the Garden of Eden was to have been copied in Flanders. The Italian historian also mentions two immigrant weavers of the 16th century, Nicholas Karcher and J. B. Rost, who worked at Ferrara. Karcher wove the series of the history of SS. George and Maurelius in Ferrara cathedral, and those of the history of the Virgin and the Old Testament in the cathedral of Como. Both weavers also worked at Florence, where the duke of Tuscany founded a factory which continued until the 18th century.

In Rome, after an attempt in the 15th century, and again in the 17th, to start tapestry-weaving under papal patronage, a factory was inaugurated by Clement XI. in the year 1710 which is still at work under the Government of Italy. Factories were founded in the 18th century at Turin and Naples. Most of the tapestries woven in Italy have been designed by Italian artists.

Spain and Portugal.—In Spain, as in Italy, Flemish weavers were induced to settle when tapestry-work was to be done. After a few scattered efforts, the factory of Santa Isabel at Madrid gained some celebrity in the 17th century; the workroom is seen in Velasquez's picture "Las Hilanderas" in the Prado. In the early years of the 18th century Van der Goten of Antwerp was employed in Madrid. A factory at Seville did not last more than a few years. The most famous of all Spanish tapestries are those woven in the factory of Santa Bárbara at Madrid after the designs of Goya. Altogether this celebrated artist painted 45 subjects, taken from the peasant life of Spain, between the years 1776 and 1791. Thirty-six of these designs and most of the tapestries are still preserved in the Escorial and in the royal residences. There are scattered records of tapestry-weaving in Portugal from the 15th century onwards, but little is known of any work done except that at Tavira in the 18th century.

England.—Tapestries were widely used in England before any regular factory was founded for meeting the needs of the country. The dukes of Burgundy, from the last years of the 14th century onwards, made gifts of many tapestries to members of the English royal family. Well-to-do subjects followed the royal example in their use. One of the most beautiful sets of tapestries of the first half of the 15th century in existence, with hunting scenes, in the possession of the duke of Devonshire, probably came direct from the looms of Tournai or Arras. In the latter part of that century a weaver of Tournai was licensed to import tapestries into England. A little later Cardinal Wolsey's agents in the Low Countries spent large sums on his behalf. In one year alone (1522) 21 sets, numbering 132 pieces altogether, were bought for him. At the death of Henry VIII. the inventory of the royal possessions enumerated over 2,000 tapestries. Yet up to this time no tapestry-factory existed in England, and when at last one was founded it came into being through the initiative of a country squire. There are records of arras-weavers operating in England from time to time before that event, but no factory-tradition was established: and it is even probable that these weavers, immigrants or others, were chiefly engaged in repairs. A tapestry at Winchester college, with the mythical arms of King Arthur of Britain, and large red and white roses, on a "paned" ground in stripes alternately red and blue, belongs to the reign of Henry VII. There are strong arguments tending to show that this panel commemorates the birth of Prince Arthur (so named after the British king), eldest son of Henry VII., at Winchester in the year 1486;

the design is unusual, and as the workmanship does not show the accomplishment of Flemish weaving at the time, the panel may have been woven in England. On the other hand the tapestries made about the year 1511 for William Warham, archbishop of Canterbury, and now at Aix in Provence, are Flemish work.

William Sheldon, to whom the honour is due (as indeed he claims in his will) of having been the first to establish tapestry-weaving in England, set up looms at Barcheston and Baddesley Clinton in Warwickshire not long after the middle of the 16th century. Although his chief weaver, Richard Hyckes, had been sent to the Netherlands to learn the craft, these English tapestries have a character of their own. The tapestries which, above all, have preserved Sheldon's name from unmerited oblivion are the maps of English counties belonging to the Bodleian library at Oxford and the Yorkshire Philosophical Society. Such evidence as can be gleaned about the Barcheston work tends to show that it went on, for a short time at any rate, after the foundation of the factory at Mortlake in the year 1619, though the possibility that it was absorbed into the royal factory should not be lost sight of. The promoters of that factory, in a petition to King James I., instanced the example of the French king, whose factories at Paris had brought him so much honour. Weavers from the Netherlands were engaged, and effective steps were taken to secure a standard of craftsmanship equal to that of any contemporary work. At first, the subjects of older Flemish tapestries were copied, after the fashion of the time, and this procedure was largely followed throughout the career of the factory, which lasted, with varying fortunes, till the end of the century. With its decline, ateliers were set up in the neighbourhood of London by weavers who had been employed at Mortlake, and there can be no doubt that this rivalry hastened the decline of the parent factory, which finally closed its doors in the year 1703. William Benood worked at Lambeth and Francis Poyntz at Hatton Garden, but the most eminent and perhaps the greatest, of all these weavers was John Vanderbank of Great Queen street, Soho, whither the Great Wardrobe was removed from Hatton Garden towards the end of the 17th century. Vanderbank held the office of Yeoman arras-worker in the reigns of William III., Anne and George I. Looms were set up at Chelsea about the year 1723 by James Christopher Le Blon. He wove two or three small panels of the Head of Christ, after the Vatican emerald, but nothing else by him is known. Parisot, a Frenchman, wove small tapestry panels at Paddington and Fulham towards the middle of the 18th century. A few years later, Paul Saunders, a capable and original weaver, was at work in London After his time there is little to be said about tapestry-weaving in England for another 100 years. The revival in the latter part of the 19th century will be referred to later.

Germany and Switzerland.—In its earlier stages, tapestry-weaving in Germany and Switzerland held aloof from the Flemish tradition. Work seems to have been done chiefly in convents and private houses In the border of a tapestry in Bamberg cathedral, two Dominican nuns are seen at work at the loom—no doubt the weavers of the panel itself. Most of these tapestries are small. Long narrow panels, illustrating scriptural subjects, rhymed romances, allegories and fanciful or purely decorative themes were woven in Switzerland, principally in Basel and the neighbourhood, in the 15th and 16th centuries. There is a remarkable collection in the Basel museum. It is not unusual in mediaeval German work to find small details done in knotted pile after the manner of carpet-weaving, and occasionally whole tapestries were woven in pile. An example of the 12th century is in the cathedral of Quedlinburg, and another, of the early years of the 16th, is in the Victoria and Albert Museum.

In the 16th century, factory-work was organized after the example of the Low Countries at Lauingen in Swabia. At the end of the century a factory was started at Munich under Flemish direction. A fresh start was made in the year 1718, and weaving continued for another 80 years. Works were set up at Berlin and Würzburg towards the end of the 17th century, and at Dresden early in the 18th century.

Other Countries.—As in Germany, tapestry-weaving in Scandinavia was a domestic craft in the middle ages, and such it has always continued to be. A few early specimens have been preserved; among them is the panel attributed to the 12th century, with figures symbolical of the months of April and May, from Baldishol church, and now in the Museum at Oslo. They bear witness to the early origin of tapestry-weaving in Scandinavia, and also to its continuity with little change down to recent times. Few colours are used and the designs are extremely simple. The traditional character of much Scandinavian work often renders the age of a specimen a matter of considerable doubt. In Sweden and Norway the weaving of relatively large panels, with subjects taken from the Bible or from the legends of heroes, was carried on down to the later years of the 18th century, to be revived in recent times. Many pieces are squares, often double, for cushion-covers. It is significant that ordinary pattern-weaving for curtains and hangings has been carried on contemporaneously with the work more usually associated with the tapestry-process. In this and other respects Scandinavian work throws light on the practice of tapestry-weaving in primitive times.

In Denmark, Flemish weavers were established before the end of the 16th century. A series of tapestries at Rosenborg castle, Copenhagen, was woven by command of King Christian V. to commemorate events in the war between Sweden and Denmark in the years 1675 to 1679

In Holland, tapestry-weaving was closely associated with Flanders and it followed the same tradition. Weaving was done at Middelburg as early as the 15th century. In the 17th century Delft and Amsterdam were the chief centres.

In Russia, tapestries were woven at Moscow in the early years of the 17th century by a weaver from Antwerp. At Leningrad, weavers from the Gobelins were established under Peter the Great early in the 18th century, and portraits of members of the royal family were woven. Flemish weavers arrived in the latter half of the century, and domestic scenes after the fashion of the Low Countries were woven. Tapestry-weaving was carried on well into the 19th century.

Present Day.—Throughout Europe the spacious dwellings of even half-a-century ago are rapidly being replaced by smaller apartments, for which some slighter form of ornament is regarded as equally appropriate, while it is often less costly. Since the War, the relatively high cost of tapestry-work, and the straitened circumstances of many to whom the weavers would naturally look for employment, has contributed still further to give a temporary setback to the industry.

The great exhibition of modern industrial art held in Paris during the summer of 1925 showed that there is still a healthy vitality from the workers' point of view. Sound work was shown by several European countries. The panels exhibited by the Gobelins and Beauvais factories were unsurpassed in scope, as well as in technical mastery. Indeed they were worthy of a tradition of two centuries during which these factories have been maintained by the State. Themes of national interest were set in hand upon the restoration of peace. The subject of one large panel was the Entry of the Americans into the war, and another was entitled "Verdun and Victory." Furniture-upholstery showed ships, aeroplanes, infantrymen leaving the plough, cannon and military trophies. The Aubusson factories exhibited a panel showing an ironclad steaming into an African port. A panel woven at Felletin, "the Garden of Eden," was a sort of "verdure" in vivid modern colours. These panels can only be regarded as exceptional products of the industry, rendered possible by State subvention or brought about by the special circumstances of a great exhibition.

In Austria tapestry-weaving is taught in the school of arts applied to industry at Vienna, and tapestries woven by pupils were shown at Paris. A remarkable series of panels, entitled allegories of the arts and crafts, has been woven in Czechoslovakia for the palace of the president of the republic. In Scandinavia and Finland panels of a formal and decorative type, mostly of moderate size, continue the tradition of earlier times.

A factory was inaugurated at Heverlé near Louvain in Belgium, with the concurrence of the minister of industry and labour, early

TAPESTRIES: MODERN ENGLISH AND 18TH CENTURY FRENCH

Top: "St. George and the World" (showing the call to battle, the struggle and the victory), the second panel of the Legend of St. George series produced at Merton Abbey as part of the Eton College War Memorial. The designs were by Mrs. Ackers Douglas. Bottom: "The Quarry," a portion of the eighth panel in the series of "The Hunts of Louis XV." executed at the Gobelins factory in 1744 after a design by J. B. Oudry

in the year 1905. Spain and Italy each have a factory still at work with a career of two centuries behind it—that of Santa Bárbara at Madrid and of San Michele at Rome. Tapestry-weaving has also been going on in Florence during recent years.

In England, the factory set up at Windsor in the year 1876 lasted for 10 or 11 years; the weavers were mostly from France, and the French tradition was followed, though contemporary English designs were reproduced. About the same time William Morris started tapestry-weaving at Merton abbey. The aim was to revive the mediaeval tradition, and to bring this effort into association with the movement that gave such distinction to English craftsmanship and literature at the time. Among the subjects of the panels woven there, perhaps the series of the Holy Grail is the most famous. A set of four tapestries of the legend of St. George, part of the war memorial for Eton college, has been completed recently (Plate IX.). These tapestries depart in some degree from the tradition of Merton abbey, recalling Flemish work of the early Renaissance, and involving the preparation of a large number of intermediate tints for the interpretation of the cartoons. Some of the weavers employed on these panels were disabled soldiers who had received their training under a scheme subsidized by the Government at the conclusion of the War. The looms set up early in the year 1892 by William Baumgarten at New York, with the assistance of weavers from Aubusson, inaugurated tapestry-weaving in the United States of America. The result was the installation of a factory at Williamsbridge in the suburbs of the city, where tapestry-weaving is still carried on. In 1911, A. Herter's factory in New York and L. Kleiner's at Edgewater, N.J., were founded.

Tapestry-weaving is more widely spread at the present time than this brief summary would suggest. A good deal of work has been done by private individuals, and in the present state of affairs this practice seems to offer the best hope for its maintenance in the future.

Preservation and Repairing.—The lining, mounting and repairing of tapestries has always been an essential, if subsidiary, branch of the tapestry-weaver's calling. The cost of lining and mounting is mentioned in old accounts. Numbers of the Gobelins tapestries now in the Mobilier National in Paris still have their original linen linings. They are stitched down in diagonal lines running the whole way across from right to left and from left to right, making a large diamond network of lines. Where the warp is horizontal, as in the great majority of cases, this arrangement relieves the strain of the weight of the tapestry upon the weft threads. Tapestries thus strengthened are far less liable to dilapidation, and any damage should be made good without delay by competent persons, or it will rapidly become worse.

In the year 1587 two arras-workers showed a piece of Arras half-cleaned. Well-known weavers in the 17th and 18th centuries, like John Vanderbank, and his successor in the Great Wardrobe, John Ellys, included the lining, mending and cleaning of tapestries in their duties. The skill and experience gained by repairers of old tapestries has been largely responsible for a development giving rise to mixed feelings. Complete panels have been woven from time to time, very skilfully imitating some particular class of old work. Generally these tapestries are relatively small and simple in design. It behoves collectors to be on their guard when considering the purchase of tapestries of a class which lends itself to reproduction.

The "tapestries" woven on the Jacquard power loom since the middle of the 19th century need not be described in detail. Their lifeless uniformity renders them unmistakable, and their cheapness is their only commendable quality. (*See* INTERIOR DECORATION.)

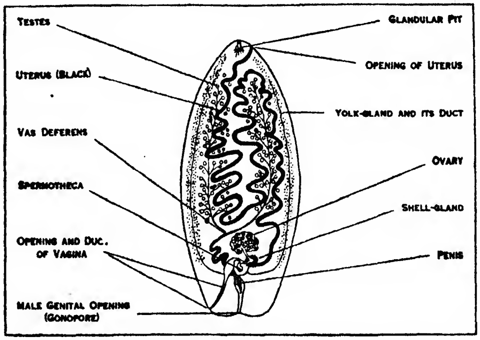
TAPEWORMS (Cestoidea or Cestodes), a class of endoparasitic Platyhelminthes (*q.v.*) in which the body is usually flattened and ribbon-like, and may be unisegmental or composed of a chain (strobila) of "segments" (proglottides). In the latter case the segmentation is not comparable with that of an annelid or arthropod, but is probably to be looked upon as an adaptive device for the multiplication and dissemination of eggs. The number of segments in a complete strobila varies, in different species, from three or four to many hundreds, and the length of the chain from less than a millimetre to several metres. Each segment contains



FROM LANKESTER, "TREATISE ON ZOOLOGY" (BLACK)

FIG. 1.—DIAGRAM ILLUSTRATING THE REPRODUCTIVE SYSTEM OF AMPHILINA FOLIACEA

a separate set of reproductive organs, but the nervous and excretory systems are continuous throughout the chain. Tapeworms have no mouth or alimentary canal, liquid food being presumably taken in by absorption through the body-wall. The adult worms are, with few exceptions, intestinal parasites of vertebrates. In almost all known cases the life-history involves an intermediate host and a somewhat complex metamorphosis.

General Morphology.—The body of the adult is covered externally by a cuticle, below which there is a cellular subcuticular layer. All the internal organs are embedded in loose parenchymatous tissue. In most forms the parenchyma contains numerous "calcareous corpuscles"—small refringent nodules composed mainly of carbonate of lime. The function of these is unknown. Possibly they are merely stored-up excretory products. The musculature consists mainly of longitudinal fibres, often in definite bundles and situated, for the most part, rather deeply in the parenchyma.

In the segmented forms there is, at what is usually called the anterior end, a specialized "head" or scolex, serving as an organ of fixation. This is generally provided with muscular suckers or variously modified sucker-like organs known as bothria or bothridia, and may, in addition, bear a central proboscis-like structure, the rostellum, which is commonly armed with chitinoid hooks. The region nearest to the scolex is the zone of proliferation of new segments, which are, as a rule, continually being formed throughout the life of the worm. As they pass back along the strobila the segments become successively sexually mature and finally gravid, the most posterior usually containing little but a uterus crowded with eggs.

The nervous system consists of an intercrossing system of nerve-fibres and ganglionic cells at the anterior end (in the scolex in strobilate forms), and usually a single pair of main lateral nerve cords which are continuous throughout the body and without segmental ganglia. The excretory or "water-vascular" system is composed typically of two pairs (dorsal and ventral) of main longitudinal canals, continuous throughout the strobila and connected together anteriorly.

The animals are, with rare exceptions, hermaphrodite, each individual, or each segment in strobilate forms, being potentially male and female. The male duct and the vagina may have separate apertures or may open side by side into a common atrium. There is considerable variation in the position of these openings. In unsegmented forms they may be terminal, subterminal or ven-

tral, while in segmented forms they may be on the ventral surface or on one of the lateral margins of the segment. The essential organs of the genital apparatus do not differ greatly from those of other groups of Platyhelminthes. The oviduct connected with the ovary and its associated glands, and with the inner end of the vagina, leads into a uterus in which the fertilized eggs are accumulated.

Classification.—There have been considerable changes during recent years in the systematic arrangement of this group. The older division into unsegmented forms (Monozoa) and segmented forms (Merozoa) has been generally abandoned, since it does not correspond with an arrangement based on internal anatomy In the most recent comprehensive classification (that of Poche) the Cestoidea are primarily divided into two main groups or subclasses, Amphilinoinei and Taenioinei.

The former group contains two families of unsegmented forms, parasitic in fishes.

(1) Amphilinidae These are leaf-shaped or ribbon-shaped forms, with a more or less well developed proboscis-like organ at the "anterior" extremity, and with the openings of the male and female ducts near the "posterior" end The long, tubular uterus has an independent pore near the anterior end These worms inhabit the body-cavity of certain fresh-water fishes.

(2) Gyrocotylidae. These are remarkable forms with frilled margins and with a rosette-like organ at the "posterior" extremity, and having all three genital openings near the "anterior" end The adults inhabit the intestine of certain marine fishes (the Holocephali), and the intermediate hosts appear to be lamellibranch molluscs

The Taenioinei are a large assemblage of forms, including about 30 families. They are divided by Poche into four orders.

I. Bothriocephalidea. This order includes one family of unsegmented forms (the Caryophyllaeidae) and several families of strobilate forms, the most important of which are the Diphyllobothriidae and the Bothriocephalidae In the most typical members of this order the scolex is provided with a pair of longitudinal slit-like bothria, situated dorsally and ventrally, and the genital apertures are on the ventral surface.

II. Echinobothriidea, containing only the family Echinobothriidae, parasitic in elasmobranch fishes.

III. Tetrarhynchidea, containing three families, of which the most typical is the Tentaculariidae (or Tetrarhynchidae). These are forms in which the scolex, in addition to two or four bothria, bears four retractile proboscides armed throughout with hooks or spines. The adults are intestinal parasites of elasmobranch fishes.

IV. Taeniidea This is the largest and most important order, and may be divided into two suborders, Phyllobothriinea and Taeniinea, and some 17 families. The Phyllobothriinea, in the adult stage, are chiefly parasites of cold-blooded, the Taeniinea of warm-blooded vertebrates Of the families contained in the former suborder the best-known are the Phyllobothriidae and Proteocephalidae, while the Taeniinea include several large and important families, such as the Anoplocephalidae, Davaineidae, Dilepididae, Hymenolepididae, and Taeniidae

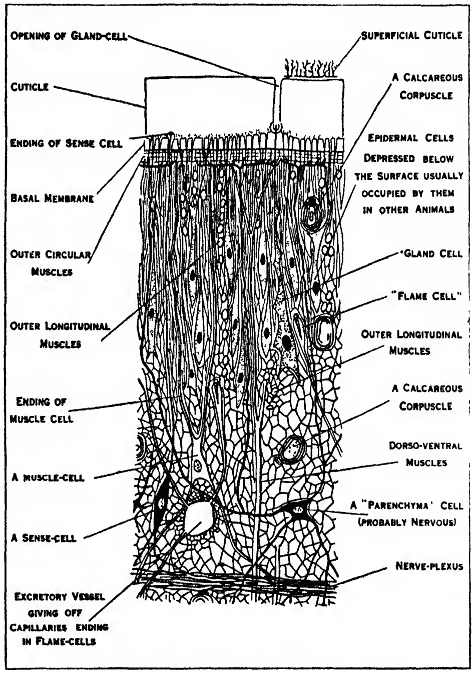
LIFE HISTORY

Development.—The eggs of Cestodes are usually enclosed in two membranes, one of which may show chitinoid thickening, forming a hard "shell." In the Bothriocephalidea the shell is provided with an operculum at one pole, like that of a digenetic Trematode. The embryo, at the stage when it is ready to hatch, is a spherical or oval mass of cells (called an "onchosphere"), provided at one pole with chitinoid hooks, of which in most species there are three pairs—hence the name "hexacanth embryo." In certain Amphilinoinei, however, the embryo has ten hooks. The embryonic hooks are used as levers, chiefly in burrowing among the tissues of the intermediate host.

In some of the Bothriocephalidea the embryo is provided with an external ciliated envelope and hatches in water, where it swims about by means of its cilia. In the human parasite *Diphyllobothrium latum,* for example, the ciliated embryo is at first free in fresh water and is then swallowed by a small Copepod (*Cyclops* or *Diaptomus*). Shedding its ciliated coat, the embryo penetrates into the body-cavity of the Copepod, and develops into a more elongate form called the *procercoid.* If the Copepod is swallowed by a suitable fish, such as a pike, perch or trout, the procercoid develops further among its tissues into a *plerocercoid,* and is then infective for the final host, infection being acquired by eating the fish in a raw or imperfectly cooked state. For the development of this species, therefore, and of others related to it, two successive changes of host are required. The larval forms known as *Sparganum,* which occur in many land vertebrates, including man, have been shown to be the plerocercoids of *Diphyllobothrium.*

The larval forms of Tetrarhynchidea, resembling the scolex of the adult, without the strobila, or with only an unsegmented appendage, occur encysted among the tissues of various marine animals, chiefly teleostean fishes.

Among the best known of the Taeniidea the developmental history is quite different The human parasite *Taenia solium* may be taken as typical. If an egg of this worm be swallowed by the proper intermediate host (in this case the pig) the hexacanth embryo is liberated in the intestine and proceeds to pierce the intestinal wall, wandering about among the tissues and usually coming



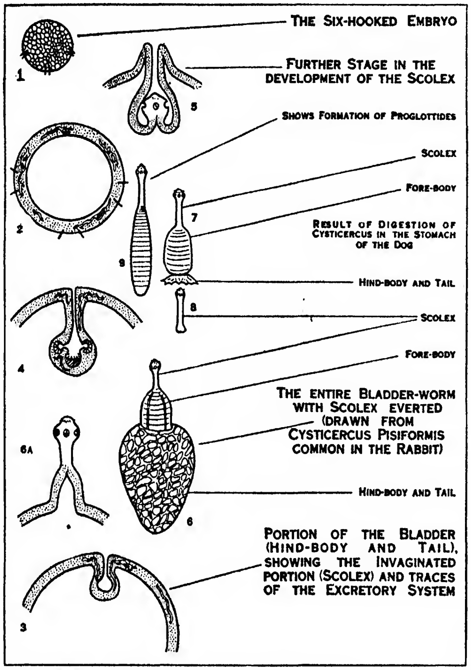
FROM LANKESTER, "TREATISE ON ZOOLOGY" (BLACK)

FIG 2—MICROSCOPIC STRUCTURE OF A TAPEWORM. A PORTION OF A TRANSVERSE SECTION THROUGH THE BODY-WALL OF LIGULA INTESTINALIS

to rest among the muscles. Here it grows into a small bladder, in whose wall a depression or invagination appears on the side opposite to the embryonic hooks. At the bottom of this invagination five thickenings appear, destined to become the four suckers and the median rostellum. Finally the hooks are developed on the rostellum, and the bladder-worm, or *cysticercus,* is fully formed. Should this be ingested by a human being with raw or imperfectly cooked pork, the "head" is evaginated and attaches itself to the lining of the intestine, and the "neck" joining it to the bladder begins to form a series of proglottides. Another human parasite,

Taenia saginata, has a similar development, but is without hooks, and makes use of the ox as intermediate host.

Many modifications occur in the form of the bladder-worm, but the essential features of the development are the same throughout the order. In some forms the original bladder-worm gives rise to several or many scolices instead of the usual single scolex, a phase of asexual multiplication thus being introduced.



FROM LANKESTER, "TREATISE ON ZOOLOGY" (BLACK)

FIG. 3.—DEVELOPMENT OF A TAENIID TAPEWORM (TAENIA PISIFORMIS) 1–5, development of the six-hooked embryo, within the intermediate host, into a bladder-worm, and successive stages in the formation of the head. 6–9, evagination of the head, and further development of the larval form into an adult worm, in the final host

In the gid-parasite of the sheep (*Taenia* or *Multiceps multiceps*) the bladder-worm, which occurs in the brain and is often called a *Coenurus*, gives rise to numerous scolices, each capable of developing into an adult worm if ingested by a dog or other suitable carnivorous host.

In *Echinococcus granulosus* this phase of multiplication is elaborated still further, the original embryo developing in the intermediate host into a large and relatively thin-walled bladder or cyst ("hydatid"), from the inner surface of which there are budded off a large number of "brood-capsules," each containing from 10 to 30 scolices. Daughter cysts may also be budded off, and these may give rise to further scolices, so that altogether a very large number of potential adult worms may be formed from the original embryo. This worm occurs, in the hydatid stage, in the liver and other organs of a large number of hosts, including man, sheep, ox and pig. The adult is a very small worm with only three or four segments, and occurs in the intestine of the dog, wolf and fox.

As may be noted from the examples already given, the intermediate host is usually an animal likely to be devoured by the final host. Thus the dog harbours several Taenioid tapeworms whose intermediate hosts are rabbits and sheep. The cysticercus of *Taenia taeniaeformis* of the cat occurs in rats and mice. A number of species of *Hymenolepis* parasitic, as adults, in ducks and geese make use of small fresh-water Entomostraca such as *Cyclops* and *Cypris* as intermediate hosts. Houseflies and earthworms are the vehicles of infection for several of the tapeworms of fowls. *Dipylidium caninum*, a common parasite of the dog and cat, passes its cysticercus stage in fleas and in the louse, *Trichodectes*. The louse is capable of swallowing the eggs of the worm, but the adult flea cannot do so. Fleas become infected during their larval period, the eggs, when swallowed, hatching in the hinder part of the intestine and the embryo boring through its wall into the body-cavity. Here they do not continue their development until the pupal stage has been passed, the cysticerci becoming fully formed only in the adult flea. Infection is acquired by dogs and cats, and accidentally by man, through swallowing fleas containing them.

The larvae of many of the Phyllobothriinea, whose adult forms are found in the spiral valve region of the intestine of sharks and rays, occur among the tissues of other marine animals. One such larval form (apparently belonging to a species of *Tylocephalum*) occurs in the pearl-oyster, and is believed to be one of the principal causes of the production of pearls. This, apparently, takes place only in the event of the death of the parasite from some unknown cause.

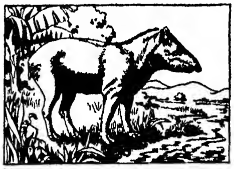
Economic Importance.—From the fact that tapeworms often occur in enormous numbers in the intestine of an apparently perfectly healthy animal, it is clear that they are not always definitely injurious to their hosts. As parasites of man and of domestic animals, however, they have considerable importance. As a rule their ill effects are most manifest in young animals, and they are sometimes responsible for serious digestive and nervous disturbances, and even for severe losses among stock and poultry. The adult worms, besides depriving the host of a certain amount of nutrient material, secrete substances which have been shown to be definitely toxic in many instances, when injected into the blood or body-cavity of experimental animals. The same is true of the larval forms, and certain changes take place in the blood-cells of infested animals which indicate that some of these poisons are normally absorbed into the system. It is probably, however, by the migrations of the larvae within the body, and the secondary invasions by pathogenic organisms for which they prepare the way, that the most serious harm is done. Only in exceptional cases, such as the invasion of the brain by the hydatid of *Echinococcus*, are tapeworms really dangerous to man. (H. A. B.)

TAPIOCA (a native Brazilian word), a farinaceous food substance prepared from cassava starch, the product of the large tuberous roots of the cassava or manioc plant. (*See* CASSAVA.) Cassava starch, separated from the fibrous and nitrogenous constituents of the roots, is spread, while in a moist condition, upon iron plates, and with constant stirring exposed to such heat as causes a partial rupture of the starch granules, which agglomerate into irregular pellets, becoming hard and translucent when cooled. In this condition the starch forms the tapioca of commerce, a light, pleasant and digestible food, much used in puddings and as a thickener for soups.

A BABY TAPIR BEING FED FROM A BOTTLE

TAPIR, the name for large woodland mammals, forming the family *Tapiridae* of the order Perissodactyla (*q.v.*), with five front and three hind toes, massively built and with the nose and upper lip produced to form a short flexible trunk. Four species inhabit South and Central America, and one, *Tapirus indicus*, the Malay region. The latter is the largest, and is readily recognized by its black fore- and hind-quarters and white body. It may stand 3ft. 6in. at the shoulder and is solitary, shy, nocturnal, and inoffensive, frequenting deep forests in the neighbourhood of water. Its diet is exclusively vegetarian. The American species are all nearly uniform dark brown when adult, but the young, like those of *T. indicus*, are spotted and striped with white. The

best-known New World form is *T. terrestris* of Brazil and Paraguay. In habits it and the other three species resemble the Asiatic form The peculiar distribution of the tapirs is explained by the presence of fossil forms in Europe, China and the U.S.A. in Miocene, Pliocene and, in the two latter localities, Pleistocene formations.



THE BRAZILIAN TAPIR (TAPIRUS TERRESTRIS) FOUND ONLY IN CENTRAL AND SOUTH AMERICA

TAPPET is an intermediary fitment which converts the action of a rotary cam or lifter into a linear motion, with a return movement by gravity or spring pressure. The largest tappets are those in the ore stamp batteries, which raise a weight of sometimes as much as a ton The tappets in internal-combustion engines require nice regulation to ensure obtaining the full power of the engine and to maintain silence in the valve operation. (*See* AERO-ENGINES; MOTOR CAR.)

TAPS AND DIES: *see* MACHINE TOOLS.

TAPTI, a river of western India. It rises in Betul district of the Central Provinces, flows between two spurs of the Satpura hills, across the plateau of Khandesh, and thence through the plain of Surat to the sea. It has a total length of 450 m. and drains an area of 30,000 sq.m For the last 32 m. of its course it is a tidal river, but is only navigable by vessels of small tonnage; and the port of Swally at its mouth, famous in Anglo-Portuguese history, is now deserted, owing to silting.

TAPUYAN (GES), a large and important group of tribes of South American Indians, forming an independent linguistic stock. The name Tapuya under which this stock is usually known, is a Tupi (*q.v.*) word, meaning "enemy" or "stranger," and was applied by them to tribes of other affiliations as well The stock has also been called Ges, which being less open to misunderstanding, is in many ways preferable. The area occupied by the Tapuyan (Ges) tribes covered a large part of the highlands of eastern Brazil, extending from the central part of the State of Maranhão south through Goyaz and Bahia to São Paulo and the borders of Matto Grosso. To the west, tribes of this stock are found as far as the Xingu river. At the time of the first European contacts they did not reach eastwards to the Atlantic coast, which was held by a thin strip of intrusive Tupi peoples But at an earlier period Tapuyan tribes probably extended to the shore both in Bahia and Maranhão.

Physically the majority of the Tapuyan tribes appear to belong to the older long-headed stratum of the population The Botocudos (*q.v.*) resemble the prehistoric makers of the shell-heaps or sambaquis of the Brazilian coast, whereas the tribes more in the interior represent the type of the crania from the Lagoa Santa caves. The culture of these tribes was generally extremely simple. They went as a rule entirely without clothing, and wore labrets and large wooden discs as ear-ornaments. They built only temporary shelters of poles and leaves, depended mainly on hunting, fishing and wild jungle products for food and were often cannibalistic. They had no pottery, textiles or canoes, and some tribes were said to be without the dog. The bow and club were their chief weapons. For the most part they lived in small local groups, with very simple social organization. The dead were buried in shallow graves, and not interred in burial urns as among the Tupian tribes. Very little is known of their religious beliefs or practices, and in general these tribes have been but superficially studied

TAR: *see* NAVAL STORES; COAL TAR; CAMPHORS; WOOD FINISHES; GAS MANUFACTURE

TARA, THOMAS PRESTON, 1ST VISCOUNT (1585–1655), British soldier, who distinguished himself in the defence of Louvain in 1635, and was in the same Irish regiment in the Spanish service as his rival Owen Roe O'Neill. Preston, who was appointed general of Leinster, took a prominent part in the war of factions that raged intermittently in Ireland from 1642 to 1652. In 1650 Charles II. while in exile created him Viscount Tara; and after his departure from Ireland in 1652 he offered his services to Charles in Paris, where he died in October 1655. His wife was a Flemish lady of rank, by whom he had several children, one of his daughters being the second wife of Sir Phelim O'Neill.

TARA, a village of co. Meath, Ireland. It is celebrated for the Hill of Tara, which was for many centuries a royal residence and the scene of great meetings of the people. The isolated hill, upon which five highroads converged, is about 510 ft. in height. On it are six raths or circular earthworks, the largest of which, the king's rath (*rath-na-riogh*), encloses other works, including the *forradh* or meeting-place, a flat-topped mound. On this (but not in its original position) stands a pillar stone, said to be the stone of destiny on which the Irish kings were crowned. An oblong enclosure, 759 ft. in length by 46 ft. in breadth, formed of earthworks, with entrances at intervals on each side, represents the banqueting hall. In the middle of the 3rd century A.D. King Cormac Mac Art is said to have founded here schools of military science, law and literature In the time of St. Patrick Tara was a great centre of pre-Christian religious rites, and about 560 it was abandoned as a royal residence Here the Danes were defeated in 980; here also, in 1798, a severe defeat was suffered by the insurgents, and in 1843 the hill of Tara was the scene of one of Daniel O'Connell's mass meetings in support of the repeal of the legislative union (Aug. 15)

TARAHUMARE, an Indian nation of Uto-Aztecan family, Piman division, in the Sierra Madre in southern Chihuahua and Sonora, Mexico. They number 30,000 Partly converted to Christianity in the 17th century, they preserve much of their ancient religion, including a cult of the peyote, a drug-containing cactus They farm, but live scattered, are docile in disposition, and still weave cloth, use the bow and arrow, and poison fish in streams They are remarkable distance runners Much in their habits and beliefs recalls the Pueblos of the American South-west

TARAI (*i.e.*, "moist land"), the name of the submontane strip of marshy jungle stretching beneath the lower ranges of the Himalaya in northern India This strip may be said to extend roughly from the Jumna river on the west to the Brahmaputra on the east, and a large portion of it lies within Nepal The term, however, is now officially confined to a subdivision of Naini Tal district in the United Provinces At its northern edge, where the waterless forest tract of the Bhabar ends, a series of springs burst from the surface, and these, increasing and uniting in their progress, form the numerous streams that intersect the Tarai The Deoha is the great river of the Tarai proper, and is navigable at Pilibhit. Elephants, tigers, bears, leopards and other wild animals are found Everywhere it is most unhealthy, and inhabited only by tribes who seem proof against malaria, though large tracts are now being reclaimed for cultivation and settled with agriculturists from the plains.

TARANCHI. The Taranchi or Ili-Tatars, numbering about 100,000, are a branch of the Iranian Turks, and live in Semirechie and in Transcaspia, whither they migrated when Kulja passed under Chinese rule. They are closely related to the Sarts in religion, culture and language, differing from them principally in allowing their women more freedom.

TARANTELLA, Italian dance of a rapid whirling character, popularly believed to be a cure for the supposed poisonous sting of the Tarantula spider, whence it would appear to be natural to derive its name. In point of fact, however, this is to be referred, not to the tarantula, but to the place Taranto, in Apulia, which gave its name also to the curious disease known as tarantism. This was an hysterical malady prevalent in the region in question in earlier centuries, one of the characteristic features of which was a tendency to dance, which at the same time served as the best means of working it out of the system. Hence, therefore, the real origin of the name, its popular and mythical association with the tarantula having arisen later.

TARANTO (anc. *Tarentum, q.v.*), a seaport of Apulia, Italy, and the capital of a province 50 m. from Lecce W. by N. by road, and 68 m by rail (44 m W. by S. from Brindisi). Pop.

(1921) 51,292 (town) 103,687 (commune). The city proper is situated on a rocky island 56 ft. above sea-level, which, in ancient times was a peninsula, the isthmus on the west having been cut through by Ferdinand I. of Aragon. This island separates the Gulf of Taranto (Mar Grande) from the deep inlet of the Mar Piccolo, and is sheltered by two other flat islands, San Pietro and San Paolo. This rock is the site of the citadel of the ancient town; its population is confined within small houses and narrow streets. The Strada Garibaldi along the Mar Piccolo is inhabited by fishermen whose language retains traces of Greek. The cathedral, dedicated to San Cataldo, an Irish bishop, has externally some remains of Saracenic Gothic; internally it has been completely modernized (retaining however 16 ancient columns in the nave) and the shrine of the patron saint has been termed "an orgy of rococo" (1657). It has a crypt of the 6th or 7th century. There is a museum in the former convent of San Pasquale, with an especially fine collection of vases, terra cottas, and silverware, jewellery, Greek statuary, mosaics, etc., from Taranto and other sites in Apulia. Adjacent is the Palazzo degli Uffizi, containing various public offices. To the east, across the swing bridge over the channel connecting the Mar Grande with the Mar Piccolo is the new part of the town, on the site of the main part of the ancient city, extending as far as the Arsenal and even beyond: while the Boyo, with the railway station, lies to the west of the island. Here too is the unimportant commercial harbour. The chief industry is the cultivation of oysters in the Mar Piccolo; besides oysters Taranto carries on a large trade in *cozze*, a species of large black mussel, which is packed in barrels, with a special sauce. Excellent fish abound in the Mar Piccolo, ninety-three different species being found. The ebb and flow of the tide is distinctly visible here, Taranto being one of the few places in the Mediterranean where it is perceptible. In 1861 the strategic importance of Taranto was recognized, and the arsenal is the most important in Italy after Spezia. It extends for a mile and a half along the southern coast of the Mar Piccolo, which constitutes its chief basin. The receiving-dock and the anchorage for torpedo boats, with its wide landing-stage, form dependencies: and the Mar Piccolo provides a well-sheltered anchorage, 36 ft. deep and 6,325 acres in extent. There is also a large private shipbuilding yard, a brewery, a flourmill, oilmills, etc.

In 927 Taranto was entirely destroyed by the Saracens, but rebuilt (though henceforth restricted to the island) in 967 by Nicephorus Phocas, to whom is due the construction of the bridge over the channel to the north-west of the town, and of the aqueduct which passes over it. The town was taken by Robert Guiscard in 1063. His son Bohemund became prince of the Terra d'Otranto, with his capital here. After his death Roger II. of Sicily gave it to his son William the Bad. In 1301 Philip, the son of Charles II. of Anjou, became prince of Taranto. The musician Giovanni Paisiello (1741–1816) was born here. The castle, originally Byzantine, dates in its present form from 1480 and 1577. The tarantula (*see* below), inhabits the neighbourhood of Taranto. The wild dance, called *tarantella* (*q.v.*), was supposed, by causing perspiration, to drive out the poison of the bite. (T. A.)

TARANTULA, strictly speaking, a large spider (*Lycosa tarantula*), which takes its name from the town of Taranto (Tarentum) in Apulia, near which it occurs and where it was formerly believed to be the cause of the malady known as "tarantism." This spider belongs to the family Lycosidae, and has numerous allies in various parts of the world. The tarantula, like all its allies, spins no web as a snare but catches its prey by speed of foot. It lives on dry, well-drained ground, and digs a deep burrow lined with silk to prevent its falling in. In the winter it covers the orifice with silk, and hibernates in a dormant condition. It also guards its cocoon and young in the burrow. It lives for several years. The sexes are approximately the same size but do not surpass ¾in. in length of body. Like all spiders, the tarantula possesses poison glands in its jaws, but a particle of the secretion of these glands is not more virulent than that of other spiders of the same size.

Tarantula is often applied indiscriminately to many large spiders not related to *Lycosa tarantula;* and to at least one Arachnid belonging to a distinct order, *Galeodes luscasii* of the Egyptian desert. In English-speaking parts of the American continent, the Aviculariidae, or "bird-eating" spiders, much larger and more venomous than any Lycosidae, are called tarantulas.

TARAPACÁ, a northern province of Chile, bounded N. by Tacna, E. by Bolivia, S. by Antofagasta, and W. by the Pacific. Area 16,386 sq. miles. Pop. (1920) 100,553. It is part of the rainless desert region of the Pacific coast of South America, and is absolutely without water except at the base of the Andes where streams flow down into the sands and are lost. In some of these places there is vegetation and water enough to support small settlements. The wealth of Tarapacá is in its immense deposits of nitrate of soda (found on the Pampa de Tamarugal, a broad desert plateau between the coast range and the Andes, which has an elevation of about 3,000 ft.). The mining and preparation of nitrate of soda for export maintain a large population and engage an immense amount of capital. Silver is mined in the vicinity of Iquique, the capital. The ports of the province are Pisagua, Iquique and Patillos, from which "nitrate railways" run inland to the deposits. Tarapacá was ceded to Chile by Peru after the war of 1879–83, and was organized as a province in 1884.

TARARE, a town of east-central France, in the department of Rhône, on the Turdine, 28 m. W.N.W. of Lyons by rail. Pop. (1926) 11,206. It is the centre of a region engaged in the production of muslins, tarletans, embroidery and silk-plush, and in printing, bleaching and other subsidiary processes. The manufacture of muslins was introduced from Switzerland in 1756. The manufacture of Swiss cotton yarns and crochet embroideries was introduced at the end of the 18th century; at the beginning of the 19th figured stuffs, open-works and zephyrs were first produced. The manufacture of silk-plush for hats and machine-made velvets was set up towards the end of the 19th century.

TARASCA, the native people of the State of Michoacan, west of Mexico city and valley; of distinctive language. They beat off Aztec attempts to conquer them, and remained independent under a national overlord residing at Tzintzuntzán, on Lake Pázcuaro. Their culture was the generic one of southern Mexico, but simpler than that of the Aztecs or Mayas, and pottery vases and figures from the Tarascan area show persistence of Archaic traits. Neither their archaeology, ethnology, nor language has been systematically explored by modern methods.

See N. Leon, *Los Tarascos* (1904); E. Seler, *Gesammelte Abhandlungen*, iii. (1908).

TARASCON, a town of south-eastern France, in the department of Bouches-du-Rhone, 62 m. N.W. of Marseilles by rail. Pop. (1926) 5,058. Tarascon stands on the left bank of the Rhône opposite Beaucaire, with which it is connected by a railway bridge and a suspension bridge. The church of St. Martha, built in 1187–97 on the ruins of a Roman temple and rebuilt in 1379–1449, has a Gothic spire and interesting tombs in the crypt. Of the original building there remain a porch and a side portal flanked by marble columns with capitals like those of St. Trophimus at Arles. The former leads to the crypt, where are the tombs of St. Martha (1658), Jean de Gossa, governor of Provence under King René, and Louis II., king of Provence. The castle, built on a rock, was begun by Count Louis II. in the 14th century and finished by King René in the 15th. It contains a turret stair and a chapel entrance, both 15th-century, and fine wooden ceilings. The building is now used as a prison. The hôtel-de-ville dates from the 17th century. The civil court of the arrondissement of Arles is situated at Tarascon, which also possesses a commercial court, and fine cavalry barracks. The so-called Arles sausages are made here, and there is trade in fruit and early vegetables. In *Tartarin de Tarascon* Alphonse Daudet has satirized the provincial life of Tarascon, which has a tribunal of commerce and the fair of Beaucaire. It formerly had the two fêtes of La Tarasque, the latter in celebration of St. Martha's deliverance of the town from a legendary monster of that name. King René presided in 1469, and grand exhibitions of costume and strange ceremonies take place during the two days of the festival. Tarascon was originally a settlement of the Massaliots, built on an island of the Rhône. The mediaeval castle, where

Pope Urban II. lived in 1096, was built on the ruins of a Roman camp. Tarascon preserved the municipal institutions granted it by the Romans, and of the absolute power claimed by the counts of Provence only recognized the rights of sovereignty.

TARASP-SCHULS, a Swiss railway station in the lower Engadine, giving its name to a group of villages of which Schuls, the capital of the lower Engadine, situated about 160 ft. above the Inn river, is the chief. Tarasp is famed for its springs, which have been known since the middle ages, but it lies low in the valley and many visitors live at Vulpera, above the south bank of the Inn river. Above the village of Tarasp is the early mediaeval castle of that name, heavily restored as in 17th century style in recent years. The neighbourhood is famed for its beauty.

TARAXACUM, the botanical name for the common dandelion (*q.v.*).

TARBELL, EDMUND C. (1862–), American artist, was born at West Groton, Mass., on April 26, 1862. He was a pupil of the schools of the Boston Museum of Fine Arts and of Boulanger and Lefebvre, Paris, and became a distinguished painter of the landscape, of the figure, and of portrait. He won the gold medal of the National Academy of Design in 1908, the bronze, silver and gold medals of the Carnegie International exhibition at Pittsburgh, Pa., and various other important prizes and medals He is represented in the museums of many American cities. In 1906 he was elected a National Academician, besides being a member of the Ten American Painters. He was instructor of painting in the Boston Museum of Fine Arts, and was later principal of the Corcoran School of Art, Washington, D.C., and chairman of the council of the school of the Museum of Fine Arts, Boston, Massachusetts.

See F. W. Coburn, "Edmund C. Tarbell," *International Studio,* vol. xxxii, p 75–77 (1907); and J. E. D. Trask, "About Tarbell," *Amer. Mag. of Art,* vol. ix., p. 217–228 (1918).

TARBERT, fishing village at the head of East Loch Tarbert, an arm of the sea on the west shore of the mouth of Loch Fyne, Argyllshire, Scotland. Pop. (1921) 1,705. The harbour, though it has a narrow entrance, is absolutely safe and can shelter the whole Loch Fyne fishing fleet The pier for the passenger steamers that call here is about ¼ m. from the village The herring fishery—including a large trade in curing—forms the only industry. Overlooking the harbour are the ruins of a castle built by Robert Bruce in 1326. The isthmus connecting the districts of Knapdale and Kintyre is little more than one mile wide, and boats used once to be dragged across to the head of West Loch Tarbert, a narrow sea loch nearly ten miles long.

TARBES, a town of south-western France, capital of the department of Hautes-Pyrénées, 98 m. W.S.W. of Toulouse on the Southern railway. Pop. (1926) 26,745. Under the Roman dominion *Turba,* which was about 11 m. S E of the present town of Tarbes, was the capital of the Bigerriones, one of the states of Novempopulania. The bishopric of Tarbes dates from the 5th century, and in feudal times its bishops held the chief temporal authority, that of the counts of Bigorre, of which Tarbes was capital, being limited to the quarter of the town where their castle was built. The English held the town from 1360 to 1406. In 1569–70 Tarbes was twice taken by Gabriel, count of Montgomery, and the inhabitants driven out, but in August 1570 the peace of St. Germain allowed them to return Subsequently Tarbes was several times taken and re-taken, and a number of the inhabitants of Bigorre were forced to take refuge in Spain, but in 1594 the members of the League were finally expelled. The English, under Wellington, gained a victory over the French near Tarbes in 1814. Tarbes stands in a fertile plain, stretching to the Pyrenees, on the left bank of the Adour, streams from which are conducted through the town. The lines of the Southern railway from Morcenx to Bagnères-de-Bigorre and Lourdes and from Toulouse to Bayonne cross here. Chief among the many open spaces is the Jardin Massey (35 acres), given to his native town by a director of the gardens of Versailles and containing a museum of paintings and antiquities. Near a small lake stands a cloister (15th century) brought from the abbey of St. Sever-de-Rustan, 14 m. N E. of Tarbes The architecture of the cathedral, Notre Dame de la Sède, is heavy, but the cupola of the transept (14th century), and a rose window of the 13th century, in the north transept, are interesting. There is also a modernized Carmelite church of the 13th century. Tarbes is the seat of a bishopric under the archbishop of Auch, of a prefecture, tribunals of first instance and of commerce, a chamber of commerce and a board of trade-arbitrators. Tarbes has an important stud for the breeding of Anglo-Arabian horses, much used by light cavalry. The industrial establishments include tanneries, potteries, saw-mills and turners' shops. There are important fairs and markets.

TARBUSH, the close-fitting, flat-topped and brimless cap, in shape like a truncated cone, made of felt or cloth, worn by Mohammedan men throughout the East either as separate head-gear or forming the inner part of the turban. It used to be worn as the badge of a Turkish subject in Turkey and Egypt, where it was red in colour with a black or blue silk tassel. It is the same as the "fez." In September 1928, Turkish citizens were forbidden to wear the fez, under severe penalties, by President Kemal Pasha.

TARDE, GABRIEL (1843–1904), French sociologist. He was professor of modern philosophy at the Collège de France, Paris, and an official of the ministry of justice For a bibliography of his many important works *see* M M. Davis, *Psychological Interpretations of Society* (1909). His *Psychologie économique* (1902) was translated into English as *Social Laws.*

TARDIEU, ANDRÉ PIERRE GABRIEL AMÉDÉE (1876–), French politician and writer, was born in Paris on Sept. 22, 1876. Educated at the École Normale Supérieure, he was *chef de cabinet* to Waldeck-Rousseau from 1899 to 1902. From 1902 to 1914 he lectured at the École des Sciences Politiques and the École Supérieure de la Guerre, and was foreign news editor on *Le Temps.* Entering the chamber of deputies in 1914 he acted as special commissioner in the United States (1917–18), member of the Peace Conference (1918–19), and minister of the liberated regions (1919–20). As captain of Chasseurs between 1914 and 1916, he was wounded and three times mentioned in despatches. At the Peace Conference (1919) he had a considerable share in drafting the political and territorial clauses. He presided over the Committee of Five which drafted the Allied Reply to the German Observations on the draft terms of the Peace Treaty. Tardieu also presided over the Alsace-Lorraine Committee, the Committee of the Saar and that of the execution of the treaty.

Tardieu's political attitude was characterized by his inflexible attachment to the policy of Clemenceau, with whom he was associated in the closest collaboration for war and for peace. Three times in succession, between 1919 and 1924, he refused to enter the Government, in order to maintain his independent defence of this policy As director of the *Echo National,* the daily paper founded by Clemenceau and himself, he waged a fierce war, in foreign affairs, against the successive revisions of the Treaty of Versailles; and in internal affairs, against the steps which paved the way for the victory of the *cartel des gauches.* Between 1924 and 1926 he had no seat in the Chamber, but in Feb. 1926 he was elected once more, and in July joined the Poincaré cabinet as minister of public works and of the liberated regions.

Tardieu was the author of the following historical works: *Questions Diplomatiques* (1905); *France and the Alliances* (1908); *La conférence d'Algésiras* (1909); *Le Prince de Bulow* (1909); *Fürst v. Bulow* (1910); *La France et les alliances* (1910); *Le mystère d'Agadir* (1912); *Notes sur les Etats-Unis* (1917); *L'Amérique en armes* (1919); *La Paix* (1921); *Le Slesvig et la Paix* (1925).

TARDIGRADA, a class of animals probably belonging to the Arthropoda and sometimes referred to the Arachnida (*q.v.*), but without good reason. The Bear-animalcules, as these animals were formerly called, are all of small size, the largest being not much over 1 mm. in length, while most of them are very much smaller. They are not parasitic but are found in very variable habitats, in damp moss, on flowering plants, in sand, fresh water and even in the sea; and in adaptation to this wide range of external conditions a very large number of genera and species have been evolved.

The organism consists of a well developed head-region in front and of a short body composed of four fused segments, each represented externally by a pair of short, stout, unjointed limbs gener-

ally terminated by sharp claws, which seem to range in number from four to nine, but sometimes, as in *Batillipes*, ending in three pairs of racquet-shaped, digitiform outgrowths. The limbs of the last pair project backwards from the posterior end of the body on each side of the anus. The cuticle, which is not chitinised, may be smooth or sculptured in various ways and is sometimes strengthened with segmentally arranged plates (*Echiniscus*) and sometimes provided with long paired hair-like cirri.

No special organs of circulation or respiration are known. The alimentary canal traverses the body from end to end. Within the mouth is a pair of protrusible stylets, large glands open into the oesophagus, there is a muscular pharynx and large median and lateral glands open into the intestine posteriorly. The nervous system, which is remarkably well-developed, consists of a bilobed cerebral ganglion, frequently provided with a pair of eye-spots, and of a ventral chain of five large ganglia connected by lateral commissures. The sexes are not distinct and the generative products are discharged either into the posterior end of the alimentary canal or directly to the exterior through a median pore in front of the anus. The eggs are large and in some cases at least are enclosed, when laid, in the cuticle of the parent which is cast to form a case for them. The young when hatched are about one-third the size of the parent which they closely resemble apart from the occasional absence of one pair of limbs which is subsequently developed.

The Tardigrada are divided into two orders:—(1) The Eutardigrada (*Macrobiotus, Hypsibius, Milnesium*) in which the head is without cirri, the legs are not telescopically retractile and the four claws of each foot are coalesced to form a single pair of branched claws; and (2) the Heterotardigrada (*Echiniscus, Batillipes*, etc.) in which the head is provided anteriorly with two pairs of cirri, and on each side with one long cirrus and a shorter spatulate process, the *clava*, the legs are to a varying extent telescopically retractile and the claws are not coalesced.

The Tardigrada cannot be assigned with complete confidence to the Arthropoda, or Gnathopoda, until it be proved that their oral stylets are modified appendages. Assuming that they belong to the Arthropoda, they must rank as a class by themselves. They have been generally relegated to the Arachnida on the supposition of their kinship with the Acari, but their internal and external anatomy make such an affiliation unlikely. They have also been compared to *Peripatus* mainly on account of the structure of their limbs; but there seem to be no good reasons for regarding the two types as related. (R. I. P.)

TARDIVEAU, RENÉ: *see* Boylesbe, René.

TARENTUM, a Greek city of southern Italy (Gr. Τάρας), (mod. Taranto, *q.v.*), situated on the north coast of the gulf of the same name, on a rocky peninsula at the entrance to the only secure harbour in it. The entrance was defended by the two islands called the Choerades (now S. Pietro and S. Paolo). It was a Spartan colony, founded by Phalanthus about 708 B.C. (*See* Sparta.) Taras was a mythical hero, son of Neptune. Situated in a fertile district, especially famous for olives and sheep, with an admirable harbour, great fisheries and prosperous manufactures of wool, purple and pottery, Tarentum grew in power and wealth and extended its domain inland. A great defeat by the natives in 473 B.C., led to a change of government from aristocracy to democracy. A feud with the Thurians about the district of the Siris was settled in 432 by the joint foundation of Heraclea.

In the 4th century Tarentum was the first city of Magna Graecia, and its wealth and artistic culture at this time are amply attested by its coins. (*See* Numismatics.) In the second half of the century Tarentum was in constant war with the Lucanians, and did not hold its ground without the aid of Spartan and Epirote *condottieri*. Then followed war with Rome (281), the expedition of Pyrrhus, whom Tarentum summoned to its aid, and at length, in 272, the surrender of the city by its Epirote garrison. Tarentum retained nominal liberty as an ally of Rome. In the Second Punic War it went over to Hannibal in 212, and suffered severely when it was retaken and plundered by Fabius (209), who sold thirty thousand citizens as slaves. It revived after receiving a colony in 123 B.C., which received the name of Neptunia. In the time of Augustus it was essentially Greek and a favourite place of resort (Horace, *Od.*, iii. 5, 53). Belisarius ordered it to be re-fortified, but it was soon taken by Totila, who made it his treasure store. After his defeat by Narses, it was sold to the Byzantine Empire by its Gothic governor.

One of the most interesting discoveries of recent years has been that of a *terramara* on the so-called Scoglio del Tonno on the north-west of the town, which in its type and in the character of the objects found there, is exactly identical with the *terremare* of the Po valley. It seems, however, to be an isolated colony, and not to prove a parallel development in north and south Italy. The only relic of any building of the Greek city is a part of a Doric temple on the island—two fluted columns, with a lower diameter of 6½ ft., and a height of 28 ft., and some fragments of the entablature, belonging probably to the beginning of the 6th century B.C. The rock occupied by the modern town was the citadel, but was connected with the land to the west by an isthmus, which was only cut through by Ferdinand I. of Aragon. The line of the walls which defended the city on the east (land) side has been traced, and a few remains of well-cut blocks, with Greek masons' marks, have been found. In the centre of the Agora was the huge bronze Zeus by Lysippus, and facing on to it the Ποικιλή, or painted portico, with pictorial representations of the life of Phalanthus, and the foundation of the city, and the museum. There was also a fine gymnasium and other buildings mentioned by classical writers. Strabo's description of the site (vi. 3, 1) is a good one. The Roman amphitheatre, on the other hand, and remains of Roman baths by the seashore, have been found; the former perhaps occupies the site of the ancient theatre, in which the Roman ambassador was received in 281 B.C. Tarentum was the birthplace of Archytas and Aristoxenes (*qq.v.*).

TARENTUM, a borough of Allegheny county, Pennsylvania, U.S.A., 17 m. N.E. of Pittsburgh, on the Allegheny river and the Pennsylvania railroad. Pop. (1920) 8,925 (82% native white). It has large industrial plants and there are several coal mines in the vicinity. Natural gas is used. Plate glass, glass bottles, table glass, steel tubing, brick and paper are leading products. Tarentum was settled in 1796, laid out in 1829 and incorporated as a borough in 1842. The first glass factory was established in 1872.

TÂRGOVIȘTEA, the capital of the department of Dimbovita, Rumania; situated at the foot of the Carpathians, on the right bank of the river Jalomita, 48 m. N.N.W. of Bucharest. Pop. (1928) 16,800. A branch line connects Târgoviștea with the main Walachian system, and is prolonged northwards into the hills, where there are rich deposits of petroleum, salt and lignite. Coal is also found but not worked. Apart from the scanty ruins of a 14th-century palace, the most interesting building in the town is the Metropolitan church, still one of the finest in the country, with its nine towers and monuments of the princely house of Cantacuzino. It was founded in 1515 by Neagoe Basarab, builder of the famous cathedral of Curtea de Argeș. Târgoviștea is a garrison town, with a cavalry training school and an artillery depot and repairing arsenal.

Târgoviștea was the capital of Walachia from 1383–1698. In the 15th century it was sacked by the Szeklers. Michael the Brave defeated the Turks under its walls in 1597. In the 16th century it had a population of 60,000 and contained 70 churches and 40 convents. Its importance and population decreased when the capital was moved to Bucharest.

TARGU JIU, a large garrison town and capital of the department of Gorj, Rumania; situated among the lower slopes of the Carpathians, on the left bank of the river Jiu, and at the terminus of a branch railway which joins the main Walachian line between Turnu Severin and Craiova. Pop. (1928) 20,000. The town has a considerable trade in timber, petroleum and farm produce. Anthracite coal is found in the neighbourhood. In the neighbouring hills are the monasteries of Tismana, Lairnici and Polovraci, much frequented as summer resorts.

TARGUM. The Targums are the Aramaic translations—or rather paraphrases—of the books of the Old Testament, and, in their earliest form, date from the time when Aramaic superseded Hebrew as the *spoken* language of the Jews. (*See* Hebrew

Language.) In their origin they were designed to meet the needs of the unlearned among the people who had ceased to understand the Hebrew of the Old Testament. In the absence of any precise evidence on the point it is impossible to give more than a rough estimate as to the period at which Hebrew, as a spoken language, was finally displaced by Aramaic. It is, however, certain that the latter language was firmly established in Palestine in the 1st century A.D. By that time, as we know from many sources, Aramaic was not only the language in common use, but had also received official recognition despite the fact that Hebrew still remained the learned and sacred tongue. Hence we may reasonably infer that the mass of the people had adopted Aramaic at a considerably earlier period, probably, as early as the 2nd century B.C., and that the need of Aramaic translations of the sacred text made itself felt but little later.

The Talmudic tradition, however, is, doubtless, correct in connecting the origin of Targums with the custom of reading sections from the Law at the weekly services in the synagogues, since the need for a translation into the vernacular must first have arisen on such occasions. As we know from the New Testament, the custom of reading in the synagogues both from the Law (Acts xv. 21) and from the Prophets (Luke iv. 16 f; Acts xiii 14, 27) was well established in the 1st century A.D.: its introduction, therefore, will date from a much earlier period. The practice of accompanying these readings with a translation into Aramaic is, further, so generally recognized by the 2nd century A.D. that the Mishna takes it for granted, and merely inculcates certain regulations to be observed by the *Meturgemān* (translator), who had by this time acquired a definite status. From it we learn that the *Meturgemān*, who was distinct from the reader, translated each verse of the Law into Aramaic as soon as it had been read in Hebrew: in the readings from "the Prophets" three verses might be read at a time.

Judging by the contents of our existing Targums, and the Targumic renderings given in Jewish literature, it is improbable that any definite system of interpretation was ever formally adopted, the rendering into the vernacular being left to the discretion of the individual *Meturgemān*. At first, no doubt, the translator endeavoured to reproduce the original as closely as possible, but, inasmuch as his object was to give an intelligible rendering, a merely literal rendering would soon be found to be insufficient, and he would be forced, especially in the more difficult passages, to take a more elastic view of his obligations. To prevent misconception he must expand and explain what was obscure, adjust the incidents of the past to the ideas of later times, emphasize the moral lessons to be learned from the national history, and, finally, adapt the rules and regulations of the Old Covenant to the conditions and requirements of his own age. As time went on the practice of introducing additional matter of an edifying character grew in popular favour, and was gradually extended. Thus, by degrees, the reproduction of the original text became of secondary importance, and merely served as a pretext for the discussion of topics that had little or no bearing on the context. The method, by which the text was thus utilized as a vehicle for conveying homiletic discourses, traditional sayings, legends and allegories, is abundantly illustrated by the Palestinian and later Targums, as opposed to the more sober translations of Onkelos and the Targum to the Prophets.

It would, however, be incorrect to suppose that the translation of the text was left entirely to the individual taste of the translator. The latter is rather to be regarded as the representative of the age in which he lived, and his interpretation is to be taken as reflecting the exegesis of that period. That there were certain limits beyond which the translator might not venture, without incurring the censure of the authorities, may be inferred from the few instances of translation which are mentioned with disapproval in the Mishna and elsewhere. A definite rule for guidance in translating is apparently preserved in the *Tosefta* where it is stated that "he who translates quite literally is a liar, while he who adds anything is a blasphemer."

There can be little doubt that the Targums existed for a long time in oral form. They belonged to the class of traditional literature which it was forbidden to write down, and, so long at least as the Targum tradition remained active, there would be little temptation to commit it to writing. But it is highly probable that this prohibition, in the case of the Targums, was mainly enforced with respect to those parts of the Old Testament which were read in the synagogal services, *e.g.*, the Law and the Prophets, and that it was less rigidly observed in regard to the other portions of Scripture: a written translation of the latter would be of special value for the purpose of private study. Hence there is no need to reject the tradition as to the existence of a written Targum on Job in the time of Gamaliel I. (1st century A.D.), especially as references to Targum mss. occur in the Mishna and elsewhere. But, as Dalman has pointed out, it was not these manuscripts, but the living tradition of the learned which was recognized as authoritative throughout the period which closes with the compilation of the Talmud. . . . The official recognition of a written Targum, and therefore the final fixing of its text, belongs to the post-Talmudic period, and is not to be placed earlier than the 5th century.

I. Targums on the Pentateuch.—(1) The so-called Targum of Onkelos admittedly owes its name to a mistaken reference in the Babylonian Talmud. In its original context, that of the Jerusalem Talmud, the passage refers to the Greek translation of Aquila. With the exception of this one reference, the Targum is always introduced in the Babylonian Talmud by the phrase "as we translate" or "our Targum": it is probable, therefore, that the name of the author, or authors, was unknown to the Babylonian Jews. It is first quoted under the title of the Targum of Onkelos by Gaon Sar Shalom (d. A.D. 859). On the linguistic side we may regard Onkelos "as a faithful representative of a Targum which had its rise in Judaea, the old seat of Palestinian literary activity." (*Grammatik des judisch-palästinischen Aramäisch*, p. 12 f.) It is to be regarded as an official translation of the Law, in the Judaean dialect, which was carried out in Babylon, probably about the 4th century A.D.: in its final form it cannot be earlier than the 5th century. The translation, as a whole, is good, and adheres very closely to the Hebrew text, which has not been without its influence on the Aramaic idiom.

Of all the extant Targums that of Onkelos affords perhaps the most characteristic and consistent example of the exegetical methods employed in these works. Two principles may be said to have guided the translators. On the one hand, they had, as their primary object, to produce a faithful rendering of the original which at the same time would be intelligible to the people: for this purpose a purely literal translation would be insufficient. On the other hand, they regarded it as necessary to present the sacred text in such a manner as best to convey the particular form of interpretation then current. But later Jewish exegesis was especially concerned to eliminate everything in the sacred writings that might give rise to misconception with respect to God on the part of the unlearned. Hence we find various expedients adopted in the Targums for avoiding any reference to the Deity which might be misunderstood by the people, or which involved apparent irreverence. Examples of this peculiarly Targumic method are: (1) the insertion of "word," "glory," "presence" before the divine name, when God is referred to in his dealings with men; (2) the insertion of the preposition "before" when God is the object of any action; (3) the use of the passive for the active voice; (4) the use of periphrasis for the more pronounced anthropomorphisms, such as "to smell," "to taste"; (5) the use of different expressions, or the insertion of a preposition before the divine name, when God is compared to man, or the same action is predicated of God and man; (6) the use of יי for יהוה and אלהים and the rendering דחלא or טעוא when אלהים denotes heathen gods. Instances of this endeavour to maintain, as it were, a respectful distance in speaking of God occur on every page of the Targums, but cases also occur, by no means infrequently, where human actions and passions are ascribed to God.

(2) In addition to the Targum of Onkelos two other Targums to the Pentateuch are cited by Jewish authorities, under the titles of the *Targum Jerushalmi* and the Targum of Jonathan ben Uzziel. Of these the former contains only portions of the Penta-

teuch and is therefore usually designated the Fragmentary (Jerusalem) Targum. Its fragmentary character arises from the fact that it is simply a collection of *variae lectiones* and additions to the version of Onkelos, intended possibly for use at public services.

The second Jerusalem Targum admittedly owes its ascription to Jonathan ben Uzziel to the incorrect solution of the abbreviated form by which it was frequently cited, viz., ת״י or *Targum Jerushalmi.* This Targum represents a later and more successful attempt to correct and supplement the Targum of Onkelos by the aid of variants derived from another source. It is not, however, a revision of the Fragmentary Targum—for it is clearly independent of that version—but is rather a parallel, if somewhat later, production, in which the text of Onkelos is already combined with a number of variants and additions. It exhibits, to a marked degree, that tendency to expand the text by additions of every kind, which has been already noted as characteristic of the later stages of Targumic composition. Homilies, legends, traditional sayings and explanations, in fact every form of Haggadic expansion are utilized by the Targumist, so that at times his works convey the impression more of a late *Midrash* than of a translation.

In regard to the source of the two Palestinian Targums to the Pentateuch, we must accept the conclusion of Bassfreund (*M.G.W.J.* xl.) that they both derived their variants from a complete *Targum Jerushalmi.* But though the existence of an older *Targum Jerushalmi* cannot be denied it cannot be of an early date, for many of the latest elements in the Fragmentary and pseudo-Jonathan Targums were undoubtedly derived from their common source. Moreover, the existence of a written Palestinian Targum at an early date is expressly excluded by the evidence at our disposal. In the middle of the 2nd century A.D. R. Simon ben Gamaliel forbade the translation of the Pentateuch in any language but Greek; and this command was upheld by R. Johanan in the 3rd century. Even in the time of the later Amoraim there is no mention of a written Palestinian Targum, though the official Babylonian Targum is repeatedly referred to in the Babylonian Talmud, in the Midrashim, and at times also by Palestinian Amoraim.

Yet it is impossible to hold that the Targum of Onkelos was the only representative of Targum tradition that existed among the Jews down to the 7th century A.D., the period to which the internal evidence compels us to assign the *Targum Jerushalmi* as used by the Fragmentary Targum and the pseudo-Jonathan. We must rather assume that a tolerably fixed Targum tradition existed in Palestine from quite early times. The language employed in the Targum of Onkelos is, admittedly, Palestinian or Judaean, and we may conjecture that the current Judaean exegesis, which, in part at least, must go back to the 2nd century A.D., was not without its influence on the Babylonian translation. This old Targum tradition, however, never received official recognition in Palestine, and was unable, therefore, to hold its own when the new Babylonian version was introduced. We may infer that, as time went on, a reaction in favour of the older renderings made itself felt, with the result that these were collected in the form of variants and appended to Onkelos. But the authority enjoyed by the latter rendered it secure against any encroachments; hence any later expansions, especially those of a popular Haggadic character, naturally found their way into the less stereotyped *Targum Jerushalmi.*

II. Targums on the Prophets.—The official Targum on the Prophets is stated by the Babylonian Talmud to have been "said" by Jonathan ben Uzziel, the disciple of Hillel, and is usually known, therefore, as the *Targum Jonathan.* Elsewhere in the Talmud, however, the quotations from this Targum are given under the name of Joseph bar Chijah, head of the school at Pumbadita in the 4th century A.D. Both in language and style it closely resembles the Targum of Onkelos, and appears to have been modelled on that translation: in certain passages, indeed, it appears to have made use of it. Probably, like Onkelos, it did not assume its final form in Babylon before the 5th century A.D. It naturally follows from the character of the original that the rendering of this Targum is less literal than that of Onkelos, especially in the prophetic books, but, when due allowance is made for the difficulty of the Hebrew, it may be described on the whole as a faithful reproduction of the original text. Its peculiarities of rendering are due to the same principles which were noted as underlying the translation of the Pentateuch. Anthropomorphisms, as a rule, are avoided by means of the same expedients as those employed by Onkelos, expressions derogatory to the dignity of God, or of the heroes of the nation, are softened down, while figurative language is either boldly transposed, or its character clearly shown by the introduction of the particle "as" or "like." There is, further, a tendency to narrow down the scope of the prophetic utterances, and to limit their application to Israel and its immediate enemies. Lastly, in the obscurer passages the Haggadic method of interpretation is employed to its fullest extent, while the translation throughout shows a marked tendency to explanatory additions.

Of a *Targum Jerushalmi* to the Prophets but little is known, though it is hardly doubtful that such a Targum existed, if only in oral form. Traces of this version have been discovered by Bacher in the variants attached to the margin of the *Codex Reuchlinianus,* and printed by Lagarde in his edition of *Prophetae Chaldaice* (1872). The quotations in *'Arūk* from Kings, Ezekiel, Proverbs and Lamentations point to the existence of a *Targum Jerushalmi* to those books.

III. Targums to the Hagiographa.—These Targums possess but little interest for the student of Jewish literature as they are almost entirely the work of individuals, made in imitation of the older Targums.

(1) *Targums to the Psalms and Job.*—These Targums present certain features in common and may therefore be treated under the same heading. Like all the later Targums they exhibit a large amount of explanatory addition, chiefly Haggadic in character. At the same time the translation of the original is not neglected; and, when separated from the later accretions, this is found to follow the Hebrew tolerably closely. Peculiar to these Targums are the double translations, which they give to many verses, one of which is usually Haggadic in character, while the other is more literal. They cannot be earlier than the 7th century A.D., and possibly are of a considerably later date.

(2) *The Targum to the Proverbs* stands apart owing to the peculiarity of the language in which it is written. The influence of the Peshitta version is so clearly marked, that Dalman describes it as a Jewish revision of that version. But setting aside the Syriasms due to the use of the Peshitta, the Targum shows affinity to the Targums to the Psalms and Job. The translation is literal and almost entirely free from Haggadic additions.

(3) *The Targums to the Megilloth.*—The chief characteristic of these Targums is their exaggerated use of paraphrase. They mark the final stage in the development of Haggadic interpretation, in which the translation of the text has practically disappeared in a mass of fantastic and irrelevant matter. The Targum of Esther is known to us in three recensions (1) that of the Antwerp Polyglot, almost a literal translation; (2) that of the London Polyglot, which gives practically the same text with many additions of a Haggadic character; (3) the so-called second (*shēni*) Targum, a much larger work, containing a collection of later *Midrashim* to this book. According to Zunz this "second" Targum is quoted by Rashi (to Deut. iii. 4) as a Jerusalem Targum, and also (I Kings x. 19) as the "Haggada" of the Megilloth Esther. The Targum to Canticles is of a similar character to that of the "second" Esther. Dalman assigns these Targums to a date halfway between the Babylonian Targums (Onkelos and that to the Prophets) and the Jerusalem Targums to the Pentateuch and those to the greater Hagiographa. The British Museum possesses three important Yemen manuscripts for the five Megilloth and the "second" Esther Targum in mss. Or. 1302, 1476 and 2375.

(4) *The Targum to the Chronicles* was first edited from an Erfurt manuscript by M. F. Beck, 1680–1683. A more complete and accurate edition from a Cambridge manuscript was edited by D. Wilkins in 1715. In the translation, which at times is fairly literal, use appears to have been made of the Jerusalem Targums

to the Pentateuch, and of the Targums to the books of Samuel and Kings. The text represented by the Erfurt manuscript is assigned to the 8th, that of the Cambridge manuscript to the 9th century A D

No Targums have so far been discovered to Daniel and Ezra and Nehemiah (J. F. S)

See bibliog on p. 39 of W. O. E. Oesterley and G. H Box, *Short-Survey of Lit. of . . . Judaism* (1920). *See* also P. Churgin, *Targum Jonathan* (Yale, 1927).

TÂRGU-MUREŞ, a town of Transylvania, Rumania, capital of the department of Mureş, 79 m. E of Cluj by rail. Pop. (1928), 23,500. It is situated on the left bank of the Mureş, and is a well-built town, once the capital of the territory of the Szeklers. On a hill dominating the town stands the old fortress, which contains a beautiful church in Gothic style built about 1446, where in 1571 the diet was held which proclaimed the equality of the Unitarian Church with the Roman Catholic, the Lutheran and Calvinistic Churches. The Teleki palace contains the Teleki collections, which include a library of 70,000 volumes and several valuable manuscripts (*e.g.*, the Teleki Codex), a collection of old Hungarian poems, and a manuscript of Tacitus, besides a collection of antiquities and another of minerals. Târgu-Mureş has also an interesting Szekler industrial museum. The trade is chiefly in timber, grain, wine, tobacco, fruit and other products of the neighbourhood. There are manufactures of sugar, spirits and beer.

TÂRGU-NEAMŢU, a town in the department of Neamtu, Rumania, situated among the lower slopes of the Carpathians, and on the left bank of the Neamtu, an affluent of the Moldova. Pop (1928) 10,500, about half being Jews A branch railway runs to Jassy. Nearby is the ruined fortress of Neamtu, constructed early in the 13th century by the Teutonic Knights against the Cumans (*q v*), and the monastery of Neamtu, founded in the 14th century, and containing two churches and many ancient and interesting relics Before the secularization of the monastic lands in 1864, it was one of the richest and most important of the Rumanian monasteries. Baltateşti, 10 m. W by S. of Neamtu, is locally famous for its mineral springs and baths.

TARGU OCNA, a town of Rumania, on the left bank of the river Trotoş, an affluent of the Sereth, and on a branch railway which crosses the Ghimeş pass into Transylvania. Pop (1928) 10,500. Targu Ocna is built among the Carpathian mountains, on bare hills formed of rock salt Outside the town stands the largest prison in Rumania; beyond this are the mines, worked, since 1870, by convicts, who receive a small wage. The estimated total of the salt deposits is 264,000,000 tons, about 11,000 being extracted annually.

TARIFA, a seaport of Spain, in the province of Cadiz, at the extreme south point of the Peninsula, 21 m by rail W S.W. of Gibraltar. Pop. (1920) 11,957. Tarifa is the *Iulia Ioza* of Strabo, between Gades and Belon According to that writer, it was colonized by Romans and the removed inhabitants of Zelis in Mauretania Tingitana. The *Iulia Transducta* or *Traducta* of coins and of Ptolemy appears to be the same place. Its present name, dating from early in the 8th century, is derived from Tarif. (*See* CALIPHATE and SPAIN: *History*) In 1292 Tarifa was taken by Sancho IV. of Castile from the Moors. In the defence of Tarifa Alphonso XI. gained the battle of Salado, a short distance to the westward, in 1340. In 1812 a French force under Victor and Laval vainly endeavoured to capture Tarifa, then held by General Gough.

The town is nearly quadrangular, with narrow, crooked streets, and is still surrounded by its old Moorish walls. The rocky island in front of the town, connected with the mainland by a causeway, is fortified.

TARIFFS are lists of articles with their import or export duties noted. The term is also used for the laws regulating the duties and, in a number of countries, for any price schedules

The United States.—The tariff history of the United States, like that of European countries, divides itself into two great periods, before and after the year 1860. The period before 1860 may again be divided into three sub-periods, the first extending from 1789 to 1816, the second from 1816 to about 1846, the third from 1846 to 1860.

I. (*a*) The Tariff Act of 1789 was the first legislative measure passed by the United States. The Protectionists have pointed to it as showing the disposition of the first Congress to adopt at once a policy of protection; the free traders have pointed to it similarly as showing a predilection for their policy Each has some ground for the claim. The duties of the act of 1789 were very moderate, and, as compared with those which the United States has had under any subsequent legislation, may be described as free trade duties. On the other hand, the spirit of the act of 1789 was protective. Such in the main remained the situation until 1816, duties being indeed raised from time to time in order to secure more revenue, but the spirit and the general rate of the duties not being sensibly modified.

(*b*) After the close of the War of 1812, however, a new spirit and a new policy developed. A demand arose for two closely connected measures: protection to domestic manufactures and internal improvements. Protection was demanded as a means both of aiding young industries and of fostering a home market for agricultural products; it was a part of the "American system." Some movement in the direction of lighter duties was manifested as early as 1816 Still greater changes were made in 1824, 1828 and 1832. The tariff of 1828 was affected by some political manipulation, which caused it to contain objectionable provisions, and to be dubbed "the tariff of abominations." The so-called abominations were removed in 1832, when the protective system was deliberately and carefully rearranged. By this time, however, the opposition to it in the South had reached a pitch so intense that concessions had to be made. The nullification movement led in 1833 to the well-known compromise, by which the rates of duty as established by the act of 1832 were to be gradually reduced, reaching in 1842 a general level of 20% But the reductions of duty made under it proved ephemeral In 1842, when the final 20% rate was to have gone into effect, the protectionists again had control of Congress, and after a brief period of two months, during which this 20% rate was in force, passed the Tariff Act of 1842, which once more restored the protective system in a form not much less extreme than that of 1832

(*c*) Four years later, however, 1846, a very considerable change was secured by the South, and a new era was entered on. The Democratic party now was in control of legislation, and in the Tariff Act of 1846 established a system of moderate and purely *ad valorem* duties, in which the protected articles were subjected, as a rule, to a rate of 30%, in some cases to rates of 25 and 20%. The system, often spoken of as one of free trade, was in reality only one of moderated protection. In 1857 duties were still further reduced, the rate on most protected commodities going down to 24%.

II The second great period in the tariff history of the United States opens with the Civil War. In the session of 1860–61, immediately preceding the outbreak of the conflict, the Morrill Tariff Act was passed by the Republican party, then in control because the defection of Southern members of Congress had already begun. The advances then made were of little importance as compared with the far-reaching increases of duty during the Civil War. Duties were steadily raised, partly by way of off-set to the internal taxes, partly to get additional revenue and largely because of a disposition to protect domestic industries. The close of the war thus left the United States with a complicated system of very high taxes both on imported and on domestic products.

The main features of the tariff history of the United States in the years after the Civil War were that the internal taxes were almost entirely swept away and the import duties on purely revenue articles similarly abolished, while those import duties that operated to protect domestic industries were maintained, and in many cases increased. Efforts were indeed made to reduce the tariff duties, but met with strong opposition, and in the end were almost completely frustrated. The decade immediately following the war brought about the gradual transformation of the high taxes levied on all commodities for revenue purposes into a

system of high duties almost wholly on protected commodities. This transformation met with much opposition, not less in the Republican party than in the Democratic party. The opposition led to a general revision in 1883, which, on the whole, served rather to put things in order than to make any change of policy.

The tariff system as revised and codified in 1883 would probably have remained unchanged for many years had it not been for an unexpected turn taken by political and financial history. In the second half of the decade 1880–90, a continuous large surplus in the Treasury directed attention to the state of the revenue, and gave strength to the protests against excessive taxation. In addition, the Democratic party, which had long been committed, though in a half-hearted way, against the policy of high protection, was brought to a vigorous and uncompromising attack on it through the leadership of President Cleveland. In his presidential message of Dec. 1887 he attacked the system in unqualified terms. The Republicans, as is almost inevitable under a party system, championed the policy opposed by the other side, and declared themselves in favour of the consistent and unqualified further application of protection. The protective question thus became the main issue in the presidential election of 1888, which resulted in the defeat of the Democrats. In the next ensuing session of Congress, the Republicans passed the McKinley Tariff Act. It advanced duties materially on a considerable number of commodities, both raw materials and manufactured articles. A further step towards consolidating the protective system was taken by abolishing the duty on sugar, mainly a revenue duty. For consistency in maintaining the protective principle a direct bounty was given to the domestic producers of sugar in Louisiana. Another turn in the political wheel brought an abrupt change four years later, in 1894. President Cleveland, defeated four years before, was now again elected, and the Democratic party came into power, pledged to change the tariff system. Accordingly the tariff act of 1894 was passed, known as the Wilson Tariff, bringing about considerable reductions of duty. The measure, however, was less incisive than its chief sponsors had planned, because of the narrow majority commanded by the Democrats in the Senate. The most radical change was that the duty on wool, typical among the duties on raw materials, was completely abolished, and with this came a great reduction in the duties upon woollen goods. A duty was reimposed on sugar, chiefly as a means of securing needed revenue, but at a less rate than had existed before 1890; the bounty of 1890 was abolished. The next election in 1896 brought still another turn, the Republicans being once more brought into power under the leadership of President McKinley. At the extra session which President McKinley called in 1897, almost the sole measure considered was the tariff act, known as the Dingley Act. This reimposed the duties upon wool, on most qualities at the precise rates of 1890, on some qualities at even higher rates. Necessarily the duties on woollens were correspondingly raised, and here again made even higher than they had been in 1890. The tariff act of 1909, amending that of 1897, did not appreciably change the situation. It made certain reductions in duties, such as the rates on hides, wool tops and various iron and steel products; but except in the case of hides, the reductions were in most cases more nominal than real. The net result was to leave the general height of the tariff at much the same level as had previously ruled. At the next presidential election in 1912 the Democrats, for the first time since 1892–4, gained control of both the executive and legislative branches of the Government. Immediately the Democratic leaders began the revision of the tariff law. In the act of 1913 most raw materials, including raw wool, were placed upon the free list; the complicated schedules that had grown up in the Republican tariffs were largely scrapped; and the effective protection upon semi-manufactured and wholly manufactured articles was markedly decreased. Sugar was to be admitted free. But the abolition of the sugar duty was not to take effect till 1917; by that time the great war had set in; and under the war conditions, the duty was retained, though at a lower rate than that of 1909.

The act of 1913, however, proved to be of little practical significance. The outbreak of the World War in 1914 made impossible all competition from abroad with United States industries. This situation endured for a year or two after the close of the war, and it was not until the collapse of 1920–21 that serious consideration was again given to the tariff problem. By that time the Republicans were again in power, and were so firmly entrenched, after their decisive victory at the polls in 1920, that they did not hesitate to restore the protection of pre-war days and even increase it. The agricultural regions of the Central West were hardest hit by the great decline in prices, and clamoured for some remedy. The Republicans followed their traditional policy of holding forth a high tariff as the remedy for all ills, and at once enacted the Emergency Tariff Act of 1921, which provisionally reimposed the duty on wool, and raised those on sugar, wheat, corn, meat. In 1922 a general revision was made, and a new complete tariff act was passed. The duties on agricultural products were still further increased, and those on manufactured goods, such as woollens, cottons, silks, pottery, hardware, were either put at the level of the tariff act of 1909 (the last preceding high tariff act) or raised above that level. Some articles previously admitted at low rates were now subjected to high ones, such as dyestuffs and chemicals. All in all, the protective policy was carried higher than ever before. At the same time a new administrative policy was introduced, by giving the tariff commission certain powers as regards modification and adjustment of duties.

Great Britain.—England emerged from the mercantilist policies of the 17th and 18th centuries with a tariff system that not only imposed high rates but was extraordinarily complicated and confused. The first steps toward the radical change which was to come in the 19th century were taken by Pitt. In 1787 he caused the Consolidation Act to be passed, which codified the previous intricate mass of scattered, inconsistent and cumulative duties. In 1786 he also arranged a commercial treaty with France providing for substantial reciprocal reductions of duties; but this measure, unlike that for consolidation, was swept away by the French Revolution. After 1815 English tariff history is marked by two great changes: on the one hand the modification and finally the repeal of the corn laws; on the other, the steady succession of acts which gradually cut down the duties on all other goods and led eventually to the complete adoption of free trade. The corn laws, it is true, were first strengthened; then experiments were made with sliding scale duties, designed to keep the price of corn stable; and finally they were suddenly wiped out at the time of the Irish famine of 1846. They had political support because of the predominance of the gentry and the landed interests in both houses of parliament. But industrially as well as politically they were vulnerable, and inevitably collapsed in a crisis like that of the famine. The other series of events began with Huskisson's measures of 1824, which reduced duties, especially on raw materials such as wool, and went on with a succession of measures until the last remnant of protection disappeared in 1860. The notable steps were Peel's act of 1842, an important and far reaching measure; Peel's second important act, in 1846, contemporaneous with the corn law repeal; Gladstone's famous budget of 1853; and finally in 1860 the removal of the silk duties, the last of the protective duties which had been retained. This final step of 1860 was taken in connection with the Cobden-Chevalier treaty with France, noted below. For half a century thereafter, England was on a free trade basis and was the stronghold of free trade. The system was suited to her industrial development during the period, enabling her manufactures to develop at an extraordinary rate, while foodstuffs and raw materials were imported in ever increasing volume. The system seemed entrenched beyond attack, and this notwithstanding the fact that the landed interest was hard hit by the decline in agricultural prices from 1873 to the close of the century. It was not until the World War of 1914–18 that a change took place, and it then took place to an extent which could not have been expected and, indeed, was not expected when the initial steps were taken. Very shortly after the outbreak of the war in 1915 certain duties were imposed upon luxuries, the so-called McKenna duties; being at the rate of 33⅓% on watches, pleasure motors, cinema films and the

like. Immediately after the war some further changes were made in the same direction, yet still susceptible of interpretation on other grounds than that of a return to protection pure and simple. In 1919 imperial preference to the colonial products, long urged by the colonies themselves, was granted on tea, coffee, cocoa, sugar, the most important being the preference on sugar. In 1920, again, the imports of dyestuffs and coal-tar dyes were completely prohibited, this being in the nature of a war measure, designed to ensure the domestic production of military explosives, and also that of dyestuffs whose importance to textile industries was deemed cardinal. In 1921 came the Safeguarding of Industries Act, which went a step further, imposing a duty of 33⅓% on the product of the so-called key industries, such as optical instruments, barometers, wireless apparatus In the same year came the anti-dumping act, imposing a 33⅓% duty on goods sold in England below cost or sold at particularly low prices because of depreciated currency elsewhere. Some of these duties were repealed by the Macdonald Labour government in 1924. But all were re-enacted in 1925; and then at last the Baldwin government took steps which clearly were not explicable on political or military grounds, or as means for meeting special emergencies. In 1925 not only were the McKenna duties restored, but, what was more important, the safeguarding of industries provisions were given a wide scope. In advocacy of them, most was said about the desirability of preventing unemployment through the protection of established industries. The board of trade was made a sort of tariff commission which should investigate particular cases and recommend to parliament advances in duties; not merely for key industries or because of special circumstances, but as part of a general industrial policy. While the import duties to which this measure led were not, as compared with the entire volume of Britain's trade, of great substantive consequence, they marked unmistakably a departure from the principles of the free trade régime as it existed before 1914

France.—The tariff history of France during the 19th century, like that of England, is divided into two parts, one running to the year 1860, and the other beginning after 1860. France emerged from the revolutionary wars with a cumbrous system, resting partly upon the highly complicated measures left over from the mercantilism of the 18th century, and for a part upon complete prohibition of importation (directed primarily against England) which had been adopted during the war period and was left in force, largely through inertia, for almost half a century thereafter. The tariff system of France, in other words, from 1815 until 1860, was rigidly protectionist. In 1860 the Cobden-Chevalier treaty made an abrupt change, to which the Emperor Napoleon III. was led in some part by intellectual conviction, but much more by the desire to get on good terms with Great Britain. The treaty provided for great reductions on manufactured goods imported from England, while England in her turn not only conceded the free admission of silks, but also reduced duties on French wines. After 1860 France virtually universalized these lower duties, extending them by a series of commercial treaties to almost all the countries of the Continent. These treaties commonly contained the most-favoured-nation clause, and were in turn fortified by treaties which the various countries concluded between themselves as well as with France. The result was an interlacing network of commercial engagements which covered almost the whole of Europe, and brought about not indeed a system of free trade, but one of nearer approach to free trade than had ever before been widely practised. Such, at all events, was the situation for two decades from 1860. The French people, however, had always been restive under the treaty system imposed upon them by the will of Napoleon III. The English treaty, which was terminable after the lapse of ten years, was at first renewed with reluctance, and finally terminated for good in 1891. The protectionist revival culminating in the great Méline Act of 1892. By that France established a double system: maximum duties which were not to be exceeded, and specified minimum duties which the government might concede to other countries in return for concessions supposed to be equivalent. The maximum duties, however, were in no case to be reduced on agricultural products; for in France, as in England, agricultural producers were hard hit by the decline in prices. One important purpose of the act was to deprive the ministry of discretionary power as regards reductions through commercial negotiation; the minimum duties which might be conceded to other countries were specified by the legislature. The system was maintained in essentials, though not without some modification, until the outbreak of the war in 1914. The revival of high protection in France did not run its course without serious difficulties, especially in the way of controversy on rates with other countries. There was a tariff war with Italy in 1888–90 and one in 1892–95 with Switzerland. In 1910 there was again a revision upward, which, however, left the general system intact.

One further factor in French tariff policy during this period was the Treaty of Frankfurt (1871) terminating the war of 1870–71. By that treaty France and Germany had guaranteed each other most-favoured-nation treatment,—not complete, but almost complete, in that they guaranteed to each other the same rates as they conceded to the important neighbouring countries of central Europe. Being incorporated in the general treaty, these provisions, unlike the special commercial treaty of 1860 with England, could not be denounced; and they were felt by both countries to hamper their commercial negotiations, being the more unwelcome because of the constantly growing national antagonism. When all treaties and engagements with Germany, and practically those with other countries also, were swept away with the World War, France was able to proceed untrammelled with a new course of policy. It rested upon the maintenance of a high protective system, susceptible of some liberalization through special bargains with other countries, by which these were to be induced to admit French goods at lowered rates in exchange for specified concessions in the French duties, varying from country to country. In 1920 the maximum and minimum system was virtually given up and the government given free hand in commercial negotiations. The result was a highly complicated series of engagements, which brought into vivid contrast two essentially different lines of policy: that of special bargaining, and that of equal treatment under a most-favoured-nation clause. The second policy was unpopular in France, partly because of its association with the Treaty of Frankfurt, but partly for other reasons connected with peculiarities of French foreign trade. Not only as regards France, but as regards Europe at large, the alignment was marked by one or the other of these two ways of procedure. Those in favour of closer commercial relations preferred the most-favoured-nation method, while high protectionists looked to the policy of specific bargainings. On the whole France was not successful in securing what she wished by bargaining, even though she had political advantages in dealing with States like Czechoslovakia, Hungary, Yugoslavia, and even Belgium. In 1927 she was compelled to arrange with Germany a treaty virtually upon most-favoured-nation basis, a change which marked a halt in the other policy, and perhaps the beginning of a general trend the other way.

Germany.—The tariff history of Germany, like that of German history in general, is closely connected with Prussia. Prussia took the lead in the creation of the German customs union (*Zollverein*). She arranged a partial union in 1819 which was followed by the *Zollverein* of 1834, including practically the whole of the later Empire. Prussia was then a grain exporting country, and favoured a liberal tariff system. As time went on, manufacturing industries developed, especially in the west and south of Germany, and contests arose within the *Zollverein* between the free trade and protectionist parties. In these, upon the whole, the anti-protectionists were victorious until after the establishment of the Empire. A commercial treaty with France in 1862, a sequel of the Anglo-French treaty of 1860, confirmed the liberal tendency. But after 1871 Germany, like France, and at about the same time, turned the other way. Under Bismarck's lead, and in consequence of an alliance between the industrialists of the west and south and the agricultural interests of the east (now threatened by imports), Germany returned in 1879 to protection. Grain duties were imposed, and proved an important source of revenue, because imports continued on a large scale; at the same time the continuing imports made the landed interest firmly protectionist.

At the beginning of 1892 Germany entered upon a policy of commercial treaties which were based upon special negotiation with each particular country; though they were prevented by the treaty of Frankfurt from having as much effect in the way of discriminations between countries as might otherwise have been the case. This policy of specialization was continued in the legislation of 1902, when rates were further increased and further commercial treaties were initiated. As in the case of France, the policy of specialized commercial negotiations led to quarrels and retaliations, there being tariff wars with Russia, Spain and Canada. After the World War, Germany for a while was restricted by certain provisions of the Versailles Treaty. These required her for five years from the date of the treaty (that is, during 1919–24) to give most-favoured-nation treatment to the Allies, while at the same time leaving the Allies free. With the termination of this arrangement in 1924 Germany proceeded more freely, and in 1925 adopted a new tariff. A protectionist régime was established both for agricultural products and for manufactured goods, with an expectation, however, that the duties might be reduced through bargaining for lower duties by other countries on German goods. Success in this direction was achieved in 1927 by the commercial treaty with France, which provided for certain reductions upon French goods, and also secured for German goods imported into France treatment virtually on a most-favoured-nation basis. Treaties with other countries contained similar provisions, and emphasized the acceptance by Germany of the most-favoured-nation policy and of a general disposition to moderate the protectionist régime.

Other Countries.—The same trend in tariff legislation appeared in other countries during the years succeeding 1860. In almost all, the protectionist movement gathered strength again after 1880. Austria, Russia, Italy turned to high tariffs, sometimes mitigated by commercial agreements, sometimes aggravated by the failure of commercial negotiations. The greatest extreme was reached in Russia, which under the leadership of Witte developed a system of protection more extreme than that of any other country, not excepting the United States. After the World War, when the financial and treaty arrangements had all to be remodelled, there was the same resurgence and accentuation of protective tariffs. The main cause lay in the strengthening of national feeling and in the persistence of nationalist antagonisms engendered by the war. The new States which arose after the war or were greatly enlarged by it, such as Poland, Czechoslovakia, Yugoslavia, Greece, Rumania, turned to protective measures. In good part they were influenced by imitation of the larger powers and not least by imitation of the United States. The glamour of the prosperity of the United States led easily to an imitation of American policy in all respects. A system of high protectionism, which in the United States was comparatively harmless, threatened to have serious evil consequences on the Continent.

Tariff Commissions.—A new administrative policy in reference to tariff matters came into existence in various countries after the World War, by which considerable powers were given to other than legislative bodies in the determination of rates. The United States in the Tariff Act of 1922 gave certain powers or duties to the U.S. tariff commission, which had been established in 1916. Under the so-called flexible provisions of the act of 1922, the commission was empowered to investigate the cost of production of goods in the United States and in foreign countries, and to ascertain what rates of duty would equalize competition between domestic and foreign producers. If the rates of duty, as fixed in 1922, were less than the difference between the foreign cost and domestic cost, a recommendation for an increase of duties was to be made; if greater, a recommendation for a decrease. No change, however, was to be made amounting to more than 50% of the actual duties appearing in the act of 1922. Nominally the tariff commission had no powers in this regard; it merely recommended to the president that the changes should be made. The expectation, however, was that the president should *ipso facto* proceed in accord with the recommendations, and that the system should operate automatically. It represented an endeavour to withdraw the detailed fixing of duties from the legislature, and to entrust the task to a supposedly expert body. The same sort of thing was done by Australia in 1921. A tariff board was then established, with authority to make similar investigations and to report to the minister of trade and customs, who was then empowered to make changes as recommended by the board. In practice this meant that the board made the changes. Boards of a similar sort, though with powers of more distinctly an advisory kind, were established in Great Britain itself, in British India, South Africa, and in the Irish Free State. In Great Britain the board of trade, through a committee, was authorized to make inquiries under the act of 1925 for the safeguarding of industries. The changes recommended by the board of trade had then to be submitted to parliament, and did not go into effect unless sanctioned by parliament. In Ireland an act of 1926 established a tariff commission of three members, required to report the pertinent facts to the minister of finance, but making no specific recommendations.

TARIJA, a department and town of south-eastern Bolivia. The department lies on the northern frontier of Argentina, and is bounded W. by Potosí, N. by Chuquisaca, and E. by Paraguay. Pop. (1915 estimated) 31,567. Area, 164,704 sq.m. The eastern and larger part of the department belongs to the great Chaco lowland region. The Chaco districts are inhabited by small nomadic tribes of Indians, and the grassy Llanos de Manzo by the Chiriguanos, many of whom live in permanent villages, breed horses, cattle and sheep, and till the soil. In the mountains are remnants of the Quichuas, once masters of an empire.

The capital, SAN BERNARDO DE TARIJA (pop. 1924 estimate, 10,843), is the only town of importance in the department. It is situated on the Río Grande de Tarija, about 85 m. E. of Tupiza. It is about 6,500 ft. above sea level and its climate is mild and healthful. The town was founded in 1577 by Luis de Fuertes, by orders of the Viceroy of Peru, as a military post to hold the Chiriguanos in check. About the same time the Jesuits established themselves here, and the most important building in the town is their convent.

TARIM, the river which gives its name to the great basin between the Tien Shan and Kunlun mountain systems of central Asia. The area of the basin is over 350,000 sq.m. and the length of the river may be said to be about 1,000 miles. The mountain frame dies away to the north-east in the arid Gobi, so that beneath the slopes of the Kunlun lies the Kansu highway from China. The river is formed by the confluence of the Kashgar and the Yarkand; it then flows for some 230m. north-eastwards between high banks, bordered by poplars and reeds, and joins the Aksu, a swift and powerful stream from the north; 20m. further on the Khotan river flows in from the south, and after another 150m. it begins to come into direct conflict with the sand dunes of the great desert and to form lateral lakes in the hollows between the great dunes, which the Khotan river has had to fight in the lower part of its course. Numerous streams flow in from the Kunlun northward parallel to and east of the Khotan river, but lose themselves in the desert, and the Khotan reaches the Tarim only some 40 days in a year. Further to the east the Tarim breaks up in deltaic fashion and swings north and south. Here it skirts the north-east front of the great dunes and has a number of long lakes on its course, stretching mostly north to south or north-west to south-east. The lakes act as filters and the river emerges from them bright and clear. A little north of lat. 40, at Airylgan, it receives the Koncheh river, which issues from the lake called Bagrach-Köl. This river has poplars on its left bank which hinder the spread

of the desert from the north-east. Below Airylgan the remains of the river, which has diminished practically all the way down from its confluence with the Aksu, enter the dwindling lakes of Kara-Buran, a sort of ante-room to the real terminal basin of the river, the Kara-Koshun (Lop-Nor, *q.v.*) at an altitude of 2,675 ft. above sea-level. In 1900–01 Dr. Sven Hedin discovered several fresh desert lakes forming to the north of Kara-Koshun, and branches of the deltaic arms of the Tarim, or overflows of such branches, straining out in the same direction; facts which he interpreted as showing a tendency of the river to revert to its former more northerly terminal basin of the old (Chinese) Lop-Nor.

The lower part of the course of the river is, on the whole, moving south-westward into lower ground. Its course is so sluggish that sediment is deposited in its bed, which is thus raised above the surrounding country. The river is usually frozen during December, January and February. The thaw in March causes a flood, followed by a greater one, due to the melting of snows on the mountains, and the high water can be traced down the river during the summer.

The basin is often divided into four main regions:—(*a*) The Takla-Makan desert (*q v.*) or central area of bare drift-sand desert. Its borders on the west, north and east are determined by the belts of vegetation accompanying the Tisnaf, Yarkand and Tarim rivers respectively. The area has outliers beyond these riverine borders. (*b*) The oasis belts south of the Tien-shan, east of the Pamir and north of the Karakorum and Kunlun The oases on the south lie between the gravel glacis of the Kunlun and the sands of Takla-Makan. The best known are Karghalik, Khotan, Keriya, Niya, Cherchen and Charkhlik. Those on the north include Uchturfan, Aksu, Bai-Kuche, Kuerhlei, Karashar, Turfan, Pichan and Hami To the west the two chief ones are Kashgar and Yarkand. The cultivable areas are usually greater in the west and the north than in the south. (*c*) The terminal depression of Lop and the Turfan basin. The Lop basin contains the terminal marshes of the Tarim river, the salt-encrusted bed of the former extension of Lop-Nor beyond the marshes, and the dune-covered area east of the final course of the Tarim river between it and the north-western shore of the old lake The Turfan depression is enclosed on the north by a portion of the Tien-shan; on the west by an outlying range of the same, and on the east and south by the barren hills of the Kuruk Tagh. Within these boundaries there are belts of glacis, desert, oasis-cultivation and dune-covered desert, exactly as one finds them in the Tarim basin. (*d*) The Sulo-Ho basin, and the cultivated area along the route north of the Nan-shan, leading into Kansu from the eastern Tarim. The basin is covered with bare gravel, except for a narrow belt of vegetation accompanying the lower course of the river, and the limited area capable of cultivation by means of irrigation around the oasis of Tun-huang. South of Tun-huang accumulations of drift-sand, approach or overlie the foothills of the Nan-shan

Problems of Climatic History.—The present-day climate of the Tarim basin is discussed in the article on Sin-kiang (*q.v.*), but the problems of its possible changes of climate in the past have been the subject of much investigation during recent years. The expeditions into the Tarim basin which have been undertaken by Sir Aurel Stein and Dr. Sven Hedin have resulted in a great mass of evidence bearing on the problem. This evidence has been interpreted by various authorities, who have each put forward a theory to explain the facts reported by the explorers. The problem is connected with the supposed "desiccation" of Central Asia. (*See* ASIA, *Archaeology*.)

Great changes have come about in the Tarim basin during the last two thousand years. Settlements have been abandoned and fresh ones made; some regions, once prosperous, are now deserted and are quite uninhabitable; rivers have forsaken their old beds, and other rivers do not extend as far as they once did, while the lakes in the centre of the basin appear to be shrinking in size.

Historical Geography.—The Tarim basin lies on a highway of the nations; the main routes through it being in an east-west direction, the northern route along the southern foot of the Tien-shan and the southern one along the northern foot of the Kunlun. Both unite at Kashgar, whence the route leads over the Pamirs to the trans-Caspian lowlands.

The region has always been one having an essentially "corridor" nature. There is not, and never has been, sufficient atmospheric moisture or subterranean water supplies to support a large agricultural population. The narrow belts of riverine jungle could never, within historic times, have afforded the possibility of nomadic existence to any but quite insignificant communities, such as the present Dolans on the Yarkand river. This point is very important, for it explains why the great nomadic tribes of the Wu-sun, Sakas, Yueh-chih, Huns, Turks and Mongols were always ready to raid, or to make tributary, the oases of the Tarim, but never crossed the Tien-shan, permanently to occupy the basin. Nature has denied grazing grounds to the Tarim, and has thus protected it against ever becoming the scene of great migratory movements and the upheavals which accompany them. Within the basin itself, the only basis of life was painstaking agriculture, possible only by means of irrigation. This mode of life did not appeal to the neighbouring nomads; the plateaux of the Tien-shan or the Mongolian steppes were more suitable for them. Because of these conditions, we find each great wave of Central Asian migration moving along the northern foot of the Tien-shan, or even further north

Modern Economic Conditions in the Tarim Basin.—The potential wealth of the Tarim basin is as yet untouched by modern developments. Hitherto its commercial importance as a highway has benefited those people who used the highway. Beyond the protection afforded at times by Chinese troops, and the benefits of an effective administration, which the region enjoyed when Chinese authority was sufficiently strong to assert itself, the native oasis dwellers have not prospered overmuch from the advantages which their land offers to neighbouring peoples as an easy trade route between East and West.

The fertile "loess" which composes much of the western part of the basin is eminently suitable for cultivation The total amount of land under cultivation could be increased if a scientific system of irrigation were developed by the Chinese administrators. The chief obstacle to wider cultivation of the oases is found in the people themselves They are mostly Turki, engaged in either agriculture or commerce, and, although they do not resent foreign interference, they show no desire to enlarge their commercial and agricultural enterprises The attitude of the Chinese in the matter of foreign exploitation of the Tarim basin is very discouraging. Foreign capital is needed to develop the resources of the country, and the Chinese are not anxious to admit this, owing to their dread of alien domination.

The products are chiefly grain of all kinds, wool, cotton and silk. Khotan is the centre of the silk industry, and also the centre of valuable jade deposits. Agriculture is the most important and widespread industry. The natives depend on it for their existence, as foodstuffs are not imported from the neighbouring States. The cotton and jute industries could be turned into a flourishing trade if properly exploited, both products being of excellent quality. Soil, labour and material are there to co-operate in the development of these industries.

The political disturbances in the Tarim basin during the last century and the recent upheavals in China itself have been responsible to a large extent for the commercial apathy prevailing in East Turkistan. (*See* also SIN-KIANG, KASHGAR, KHOTAN, YARKAND, LOP-NOR, and for bibliography *see* ASIA.)

TARKANRÍ or **TARKILANRI**, a Pathan tribe inhabiting the valleys of Bajour, on the border of the North West Frontier Province of India.

TARKINGTON, NEWTON BOOTH (1869–), American author, was born in Indianapolis (Ind.), July 29, 1869. After studying at Phillips academy, Exeter (Mass.), he entered Purdue university, Lafayette (Ind.), but later transferred to Princeton, whence he graduated in 1893. He was a member of the Indiana House of Representatives in 1902–03. One of the most versatile of American writers of fiction, Tarkington won early recognition with his novel, *The Gentleman from Indiana* (1899).

Among his outstanding successes were the charming romance *Monsieur Beaucaire* (1900), which was later presented on the films and on the legitimate stage; the humorous portrayals of boyhood and adolescence, *Penrod* (1914) and *Seventeen* (1916); his delineations of the modern industrial city, *The Turmoil* (1915); *The Magnificent Ambersons* (1918), and *The Midlander* (1924), combined as *Growth* (1927); and *The Plutocrat* (1927). Perhaps his most finished novel is *Alice Adams* (1921), which, like *The Magnificent Ambersons*, was awarded a Pulitzer prize. Tarkington is also the author of a number of plays including *Beauty and the Jacobin* (1912), *Mister Antonio* (1916), *The Man from Home* (1906), and *Up from Nowhere* (1919), the latter two with Harry Leon Wilson.

TARLAC, a municipality (with administration centre and 39 *barrios* or districts) and capital of the rich province of Tarlac, Luzon, Philippine islands. It is located on the central plain of Luzon in the region drained by the Agno river. Pop. (1918), 23,888. Tarlac, located on the Manila-Dagupan railway is an important commercial centre. Two crops of rice are grown annually in the vicinity, one by means of irrigation. Sugar, tobacco, corn, beans, sweet-potatoes, coconuts, pineapples and other products are raised in the region. In 1918, it had 12 manufacturing establishments, 7 rice mills, 16 sugar mills and 43 household industry establishments, with outputs valued at 43,700; 1,700,000, 128,000; and 17,700 pesos respectively. Of the 20 schools, 18 were public. Tarlac was founded in 1686. The language is Pampango, but there are many Tagalogs, Ilocanos and Pangasinans in the municipality and other parts of the province.

TARLETON, SIR BANASTRE (1754–1833), English soldier, the son of John Tarleton (1719–1773), a Liverpool merchant, was born in Liverpool on Aug. 21, 1754. Educated at Oxford, he entered the army and in Dec. 1775 he sailed as a volunteer to America with Earl, afterwards Marquess, Cornwallis. His services during the American War of Independence in 1776, gained him the position of a brigade-major of cavalry. In 1780, as commander of the British legion, a mixed force of cavalry and light infantry, he went to South Carolina, supporting Sir Henry Clinton in the operations which culminated in the capture of Charleston. After taking part in many successful engagements, he marched with Cornwallis into Virginia and was instructed to hold Gloucester. This post, however, was surrendered to the Americans with Yorktown in Oct. 1781, and Tarleton returned to England on parole. From 1790 to 1812, with the exception of one year, he sat as M.P. for Liverpool. In 1794 he was promoted to major-general, and in 1812 general; he held a military command in Ireland and another in England. In 1815 he was made a baronet. He died without issue at Leintwardine, Shropshire, on Jan. 25, 1833.

He wrote a *History of the Campaigns of 1780 and 1781 in the Southern Provinces of North America* (1781) which was criticized by Col. Roderick Mackenzie in his *Strictures on Lieutenant-colonel Tarleton's History* (1781), and in the *Cornwallis Correspondence*.

TARLTON, RICHARD (d. 1588), English actor, according to Fuller (*Worthies* iii. 139) was born at Condover, Shropshire. He was probably at one time an inn-keeper. In 1583 he is mentioned as one of the original company of queen's players and he had become an experienced actor; he was their chief comedian and remained with them until his death. He was Elizabeth's favourite clown, and his talent for impromptu doggerel on subjects suggested by his audience has given his name to that form of verse. For the Queen's men he wrote *The Seven Deadly Sins*. Many songs and witticisms of the day were attributed to him, and after his death *Tarlton's Jests*, many of them older than he, made several volumes. He is said to have been the Yorick of Hamlet's soliloquy.

TARN, a department of France, formed in 1790 of the three dioceses of Albi, Castres and Lavaur, belonging to the province of Languedoc. Pop. (1926) 301,717. Area, 2,231 sq. miles. Tarn is bounded north and east by Aveyron, south-east by Hérault, south by Aude, south-west and west by Haute-Garonne, north-west by Tarn-et-Garonne. The department forms the southern buttress of the Plateau Central, with the Montagne Noire (3,970 ft.) near its southern border. The general slope is from east to west, and in the east the Monts de Lacaune reach 4,154 ft. at the Pic de Montalet. The greater part of the department is floored by ancient rocks with some granite, especially in the north, and the general level is from 1,500 to 2,000 feet. The Aveyron runs along the northern boundary, the Tarn across the middle of the department, and the Agout across the south, and they join one another west of the boundary on their way to Garonne. The Aude receives the streams from a part of the Montagne Noire.

The limestone and sandstone foot-hills are clothed with vines and fruit trees, and are broken by deep alluvial valleys of extraordinary fertility. The eastern portion of the department has the climate of Auvergne, the severest in France, but that of the plain is Girondin. The winter average temperature reduced to sea-level is 41° and the summer average temperature is 70°, but the great elevation often reduces these figures by 15° to 20°. The rainfall, 29 or 30 in. at that place, exceeds 40 in. on the Lacaune and Montagne Noire.

The west and centre produces cereals, wheat, oats, maize, and vines; the valleys around Castres provide natural pasture for cattle; market-gardening is carried on in the west. There are mines of coal and iron, and quarries of lime. The industries include the manufacture of textiles, hosiery, brushes, morocco leather, hats, metal foundries, dye-works and glass-works. The department is famous for its sparkling wines. The department is divided into two arrondissements (Albi and Castres) and there are 36 cantons and 323 communes. The department is in the 16th military region, and the académie (educational division) of Toulouse, where is its court of appeal.

The chief towns are Albi, the capital and seat of an archbishop, with suffragan bishops at Rodez, Cahors, Mende and Perpignan, Castres, Gaillac, Lavaur, Mazamet and Cordes (*qq.v.*). Burlats has ruins of an old church and château; Lisle d'Albi, a *bastide* with a 14th century church, and Penne has ruins of a mediaeval château.

TARN, a river of southern France, 234 m. long, a tributary to the Garonne. It rises at 5,249 ft. on the Hercynian gneisses of Mt. Lozère, flows westward and, having received the Tarnon, enters a gorge in the Jurassic limestones, which separates the Causse de Sauveterre from the Causse Méjan. It receives the Jonte (left) and passes between the Causse Noir, the Larzac plateau and the Causse de St. Affrique (left) and the Lévezou range and the Plateau of Ségala (right). At Millau it receives the Dourbie (left) and lower down the Dourdou (left) and from here to the cascade of Sabo, above Albi, the river crosses Permian and Silurian rocks. Having entered the plain, the river, has cut out a deep bed in the Tertiary strata, passes Gaillac, and, after receiving the Agoût (left), it turns north-west, receiving the Tescou (right) at Montauban, and the Aveyron (right). After passing Moissac it joins the Garonne on its right bank.

TARN-ET-GARONNE, a department of south-western France, formed in 1808 of districts formerly belonging to Guienne and Gascony (Quercy, Lomagne, Armagnac, Rouergue, Agenais), with the addition of a small piece of Languedoc. From 1790 to 1808 its territory was divided between the departments of Lot, Haute-Garonne, Tarn, Aveyron, Gers and Lot-et-Garonne. It is bounded north by Lot, east by Aveyron, south by Tarn and Haute-Garonne, and west by Gers and Lot-et-Garonne. Area, 1,440 sq.m. Pop. (1926) 164,191. The department is the region focussing upon Montauban and includes the junction of the Aveyron and the Tarn and their union with the Garonne. These rivers separate hills of Pliocene strata, and in the extreme north-east stands out the edge of the Plateau Central and the limestone Causse de Quercy (1,634 ft.). The climate is mild and agreeable; the mean annual temperature being about 56° F. Rain falls seldom, but heavily, especially in spring, the annual rainfall being 28 or 30 in.

The wide alluvial valleys of the three large rivers are most productive. Cereals, especially wheat, maize and oats, occupy more than two-thirds of the arable land of the department. The vine is grown everywhere and large quantities of grapes are

exported as table fruit. Potatoes are also grown. Plums and apricots are abundant. The breeding of horses, especially for cavalry purposes, is actively carried on; and the rearing of horned cattle, both for draught and for fattening, is also important. Sheep, pigs, poultry, and silk-worms are also sources of profit. There are metal-foundries, various kinds of silk-mills, and manufactories of straw-hats, wool, paper and brooms. The principal exports are fruit, wine, flour, truffles from the Rouergue, and early vegetables. The canal of the Garonne traverses the department for 48 m and the Garonne and the Tarn furnish 82 m. of navigable waterway. The department is served by the Orléans and the Southern railways. The department forms the diocese of Montauban under the archbishop of Toulouse, and belongs to the académie (educational division) of Toulouse, where is its court of appeal, and to the district of the XVII. corps d'armée (Toulouse). It has two arrondissements (Montauban, the capital, and Castelsarrasin), 24 cantons and 195 communes.

TARNOPOL, a province of Poland, bounded on the north by the province of Volhynia, on the west by Lemberg, on the south by Stanislawów provinces, and on the east by Russia. Area 6,268 sq. miles. Pop. (1921) 1,429,000, of whom 45% are Poles, 49·7% Ruthenians and 4 9% Jews. The Ruthenians belong to the same race and religion as those in Stanislawów province (*q.v.*), but the Poles are more numerous in Tarnopol, since they have been colonizing the Podolian plateau since the 14th century. Tarnopol is part of the plateau of Podolia joining up with the Lublin uplands, having the appearance of hills where the land slopes down to the Volhynian plain, especially in the Gologory. The south is bounded by the Dniester, with its lower valley, the tributaries of which drain the bulk of the province except in the north, where the Bug and Styr have their sources. These tributaries all flow from north to south and from the deep ravines which are a distinctive feature of Podolia The plateau is sometimes flat, sometimes hilly and wooded, as on the Miodobory along the eastern border. The Strypa and the Lipa are famous for the stubborn Russian defence during the World War. Tarnopol is a fertile agricultural province, densely populated with small peasant proprietors. It is famous for its horses and cattle, which thrive on the well-watered pastures. The chief towns are Tarnopol (pop 30,900), Zloczów, Bareżany, Busk, Brody, Zbaraż and Trembowla.

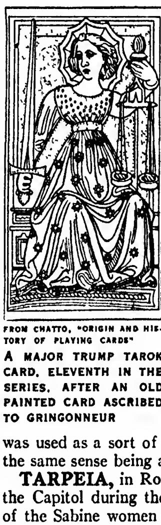
TARNOPOL, a town of Poland, in the province of the same name, 87 m. E S.E. of Lemberg by rail. Pop. (1921) 30,900, half of whom are Jews The town was founded in 1540 by Jan Tarnowski, first of a series of Polish generals It became a fortress and received many privileges from the Polish kings The ancient synagogue of the reign of Casimir the Great remains, and there is a museum. Industry consists in corn milling and the preparation of wax and honey. The chief trade is in horses, agricultural produce and spirits

TARNÓW, town of Poland, in the province of Cracow, 164 m. W.N W. of Lemberg by rail Pop. (1921) 35,700, of whom about 40% are Jews It is situated on the river Biala, not far from its junction with the Dunajec, and is the seat of a Roman Catholic bishop. It possesses a cathedral in Gothic style, built in the 15th century, with monuments of the Tarnowski and Ostrogski families, to which the town formerly belonged, another church, built in 1454, and a diocesan museum with Polish paintings of the 15th and 16th centuries On a hill near the town stand the ruins of an old castle of the Tarnowski family and a small church over 800 years old. The town hall is an old and interesting building Agricultural implements, glass and chicory are manufactured

TARNOWSKI, JAN [called MAGNUS] (1488–1561), Polish general. After a careful education at the palace of Matthew Drzewicki, bishop of Przemysl, he occupied a conspicuous position at court in the reigns of John Albert, Alexander and Sigismund I. In 1509 Tarnowski distinguished himself in Moldavia, taking part in the victories of Wisniowiec (1512) and Orsza (1514). He then travelled in the Near East, and northern and western Europe. While in Portugal he received from King Emanuel the chief command in the war against the Moors, and was promoted by Charles V. to a count of the Empire. On the death of Nicholas Firlej in 1526 Tarnowski became grand hetman of the crown, or Polish commander-in-chief, and won his greatest victory at Obertyn (August 22, 1531) over the Moldavians, Turks and Tatars. Tarnowski took the royal side during the "Poultry War" of 1537; and also in 1548 when the *szlachta* tried to annul by force the marriage of Sigismund Augustus (*q.v.*) with Barbara Radziwill. In 1553, indeed, he was in opposition to the young king; yet he remained emphatically an aristocrat, intensely opposed to the democratic tendencies of the *szlachta,* and working for a firm alliance between the king and the magnates. Though a devout Catholic, he was opposed to the exclusive jurisdiction of the bishops and would have limited the authority of Rome in Poland Tarnowski invented a new system of tactics to increase the mobility and security of the armed camps within which the Poles had so often to encounter the Tatars. His principles are set forth in his *Consilium Rationis Bellicae* (best edition, Posen, 1879). As an administrator he did much to populate the vast south-eastern steppes of Poland

See Stanislaw Orzechowski, *Life and Death of Jan Tarnowski* (Pol.) (Cracow, 1855).

TARO (*Colocasia esculenta*), a coarse herbaceous plant of the arum family (Araceae, *q v*), called also eddo and dasheen, probably native to the Pacific islands, where it is extensively cultivated for its large, spherical, underground tubers, which form an important article of food, especially in Hawaii It is closely allied to or is perhaps a variety of *C. antiquorum,* native to the East Indies, a stately ornamental plant, with large shield-shaped leaves, various cultivated forms of which are known as elephant's-ear



FROM CHATTO, "ORIGIN AND HISTORY OF PLAYING CARDS"

A MAJOR TRUMP TAROK CARD, ELEVENTH IN THE SERIES. AFTER AN OLD PAINTED CARD ASCRIBED TO GRINGONNEUR

TAROK, a game of cards very popular in Austria and Germany, and played to a limited extent in some parts of France. Special cards are used, and the rules are complicated. The name *Tarok* was originally given by the Italians to a certain card in the pack as early as the 13th century, but was afterwards applied to the game itself

TARPAULIN or **TARPAULING** (as if *tarpalling,* from *tar,* and *palling,* a covering, Lat. *palla,* a mantle), and a heavy well-made, double warp plain fabric, of various materials, used chiefly in the manufacture of covers for weather protection To make it proof against rain and other atmospheric influences it is generally treated with tar, though various compositions of different kinds are also employed, especially for the finer fabrics such as are used for motor-car hoods, van tops, etc , which are generally made of flax, hemp and cotton. A lot of tarpaulin is made entirely of jute (*q.v*). Formerly the word was used as a sort of nickname for a sailor, the modern "tar" in the same sense being an abbreviation of it.

TARPEIA, in Roman legend, daughter of the commander of the Capitol during the war with the Sabines caused by the rape of the Sabine women According to the story, she offered to betray the citadel, if the Sabines would give her what they wore on their left arms, meaning their bracelets; instead of this, keeping to the letter of their promise, they threw their shields upon her and crushed her to death. Simylus, a Greek elegiac poet, makes Tarpeia betray the Capitol to a king of the Gauls. The story may be an attempt to account for the Tarpeian rock being chosen as the place of execution of traitors. According to S. Reinach, however, in *Revue archéologique,* xi. (1908), the story had its origin in a rite—the taboo of military spoils, which led to their being heaped up on consecrated ground that they might not be touched. Tarpeia herself is a local divinity, the manner of whose death was suggested by the tumulus or shields devoted to her cult, a crime being invented to account for the supposed punishment.

See Sir George C. Lewis, *Credibility of early Roman History;* A. Schwegler, *Römische Geschichte,* bk. ix. 10; Livy, i. 11; Dion. Halic.

ii. 38–40; Plutarch, *Romulus*, 17; Propertius, iv. 4; Ovid, *Fasti*, i. 261; C. W. Müller, *Frag. Hist. Graec.*, iv. p. 367.

TARPON (*Megalops atlanticus*), a fish allied to the herrings, but with a large mouth and very large, thick, silvery scales. It occurs in the warmer parts of the western Atlantic, and is an active fish, preying on the fry of other fishes. It reaches a length of 7 ft., and a weight of more than 200 lb.

TARQUINIA (anc. TARQUINII), a town of Italy, in the province of Rome, 62 m. north-west by rail from the city of Rome, 490 ft. above sea-level. Pop. (1921), 6,320 (town), 7,972 (commune). It is picturesquely situated, and commands a fine view of the sea. It possesses mediaeval fortifications, and no less than 25 towers are still standing in various parts of the town, which thus has a remarkably mediaeval appearance. The castle, on the north, contains the Romanesque church of S. Maria in Castello, begun in 1121, with a fine portal of 1143, a *ciborium* of 1166 and a pulpit of 1208, both in "cosmatesque" work; the pavement in marble mosaic also is fine. There are several other Romanesque and Gothic churches and other buildings. The Gothic Palazzo Vitelleschi (1439) with remarkably rich windows, contains the fine Government museum, now including the Bruschi collection, of Etruscan antiquities from the tombs of the Etruscan city, which probably occupied the site of the Roman town, now deserted, its last remains having been destroyed by the inhabitants of Corneto (the mediaeval name by which the town was till lately known) in 1307. Scanty remains of walling and of buildings of the Roman period exist above ground.

The importance of Tarquinia to archaeologists lies mainly in its necropolis, situated to the south-east of the mediaeval town, on the hill which, from the tumuli raised above the tombs, bears the name of Monterozzi. The tombs themselves are of various kinds. The oldest are *tombe a pozzo*, or shaft graves, containing the ashes of the dead in an urn, of the Villanova period, the earliest belonging to the stage known as First Benacci (*see* ETRUSCANS) and the latest to the middle or end of the 9th century B.C. immediately after the coming of the Etruscans, a few contemporary graves of whom, containing Egyptianizing scarabs and some gold and silver, have also been found. In some of these tombs hut urns, like those of Latium, are found. Next come the various kinds of inhumation graves, the earliest of which, the so-called warrior's grave, belongs to the early "Vetulonian" period, and the Bocchoris tomb to 730–690 B.C. (MacIver, *Villanovans and Early Etruscans*, 1924, 40–56; 158–166): the most important are rock-hewn chambers, many of which contain well-preserved paintings of various periods.

Tarquinia was the chief of the 12 cities of Etruria, and appears in the early history of Rome as the home of Tarquinius Priscus and Tarquinius Superbus. The people of Tarquinia and Veii attempted to restore Tarquinius Superbus after his expulsion. In 358 B.C. the citizens of Tarquinia captured and put to death 307 Roman soldiers; the resulting war ended in 351 with a 40 years' truce, renewed for a similar period in 308. When Tarquinia came under Roman domination is uncertain, as is also the date at which it became a municipality; in 181 B.C. its port, Graviscae (mod. Porto Clementino), with Government salt-works 4 m. S.W., in an unhealthy position on the low coast, became a Roman colony. It exported wine and carried on coral fisheries.

TARQUINIUS PRISCUS, LUCIUS, fifth legendary king of Rome (616–578 B.C.). He is represented as the son of a Greek refugee, who removed from Tarquinii in Etruria to Rome, by the advice of his wife, the prophetess Tanaquil. Appointed guardian to the sons of Ancus Marcius, he supplanted them on their father's death. He laid out the Circus Maximus, instituted the "great" games, built the great sewers (*cloacae*), and began the construction of the temple of Jupiter on the Capitol. He carried on war successfully against the Sabines and subjugated Latium. He is said to have raised the number of the senators to 300, and to have doubled the number of the knights.

The introduction of many of the insignia of war and of civil office is assigned to his reign, and he was the first to celebrate a Roman triumph, after the Etruscan fashion, in a robe of purple and gold, and borne on a chariot drawn by four horses. He was assassinated at the instigation of the sons of Ancus Marcius.

The legend of Tarquinius Priscus is in the main a reproduction of those of Romulus and Tullus Hostilius. There seems to have been originally only one Tarquinius; later, when a connected story of the legendary period was constructed, two (distinguished as the "Elder" and the "Proud") were introduced, separated by the reign of Servius Tullius, and the name of both was connected with the same events.

For the constitutional reforms attributed to Tarquinius, *see* ROME: *Ancient History;* for a critical examination of the story, Schwegler, *Römische Geschichte*, bk. xv.; Sir George Cornewall Lewis, *Credibility of early Roman History*, ch. 11; W. Ihne, *History of Rome*, i., E. Pais, *Storia di Roma*, i. (1898), who identifies Tarquinius with Tarpeius, the eponymus of the Tarpeian rock. Ancient authorities:—Livy i. 34–41; Dion. Hal. iii. 46–73, Cic. *de Repub.*, ii. 200.

TARQUINIUS SUPERBUS, LUCIUS, son of Lucius Tarquinius Priscus and son-in-law of Servius Tullius, the seventh and last legendary king of Rome (534–510 B.C.). On his accession he proceeded at once to repeal the recent reforms in the constitution, and attempted to set up a pure despotism. Many senators were put to death, and their places remained unfilled; the lower classes were deprived of their arms and the completion of the fortress-temple on the Capitoline confirmed his authority over the city. The outrage of his son Sextus upon Lucretia (*q.v.*) precipitated a revolt, which led to the expulsion of the entire family. All Tarquinius's efforts to force his way back to the throne were vain (*see* PORSENA), and he died in exile at Cumae.

In the story certain Greek elements, probably later additions, may easily be distinguished. Tarquinius appears as a Greek "tyrant" of the ordinary kind; on the other hand, an older tradition represents him as more like Romulus. This twofold aspect of his character perhaps accounts for the making of two Tarquinii out of one (*see* TARQUINIUS PRISCUS). The well-known story of Tarquinius's repeated refusal and final consent to purchase the Sibylline books has its origin in the fact that the building of the temple of Jupiter Capitolinus, in which they were kept, was ascribed to him.

For a critical examination of the story *see* Schwegler, *Römische Geschichte*, bk. xviii.; Sir G. Cornewall Lewis, *Credibility of early Roman History*, ch. 11; E. Pais, *Storia di Roma*, i. (1898); and, for the political character of his reign, ROME: *Ancient History*. Ancient authorities:—Livy i. 21; Dion. Hal. v. 1–vi. 21.

TARRAGON (*Artemisia Dracunculus*), a smooth green herb of the family Compositae, called also estragon, native to Europe and closely allied botanically to the mugwort and wormwood (*qq.v.*). It is widely grown in gardens for its slightly bitter aromatic foliage used in flavouring vinegar, pickles, salads and other dishes.

TARRAGONA, a maritime province in the north-east of Spain, formed in 1833 from the southern part of the province of Catalonia, and bounded on the south-east by the Mediterranean, north-east by Barcelona, north by Lerida, west by Saragossa and Teruel, and south-west by Castellon de la Plana. Pop. (1920) 355,148; area 2,505 sq.m. The Ebro flows through the southern portion of the province, and below Tortosa forms a conspicuous marshy delta, but elsewhere the coast-line is unbroken. The hills are clothed with vineyards, which produce excellent wines, and in the valleys are cultivated all kinds of grain, vegetables, rice, hemp, flax and silk. Olive, orange, filbert and almond trees reach great perfection, and the mountains yield rich pastures and timber. Manufactures are well advanced, and comprise silk, cotton, linen and woollen fabrics, velvet, felt, soap, leather and spirits. There are also many potteries and cooperages and flour, paper and oil mills. Silver, copper, lead and other minerals have been found, and quarries of marble and jasper are worked in the hills.

TARRAGONA, the capital of the Spanish province of Tarragona, a flourishing seaport, and the seat of an archbishop; at the mouth of the river Francoli, 63 m. by rail W.S.W. of Barcelona. Pop. (1920) 27,883.

Tarraco, the capital of the Iberian Cessetani, many of whose coins are extant, was one of the earliest Roman strongholds in Spain. It was captured in 218 B.C. by Gnaeus and Publius Cornelius Scipio, who improved its harbours and enlarged its walls. A Roman monument on a hill 3 m. E. is known as the Sepulcro

de los Escipiones, and locally believed to be the tomb of the Scipios, who were defeated and slain by the Carthaginians under Hasdrubal Barca in 212 B.C., but there is no good reason to believe that the monument is older than the 1st century A.D. As the Colonia Triumphalis, so called to commemorate the victories of Julius Caesar, Tarraco was made the seat of one of the four assize courts (*conventus juridici*) established in Hispania Citerior. Augustus spent the winter of 26 B.C. here, and made Tarraco the capital of the whole province, which received the name of Hispania Tarraconensis. A temple was built in his honour. It was afterwards restored by Hadrian (A.D 117–138), and the city became the Spanish headquarters of the worship of the goddess Roma and the deified emperors. Its flax trade and other industries made it one of the richest seaports of the empire.

To the Romans the Visigoths under Euric succeeded in 467, but on their expulsion by the Moors in 711 the city was plundered and burned. In 1089 the Moors were driven out by Raymond IV of Barcelona, and in 1118 a grant of the fief was made to the Norman Robert Burdet, who converted the town into a frontier fortress against the Moors. In 1705 the city was taken and burned by the British; in 1811, after being partly fortified, it was captured and sacked by the French.

Tarragona is on the coast railway from Barcelona to Valencia, and is connected with the Ebro Valley Railway by a branch line to Reus. The old town, with its dark and steep alleys, occupies a rugged hill which rises abruptly from the sea to an altitude of about 550 ft Many of the houses in this quarter are very old, and are built partly of Roman masonry, one such fragment, immured in the palace wall, is inscribed with the epitaph of a charioteer (*auriga*) Massive ruined walls encircle the old town. Their lowest course is "Cyclopean," consisting of unhewn blocks about 12 ft. long and 6 ft wide; Roman masonry of the Augustan age is superimposed The six gates and the square towers are also, to a great extent, "Cyclopean" Tarragona cathedral is one of the noblest examples of early Spanish art The main body of the building dates from the end of the 12th century and the first half of the 13th, and is of transitional character On the north-east side is a cloister contemporary with the church, with which it communicates by a very fine doorway. The cloister contains much remarkable work, and the tracery of the windows bears interesting marks of Moorish influence Two other noteworthy churches in the city are San Pablo and Santa Tecla la Vieja, both of the 12th century.

There is a fine Roman aqueduct; the Roman amphitheatre was dismantled in 1491 to furnish stone for the eastern mole, though a few rows of seats are left near the sea-shore; and the museum contains a large collection of Roman antiquities. The Torreón de Pilatos is said to have been the palace of the Emperor Augustus. When the monks of the Grande Chartreuse were compelled to leave France, they settled at Tarragona in 1903, and established a liqueur factory. A characteristic feature of Tarragona is the number of its underground storehouses for wine (bodegas); wine is exported in large quantities. There is a British steel file factory; chocolate, soap, flour, ironware, paper, pipes and salted fish are also manufactured.

TARRASA, a town of Spain, in the province of Barcelona, 6 m. W N W of Sabadell on the Barcelona-Lérida railway Pop. (1920) 30,532 Tarrasa was a Roman municipality, and a bishopric from the 5th century to the Moorish invasion in the 8th. Tarrasa is now mostly a modern industrial town.

TARRYTOWN, a village of Westchester county, New York, U.S.A., on the east bank of the Hudson river, 25 m. N. of New York city, opposite Nyack; served by the New York Central railroad, interurban trolleys, motor-bus lines, river steamers and ferry to Nyack. Pop. (1925) 6,199 (State census) North Tarrytown and Irvington, separately incorporated villages of 7,013 and 3,296 inhabitants respectively (1925), adjoin it on the north and south, and are practically part of the same community Tarrytown rises above the river (here expanded into Tappan Zee) to a considerable height The main street (Broadway) is a section of the King's highway laid out in 1723 from New York to Albany, later called the Albany Post road Washington Irving's home "Sunnyside" still stands in the village, and in North Tarrytown are the Philipse manorhouse (built in 1682, partly of brick brought from Holland) and mill (1682) and the old Dutch church (1685). In Sleepy Hollow cemetery, adjoining the church, are some Revolutionary earthworks, and the graves of Washington Irving, Carl Schurz and Robert G. Ingersoll. Among the large modern estates in the environs are those of John D. Rockefeller and Mrs. Finley Shepard (Helen M. Gould) The village has several manufacturing industries and there are large nurseries and market-gardens in the vicinity It is the seat of several private schools. Tarrytown stands on the site of an Indian village, burned by the Dutch in 1644. Settlement by the whites began in 1645, and there were about a dozen Dutch families living here in 1680, when Frederick Philipse acquired title to several thousand acres and built the manorhouse, mill and church mentioned above. During the Revolution Tarrytown was in the "Neutral Territory" between the British and the Continental lines, and was the scene of numerous skirmishes between the "cowboys" and "skinners," unorganized partisans of the Colonies and the king respectively. On the Albany Post road, at a point now marked by a monument, Maj. John André was captured on Sept 24, 1780. Tarrytown was incorporated as a village in 1870, Irvington in 1870 and North Tarrytown in 1875. The name is probably a corruption of the Dutch Tarwen Dorp (wheat town).

TARS, LOW TEMPERATURE, the oily distillates obtained by the destructive distillation of organic substances such as wood, peat, lignite and bituminous coal at temperatures not exceeding 650°C

Wood Tar, obtained as a by-product in the carbonization of wood for the production of charcoal, methyl alcohol and acetone (*qq v.*). Two distinct types of wood tar are recognized. (*a*) hardwood tar and (*b*) resinous wood tar, the former derived from woods such as oak, beech, etc , and the latter from resinous stools and roots and particularly from pinewood

Hardwood Tars. The condensed volatile product of wood distillation is known as crude pyroligneous acid, which has the average composition. water 81%, methyl alcohol 3–4%, acetic acid 6–8%, tar 7%. After settling, the major portion of the tar separates from the aqueous acid although the latter always retains some tar in solution The chemical constituents of wood tar form a very complex mixture comprising the "fatty" acids, esters, ketones, alcohols, phenols (usually polyhydric) and their methyl ethers, together with waxes. The most important representatives of these groups present in the tar are formic and acetic acids, with their methyl esters, acetone, methyl and allyl alcohol, guaiacol, catechol, and esters of pyrogallol

Beech-wood tar is practically the only wood tar subjected to a complete straight distillation. Three fractions are usually collected, first the light oils and water containing acetic acid and methyl alcohol up to 180°C., then the heavy oils up to 240°C and finally the pitch. The important fraction is the "heavy oil" distillate from which beech-wood-tar creosote is obtained (*see* CREOSOTE). The oils from wood-tar distillation receive some application in flotation methods of purification, whilst the pitch is used in briquetting and in insulating compositions.

Resinous Wood Tars are almost wholly represented by pinewood tar, which is commonly termed "Stockholm" or "Archangel" tar and is made extensively in the forests of Russia, Finland and Sweden. It is an important commercial product and differs from hard wood tar in containing the pleasant smelling mixture of terpenes known as turpentine. Pine-wood tar is the residue left after the turpentine has been distilled, usually with the aid of steam. It is used widely in the manufacture of cordage, *e g.*, tarred ropes and twine, and for impregnation of hemp-fibre for oakum. It is used to a slight extent in pharmacy as a component of some ointments and antiseptics. Distillates of pine-wood tar, particularly the creosote fraction, are used in froth flotation processes.

Peat Tar, a jet black, semi-solid oil, lighter than water, which can be dehydrated by heating at 100°C. On distillation up to 360°C. a hard pitch is obtained along with an oily distillate, the latter consisting of a neutral fraction, containing the solid waxes, phenols and only traces of basic compounds. The most striking

characteristic of the neutral oils is their high degree of unsaturation as manifested by absorption of atmospheric oxygen. The waxes, which resemble the *montan wax* of lignite, melt at about 40°C. The acidic (phenolic) constituents of the tar consist of phenol and its homologues, the cresols and xylenols in small quantity, mixed with tar acids boiling at 250–360°C. The latter show a carbolic acid coefficient of 31, *i.e.*, they are 31 times more powerful than phenol as bactericides. Among the phenolic constituents of peat tar, guaiacol, methylguaiacol and a methyl ether of pyrogallol have been identified. These ethers are absent from coal tar, but are found in wood-tar creosote, of which they form the major portion. Peat tar may therefore be looked on as one of the transition steps from wood tar to coal tar. Although the products which can be isolated from peat tar are of undoubted value, the difficulty of winning and drying peat militates against the carbonization of this fuel on an industrial scale.

Lignite and Brown Coal Tars resemble peat tar in many respects. They are usually black oils of a buttery consistency owing to the presence of paraffin wax. Of an average density of 0·95, they retain a high percentage of water but solidify completely at 6–8°C. In contradistinction to tars from bituminous coal, they are almost completely soluble in petrol, a residue of about 5% only being usually left.

They are paraffinoid in nature, the wax content being as high as 10%. The crude wax melts at about 40°C. but from it a series of waxes with melting points from 46° to 73°C. has been obtained. The phenolic constituents resemble those of peat tar and are efficient bactericides. The basic components belong to the pyridine and quinoline series and are chiefly methylated derivatives. A distinctive characteristic of lignite tars is the presence of ketones in the neutral oils—a resemblance to the oils of wood tar. Lignite tars are of increasing importance as a source of fuels for internal-combustion engines, burning and lubricating oils and pitch.

Low-temperature Coal Tars.—(*a*) *Vacuum Tar* has only been produced experimentally with the object of elucidating the composition of coal and the effect of heat upon this material. It is obtained when coal is carbonized at temperatures up to 450° C. under a pressure of 5–40mm. and the average yield is 14 gallons (6·5% by weight) per ton of coal. It is usually lighter than water (sp.gr. 0·99) and is especially interesting in that some of its constituents are identical with substances found in petroleum oils, and extractable from coal itself by solvents such as pyridine. It consists of 40–45% paraffins and naphthenes, 40% "ethylenic" hydrocarbons richer in carbon than mono-olefines, 7% aromatic hydrocarbons, chiefly homologues of naphthalene, and 10% phenols, mostly cresols and xylenols, with smaller amounts of tertiary alcohols and basic compounds. Naphthalene, anthracene, benzene and its homologues are all absent.

Amongst the more interesting constituents of vacuum tar are the naphthene, $C_{30}H_{60}$ called *melene* which is also found in Galician petroleum and in the distillate of bees' wax, and the hydrogenated phenols (alcohols) such as hexahydro-*p*-cresol and its homologues.

(*b*) *Low-Temperature Tar* is produced by the carbonization of bituminous coals, containing 28–35% volatile matter, at temperatures not exceeding 650°C., which is an optimum temperature for the production of gas, tar and smokeless fuel (*see* CARBONIZATION). It is essentially a mixture of those volatile products of coal which are liquid at ordinary temperatures and which have not been subjected to the secondary thermal decomposition incidental to high-temperature carbonization in horizontal retorts. It is therefore regarded as a "primary" tar. Many factors affecting the yield, composition and other characteristics of low-temperature tars have been varied in experimental plants with the result that there have been produced many types of tars to which it has been impossible to assign a common composition. Certain well defined characteristics may be shortly summarized of primary tars obtained by low-temperature carbonization processes which have been commercially established.

Low-temperature tar is usually a brownish black oil, much less viscous than the tar made from the same coal at high temperatures. It is obtained in an average yield of 16–18 gallons per ton of coal carbonized, or 8–9% by weight. This is approximately double the weight obtained by distilling the coal at 900–1,200°C. Its sp. gr. is 1·02–1·07, and owing to the low temperature at which it is formed, it is mainly paraffinoid in character, whereas high-temperature tar is almost wholly aromatic.

The most distinctive characteristics of low temperature tar are the almost entire absence of benzene and its homologues, naphthalene, anthracene and phenol; the unsaturated nature of the neutral oils, from which can be isolated solid paraffins; and the presence of solid, amorphous compounds, of either basic or phenolic nature.

The crude tar is a most unstable product and begins to decompose at about 200° C., finally yielding, when distilled to 360°C., an average of 65% oily distillate and 35% pitch. The amount of pitch formed on distilling low-temperature tar is therefore only half that obtained in a similar operation with high-temperature tar. The former, too, contains much less "free carbon" (*i.e.*, matter insoluble in benzene) than the latter, the average amount being 2–4%. By modified extractions with caustic soda and sulphuric acid (*see* COAL TAR) the crude distillate can be divided into (i.) neutral oils, (ii.) phenols and (iii.) bases.

(i.) *Neutral oils* consist almost wholly of paraffins, naphthenes and olefines, with comparatively small amounts of methylated derivatives of naphthalene and anthracene. On treatment with concentrated sulphuric acid, the neutral oils are absorbed with the exception of some 12% consisting mainly of paraffins. Crude solid wax representing over 1% of the tar is obtained on cooling an acetone solution of the neutral oils. In the paraffin series, all the lower members have been identified, and in the higher ranges, the solid members from $C_{28}H_{58}$ to $C_{29}H_{60}$. The latter melt at 62°C. α- and β-*methylnaphthalenes* have been isolated, but no naphthalene. Similarly β-*methylanthracene* occurs in a complex mixture of hydrocarbons crystallizing on cooling the high fractions of the distillates, but anthracene is absent. No phenanthrene or carbazole has been found, and in place of the hydrocarbons fluorene, acenaphthene and diphenyl, there occur the fully hydrogenated products, *perhydrofluorene, perhydroacenaphthene* and *dodecahydrodiphenyl.*

(ii.) *Phenols.* The extraction of the phenolic constituents of the tar or its distillates is complicated by the fact that resinous and asphaltic substances accompany the phenols in solution in the alkali. These impurities, however, can be eliminated by agitation of the alkaline solution with organic solvents or by saturation with salt. The crude phenols (10–20% of the tar) obtained on acidification as a black oil, can be further purified by extraction with light petroleum, followed by precipitation of the residue from an ethereal solution by fresh petroleum. The petroleum extract consists of low-boiling phenols including *phenol* itself, the *cresols* and 1:2:4-, 1:3:5-, 1:3:4-, and 1:4:2- xylenols. *Catechol,* β-*naphthol* and *trimethylphenols* have also been identified. The higher phenols of the tar are amorphous solids varying in colour from pale yellow to black.

(iii.) *Bases.* The crude bases, representing 2–3% of the tar, are also composed of a low mobile fraction and a higher viscous fraction containing solid, amorphous substances of unknown constitution. The lower bases consist of pyridine and quinoline with their mono-, di- and tri- methyl derivatives. Only traces of primary bases are present in the tar. There have been identified *pyridine, 2-methylpyridine,* 2:4-*dimethylpyridine,* 2:4:6-*trimethylpyridine, aniline, quinoline* and 2-*methylquinoline.* Stable sulphur compounds are present in all fractions of the tar and are only destroyed by treatment with granular sodium at high temperatures.

Utilization of Low-Temperature Tar Products.—The commercial possibilities of low-temperature tar have not yet been fully developed, but its application in various directions has been demonstrated. The low-boiling distillates, owing to their "unsaturated" nature, form satisfactory fuel possessing certain anti-detonating qualities. It has been claimed that the higher fractions of the neutral oils form an exceptionally good lubricant, whilst the "middle" or "dead" oils are suitable for combustion in the Diesel engine. Special characteristics are also claimed for low-temperature tar pitch, which can be used along with or in place of high-temperature tar pitch.

BIBLIOGRAPHY.—C. H. Lander and R. F. McKay, *Low Temperature Carbonisation*, 1924; W. A. Bone, *Coal and its Scientific Uses*, 1922. (D. D. P.)

TARSIER, a small lemur-like animal, *Tarsius spectrum*, of the Malay Peninsula and islands, and typifying a sub-order. The name tarsier refers to the great elongation of two of the bones of the tarsus, or ankle, and *spectrum* to the huge goggle-like eyes and attenuated form which constitute two of the distinctive features of this creature. In organization the tarsier in several particulars approximates to monkeys. Rather smaller than a squirrel, with dusky brown fur, it has immense eyes, large ears, a long thin tail, tufted at the end, and disc-like adhesive surfaces on the fingers, which assist the animal in maintaining its position on the boughs. Four species of the genus are recognized, whose range includes the Malay Peninsula, Java, Sumatra, Borneo, Celebes and some of the Philippines. The tarsier feeds on insects and lizards, sleeps during the day, but is active at night, moving by jumping, an action for which the structure of its hind-legs is well adapted. It is rare, not more than two being found together, and only brings forth one young at a time. It appears to be nearer the ancestral tree of man than any other of the lemurs. (*See* PRIMATES.)

TARSUS (mod *Tersous*), an ancient city in the fertile plain of Cilicia. The small river Cydnus flowed through the centre of the town, and its cool swift waters were the boast of the city. The city is first mentioned on the Black Obelisk, as captured by the Assyrians *c.* 850 B.C. It was probably an old Ionian colony, settled (like Mallus) under the direction of Clarian Apollo. Its importance was due (1) to its excellent and safe harbour, (2) to its possession of a fertile territory, and (3) to its command of the first waggon-road made across Mount Taurus, which was cut through the Cilician Gates, a narrow gorge 100 yards in length, originally only wide enough to carry the waters of a small affluent of the Cydnus. The greatness of Tarsus rested therefore mainly on the two great engineering works, the harbour and the road

Tarsus is most accessible from the sea or from the east. Even after the "Cilician Gates" were cut, the crossing of Taurus was a difficult operation for an invading army (as Xenophon and Arrian show) Hence Tarsian history (where not determined by Greek maritime relations) has been strongly affected by Semitic influence, and Dion Chrysostom, about A D 112, says it was more like a Phoenician than a Hellenic city (which it claimed to be). After the Assyrian power decayed, princes, several of whom bore the name or title Syennesis, ruled Tarsus before and under Persian power. Persian satraps governed it in the 4th century B C.; and struck coins with Aramaic legends there. The Seleucid kings of Syria for a time kept it in a state of servitude; but it was made an autonomous city with additional citizens (probably Argive Greeks and Jews) by Antiochus IV Epiphanes in 171 B C; and then it began to strike its own coins. It became one of the richest and greatest cities of the East under the Romans after 104 B C., and was favoured by both Antony and Augustus: the reception there by the former of Cleopatra, who sailed up to the city in a magnificent vessel, was a striking historic event. In spite of its oriental character, it maintained a university where Greek philosophy was taught by a series of famous Tarsians, who influenced Roman history. Chief among them was Athenodorus Cananites (*q.v.*), teacher and friend of Augustus for many years, a man of courage and power, who remodelled the Tarsian constitution (making it timocratic and oligarchic).

Tarsus depended for its greatness on commerce, peace and orderly government. It was not a strong fortress, and could not be defended during the decay of the empire against barbarian invasion. The Arabs captured the whole of Cilicia shortly after A D. 660; and Tarsus seems to have been a ruin for more than a century after the conquest But Harun al-Rashid rebuilt its walls in 787, and made it the north-western capital of the Arab power in the long wars against the Byzantine empire. All the raids, which were made in Asia Minor regularly, year by year, sometimes twice in one year, through the Cilician Gates and past the fortress Loulon, issued through the north gate of Tarsus, which was called the "Gate of the Holy War." The western gate is still standing, and is misnamed "St. Paul's Gate." The caliph Mamun died on such a foray in A.D. 833, having caught a chill at a great spring north of the Cilician Gates beside Ak-Keupreu. He was brought to Tarsus where (like the emperor Tacitus) he died, and (like the emperor Julian) was buried. His illness recalls the fever which Alexander the Great contracted from bathing in the Cydnus. Nicephorus Phocas reconquered Tarsus and all Cilicia for the empire in A.D. 965. In the First Crusade Baldwin and Tancred captured Tarsus A D 1099, and there the two leaders had a serious quarrel. It formed part of the kingdom of Lesser Armenia for great part of the three centuries after A D. 1180, and it was fortified by Leo II. and Hethoum I. But Turkoman and Egyptian invaders disputed its possession with the Greek emperors and Armenian kings and with one another. Finally it passed into Ottoman hands about the beginning of the 16th century.

The ruins of the ancient city are very extensive, but they are deeply buried, and make little or no appearance above the surface except in the Dunuk Tash (popularly identified as the "Tomb of Sardanapalus," a monument which, however, was at Anchiale, not at Tarsus). This shapeless mass of concrete was probably the substructure of a Graeco-Roman temple, from which the marble coating has been removed The modern town has considerable bazaars and trade; but the climate is very oppressive, owing to the proximity of vast marshes which occupy the site of the harbour and the lower part of the original Cydnus course. The river was diverted from its former course by Justinian in the 6th century. The emperor's intention was only to carry off the surplus waters in time of flood and prevent inundations in the city, not to deprive Tarsus of what was its chief pride and boast; but gradually the neglect of subsequent centuries allowed the channel in the city to become blocked by accumulation of soil, and now the whole body of water flows in the new channel east of the city, except what is drawn off by an artificial irrigation course to water the gardens on the western side of the city. The population in 1927 was 73,680.

BIBLIOGRAPHY—The literature regarding Tarsus is scanty, and few ancient inscriptions have been published *See* W B Barker, *Lares and Penates* (1853), G F. Hill in the British Museum Catalogue of Coins, Six in *Numismatic Chronicle* (1884), pp. 152 ff, 1894, pp 329 ff; E. Babelon in the Catalogue Bibl. TARTAGLIA or TARTALEA, **NICCOLO** [Nicola Fontana] (*c.* 1506–1559), Italian mathematician, was born at Brescia. His childhood was passed in dire poverty. During the sack of Brescia in 1512, he was horribly mutilated by some French soldiers From these injuries he slowly recovered, but he long continued to stammer in his speech, whence the nickname "Tartaglia." He was self-taught, but we find him at Verona in 1521 an esteemed teacher of mathematics. In 1534 he went to Venice. For Tartaglia's solution of cubic equations, which he derived from his master Scipione Ferro (d. 1525), and his contests with Antonio Marie Floridas, *see* ALGEBRA: *History*. In 1548 Tartaglia accepted a situation as professor of Euclid at Brescia, but returned to Venice at the end of 18 months. He died at Venice in 1559.

Tartaglia's first printed work, entitled *Nuova scienzia* (Venice, 1537), dealt with the theory and practice of gunnery. He found the elevation giving the greatest range to be 45o, but failed to demonstrate the correctness of his intuition. His *Quesiti et invenzioni diverse* (1546), a collection of the author's replies to questions addressed to him, was dedicated to Henry VIII. of England. Problems in artillery occupy two out of nine books;

the sixth treats of fortification; the ninth gives several examples of the solution of cubic equations. He published in 1551 *Regola generale per sollevare ogni affondata nave, intitolata la Travagliata Invenzione* (an allusion to his personal troubles at Brescia), setting forth a method for raising sunken ships, and describing the diving-bell, then little known in western Europe. His largest work, *Trattato generale di numeri e misure*, is a comprehensive mathematical treatise (Venice, 1556, 1560). He published the first Italian translation of Euclid (1543), and the earliest version of some of the works of Archimedes (1543), including *De insidentibus aquae*, of which his Latin now holds the place of the lost Greek text. Tartaglia claimed the invention of the gunner's quadrant.

Tartaglia's own account of his early life is contained in his *Quesiti*, lib. vi., p. 74. *See* also Buoncompagni, *Intorno ad un testamento inedito di N. Tartaglia* (Milan, 1881); Rossi, *Elogi di Bresciana illustri*, p. 386. Tartaglia's writings on gunnery were translated into English by Lucar in 1588, and into French by Rieffel in 1845.

TARTAN, a worsted cloth woven with alternate stripes or bands of coloured warp and weft, so as to form a chequered pattern in which the colours alternate in "sets" of definite width and sequence. The weaving of particoloured and striped cloth cannot be claimed as peculiar to any special race or country, for such checks are the simplest ornamental form into which dyed yarns can be combined in the loom. But the term tartan is specially applied to the variegated cloth used for the principal portions of the distinctive costume of the Highlanders of Scotland. For this costume, and the tartan of which it is composed, great antiquity is claimed, and it is asserted that the numerous clans into which the Highland population were divided had each from time to time a special tartan by which it was distinguished. After the rebellion of 1745 various acts of parliament were passed for disarming the Scottish Highlanders and for prohibiting the use of the Highland dress in Scotland, under severe penalties. These acts remained nominally in force till 1782, when they were formally repealed, and since that time clan tartan has, with varying fluctuations of fashion, been a popular article of dress, by no means confined in its use to Scotland alone; and many new and imaginary "sets" have been invented by manufacturers, with the result of introducing confusion in the heraldry of tartans, and of throwing doubt on the reality of the distinctive "sets" which at one time undoubtedly were more or less recognized as the badge of various clans.

Undoubtedly the term tartan was known, and the material was woven, "of one or two colours for the poor and more varied for the rich," as early as the middle of the 15th century. In the accounts of John, bishop of Glasgow, treasurer to King James III., in 1471, there occurs, with other mention of the material, the following:—"Ane elne and ane halve of blue Tartane to lyne his gowne of cloth of Gold." It is here obvious that the term is not restricted to particoloured chequered textures. In 1538 accounts were incurred for a Highland dress for King James V. on the occasion of a hunting excursion in the Highlands, in which there are charges for "variant cullorit velvet," for "ane schort Heland coit," and for "Heland tartane to be hose to the kinge's grace." Bishop John Lesley, in his *De origine, moribus, et rebus gestis Scotorum*, published in 1578, says of the ancient and still-used dress of the Highlanders and Islanders, "all, both noble and common people, wore mantles of one sort (except that the nobles preferred those of several colours)." A hint of clan tartan distinctions is given by Martin Martin in his *Western Isles of Scotland* (1703), which work also contains a minute description of the dress of the Highlanders and the manufacture of tartan.

The following lines give a brief description of the colours of the tartans of the principal clans. The kilt-tartan colour is given in each case; the plaid-tartans vary in slight particulars.

Campbell of Breadalbane, light green, crossed with darker green, the stripes broad with narrow edging of yellow. *Campbell of Argyll*, light green crossed with dark green, narrow independent cross lines of white. *Cameron*, brick-red with broad chequered cross of same colour, edged white and with broad centre of ground colour, two independent cross lines of green. *Forbes*, yellow green, crossed with broad dark-green lines, centred black, independent cross lines yellow. *Fraser*, red ground, main cross lines red with deeper red centre edged with blue, independent cross lines blue. *Gordon*, dark blue-green ground, with broad cross lines of lighter green, narrow centre line yellow. *Graeme*, light green ground, crossed with darker green in small chequer, independent cross lines dark green. *Grant*, scarlet, with broad black-edged scarlet crossings, black independent cross lines. *Macdonald of Glengarry and Keppoch*, red, with open broad blue cross lines, and two independent blue crossings. *Macdonald of Glencoe*, green with broad dark-green crossing, the whole covered with fine red lines. *Macdonald of Clanranald*, light green with broad dark-green crossing, covered with fine red lines. *Macgregor*, scarlet, with narrow scarlet cross lines, edged and centred blue, widely spaced. *Mackintosh*, red with blue-edged and centred crossings of red, and independent blue cross lines. *Mackenzie*, blue-green, broad crossing of same colour with darker edges, independent cross lines, alternately red and white, over the main crossings. *Macleod*, green, with dark-green crossings, over crossings, every other square, a red line. *Macpherson*, pale grey, four darker grey bars at crossings, the whole covered with red double independent lines. *Munro*, red with broad green stripe and narrow lines forming a check of black and yellow. *Murray*, green, close crossings of darker green, independent lines red. *Stewart*, scarlet, deep coloured crossings with scarlet centre, fine widely spaced dark independent lines.

See W. and A. Smith, *Tartans of the Clans of Scotland* (1850); J. Sobieski Stuart, *Vestiarium Scoticum* (1842); R. R. M'Ian, *Clans of the Scottish Highlands* (1845–46); J. Grant, *Tartans of the Clans of Scotland* (Edinburgh, 1885).

TARTAR, in chemical technology, a name applied to crude acid potassium tartrate (bitartrate of potash) deposited in wine casks or vats during the process of vinous fermentation as a crystalline crust of "argol," containing about 75% of potassium bitartrate. This argol when partly purified by recrystallisation is known as "tartar," and when further purified and freed from colouring matter it becomes "cream of tartar." Cream of tartar is used medicinally as a diuretic and purgative.

The term "tartar" was formerly employed in a wider generic sense by the iatrochemists who included under this heading both the above *tartarus vini* and various substances obtained from it and even salts such as salt of sorrel (potassium oxalate) which resembled it. Thus *sal fixum tartari* was dry potassium carbonate which on exposure to air deliquesced to *oleum tartari per deliquium*. Neutral potassium tartrate was termed *tartarus tartarisatus* because it was prepared by neutralising ordinary tartar with the *sal fixum* (K_2CO_3). *Spiritus tartari* employed by Paracelsus was prepared by dry distillation of tartar. This iatrochemist also used the term in a still wider sense to signify abnormal sediments deposited from animal secretions such as the concretionary masses separating in the liver, kidney or bladder, and usually referred to as "stone."

Wine "Lees" and Argol.—Tartaric acid occurs in the juices of various fruits particularly the grape and tamarind. With the grape this acid passes into the expressed juice and during fermentation a deposit of sparingly soluble acid potassium tartrate is thrown down which forms the "lees" of wine. During the process of maturing, a further quantity of this tartrate is precipitated and the deposit of "argol" constitutes the main source of commercial tartaric acid.

Cream of Tartar.—Granulated argol is dissolved to saturation in boiling water and the clear solution allowed to crystallise. The coloured crystals are redissolved in hot water and decolorised by means of pipeclay or egg albumen. On subsequent crystallisation, small, hard, colourless, transparent, rhombic prisms are obtained of cream of tartar. This salt dissolves in 15 parts of hot water but requires for solution 416 parts of water at 0° C. It dissolves freely in solutions of boric acid or borax giving soluble cream of tartar, a white powder, permanent in air when made with boric acid but deliquescent when prepared with borax. Rochelle salt or potassium sodium tartrate, KNa ($C_4H_4O_6$), a purgative drug, is made by dissolving cream of tartar in aqueous sodium carbonate. On ignition cream of tartar evolves inflammable gases and leaves a residue of potassium carbonate and carbon.

Tartar Emetic (potassium antimonyl tartrate),

$K.(SbO)C_4H_4O_6, \frac{1}{2}H_2O$,

a long-known drug, being mentioned by Basil Valentine, is prepared by warming 3 parts of antimony oxide or powder of algaroth (*q.v.*) with four parts of cream of tartar in presence of water It separates from the filtered solution in colourless octahedra which gradually lose their combined water, becoming opaque. It is soluble in 14·5 parts of cold and 1·9 parts of hot water. It has a nauseous metallic taste and produces vomiting when taken internally. In large doses it is poisonous. Besides its medicinal use it is employed as a mordant in dyeing and calico printing (G. T. M.)

TARTARIC ACID, is now one of the most important of the organic acids and probably one of the first to be recognised, for its sparingly soluble acid potassium salt (*see* TARTAR) was known to the Greeks and Romans in the form of a deposit from fermented grape juice K. W Scheele first isolated tartaric acid in 1769 by boiling tartar with chalk and decomposing the product with sulphuric acid. Ordinary tartaric acid crystallises from water in large colourless hemihedral monoclinic prisms containing no water of crystallisation It melts at 168–170° C and at higher temperatures decomposes into a variety of products; its formula is $C_4H_6O_6$ (*See* PYRUVIC ACID.)

Manufacture.—The starting material, argol or wine lees, is boiled with dilute hydrochloric acid and the solution treated with milk of lime and calcium carbonate, when calcium tartrate is precipitated This deposit is then decomposed with dilute sulphuric acid, when sparingly-soluble calcium sulphate remains largely undissolved whereas the tartaric acid passes into solution, which is concentrated to the crystallising point in vacuum pans. The liquid is then cooled in tubs by stirring in order to obtain the crude tartaric acid in granular form. This product is redissolved in water and the solution decolorised by heating with animal charcoal previously freed by acid from calcium phosphate. The clear solution is concentrated and allowed to crystallise, when purified commercial tartaric acid is obtained.

Applications.—Tartaric acid is used as a mordant in wool dyeing It is employed by the calico printer in conjunction with bleaching powder for the liberation of chlorine, as a resist for alumina and other basic mordants and in the discharge colours for Turkey red. By successive nitration and autoxidation, tartaric acid is converted into dinitrotartaric acid and dihydroxytartaric acid, the latter being an intermediate in the manufacture of the wool dye, tartrazine. Tartaric acid also serves in certain photographic processes for printing and developing. It is employed for the production of baking powders, Seidlitz powders, sherbet and similar effervescent drinks. Medicinally it is used to make saline draughts and cooling drinks for febrile and diabetic patients. If unneutralised it must be taken in largely diluted solution otherwise severe gastroenteritis may result. Lime water, magnesia and alkalis are antidotes

Chemical Properties.—Tartaric acid is oxidised by hydrogen peroxide in presence of ferrous salts to dihydroxymaleic acid (H. J. H. Fenton, 1894) and reduced by hydriodic acid and phosphorus to malic and succinic acids. Tartaric acid prevents the precipitation by alkalis of many metallic hydroxides (*e g*, copper and iron) Calcium chloride gives a white calcium tartrate in neutral solution, the precipitate being soluble in cold aqueous potash but reprecipitated on boiling. Added to concentrated sulphuric acid containing 1% of resorcinol, tartaric acid develops a violet red coloration With warm ammoniacal silver nitrate it furnishes a silver mirror.

Stereoisomeric Tartaric Acids.—Four varieties of tartaric acid are recognised. (1) The ordinary dextrorotatory tartaric acid found either free or as potassium and calcium tartrates in the juices of tamarinds, mulberries, pineapples, unripe beetroot and especially in grapes; (2) laevorotatory tartaric acid which does not occur in nature but is obtained by the resolution of the salts of racemic acid. Its chemical properties are identical with those of the dextro-acid and in all its physical properties it resembles this acid except that it turns the plane of polarisation of light to the left and its crystalline salts show hemihedral faces like those of the dextro-acid but oppositely situated, as object to mirror image; (3) racemic acid, $(C_4H_6O_6)_2,2H_2O$, which is obtained from the tartar mother-liquor, melts at 206° C and is produced synthetically by the oxidation of fumaric acid or by mixing molecular proportions of the *d*- and *l*-acids; (4) mesotartaric acid, melting at 143° C, is obtained when cinchonine tartrate is heated for some time at 170° C, and also by the oxidation of maleic acid; it is inactive like racemic acid, but unlike the latter is not resolvable into optically active varieties. The chemical study of the optical properties of these four tartaric acids by L. Pasteur forms the foundation of our modern conceptions of stereoisomerism. (*See* STEREOCHEMISTRY.) (G. T. M.)

TARTARUS, in Greek mythology, the son of Aether and Gē, father of Typhoeus and the giants. In the *Iliad* the word denotes an underground prison, as far below Hades as earth is below heaven, in which those who rebelled against the will of Zeus were confined. In later commentaries Tartarus is the place of punishment of the wicked after death, and is used for the underworld generally. (*See* ABYSS)

TARTINI, GIUSEPPE (1692–1770), Italian violinist, composer and musical theorist, was born at Tirano, Istria, on April 8, 1692. In early life he studied, with equal want of success, for the church, the law courts and the profession of arms. As a young man he was wild and irregular, and he crowned his improprieties by clandestinely marrying the niece (or the daughter of a dependent) of Cardinal Cornaro, archbishop of Padua The cardinal resented the marriage and Tartini, thinking his life in danger, fled for safety to a monastery at Assisi, where his character underwent a complete change. He studied the theory of music under Padre Boemo, the organist of the monastery, and learned to play the violin in so masterly a style that his performances in the church became the wonder of the neighbourhood For more than two years his identity remained undiscovered, but one day the wind blew aside a curtain behind which he was playing. His retreat was betrayed to the cardinal, who, hearing of his changed character, readmitted him to favour and restored him to his wife

Tartini next removed to Venice, where he repaired, by the aid of good instruction, the shortcomings of his own self-taught method After a period of study at Ancona, he returned to Padua, where he was appointed solo violinist at the church of San Antonio From 1723 to 1725 he acted as conductor of Count Kinsky's private band in Prague In 1728 he founded a school for the violin in Padua The date of his presence in Rome does not seem to be clearly established, but he was in Bologna in 1739 Afterwards he returned to his old post in Padua, where he died on Feb. 16, 1770.

Tartini's numerous compositions illustrate his passionate and masterly style of execution, in which he surpassed all his contemporaries. He frequently headed his pieces with an explanatory poetical motto, such as "Ombra cara," or "Volgete il riso in pianto o mie pupille" He told Lalande in 1766 that the sonata known as *Il Trillo del Diavolo*, or *The Devil's Sonata,* was the fruit of a dream, in which the devil played an exquisite sonata. Tartini's first book of sonatas was published at Amsterdam in 1734, the second at Rome in 1745, and many chamber works appeared during his lifetime

Tartini contributed to the science of acoustics by his discovery (independently of Sorge, 1740, to whom the primary credit is now given) of what are still called "Tartini's tones" (*see* SOUND AND HEARING), or differential tones. When any two notes are produced steadily and with great intensity, a third note is heard, whose vibration number is the difference of those of the two primary notes. It follows from this that any two consecutive members of a harmonic series have the fundamental of that series for their difference tone—thus, $\frac{E}{C}$, the fourth and fifth harmonic, produce C, the prime or generator, at the interval of two octaves under the lower of those two notes; $\frac{E}{G}$, the third and fifth harmonic, produce C, the second harmonic, at the interval of a 5th under the lower of those two notes. The discoverer was wont to tell his pupils that their double-stopping was not in tune

unless they could hear the third note; and Henry Blagrove (1811–1872) gave the same admonition. Tartini made his observations the basis of a theoretical system which he set forth in his *Trattato di Musica, secondo la vera scienzia dell' Armonia* (Padua, 1754) and *Dei Principij dell' Armonia Musicale* (Padua, 1767; Eng. trans. 1771). He also wrote a *Trattato delle Appogiature,* posthumously printed in French, and an unpublished work, *Delle Ragioni e delle Proporzioni,* the MS. of which has been lost.

TARTU [Dorpat], a town of Estonia, situated on the Embach, in 58° 23′ N. and 26° 23′ E. Pop. (1924) 50,000. Until the formation of the Estonian State in 1918 the town was called Dorpat. The name Tartu means lowland of Tar or Taara, a god of Estonian mythology probably related to the Scandinavian Thor. The principal part of the town lies south of the river, and the more important buildings are clustered round the two eminences known as the Domberg (cathedral hill) and the Schlossberg (castle hill), which in the middle ages were occupied by the citadel, the cathedral and the episcopal palace. Owing to a great fire in 1777, the town is almost entirely modern; and its fortifications have been transformed into tree-lined promenades. Besides a good picture gallery in the *Ratshof,* and the 13th-century church of St. John, Tartu possesses a university, with an observatory, an art museum, a botanical garden and a library of 250,000 volumes, which are housed in a restored portion of the cathedral, burned down in 1624. A National Museum of Estonia was founded in 1892 and contains a fine ethnographic section.

The university was founded by Gustavus Adolphus of Sweden in 1632; but in 1699 teachers and students removed to Pernau on the advance of the Russians, and on the occupation of the country by Peter the Great again took flight to Sweden. In spite of the treaty of 1710 and the efforts of the Livonian nobles, it was not till 1802 that its restoration was effected under the patronage of Alexander I. Down to 1895, in which year it was thoroughly Russified, the university was German in spirit and in sentiment. It is now attended by some 4,500 students. The astronomical department is famous, owing partly to the labours of F. G. W. von Struve (1820–39), and partly to Fraunhofer's great refracting telescope, presented by the emperor Alexander I.

The foundation of Dorpat is ascribed to Yaroslav, prince of Kiev, and is dated 1030. In 1224 the town was seized by the Teutonic Knights, and in the following year Bishop Hermann erected a cathedral on the Domberg. From that date till about 1558 the town enjoyed great prosperity, and the population reached 50,000. In 1558 it was captured by the Russians, but in 1582 was yielded to Stephen Bathori, king of Poland. In 1600 it fell into the hands of the Swedes, in 1603 reverted to the Poles, and in 1625 was seized by Gustavus Adolphus of Sweden. The Russians again obtained temporary possession in 1666, but did not effect a permanent occupation till 1704. In 1708 the bulk of the population were removed to the interior of Russia. The town passed from Russian to Estonian rule in 1918, but suffered much both during the German occupation and during the later struggle with the Bolshevists.

TARWEED, the name given in the United States to various plants of the tribe Madieae of the family Compositae (*q.v.*), natives chiefly of the Pacific coast of North America. They are mostly annuals, with showy yellow or white flowers. Some 25 species occur in California, Oregon and Washington. Several of these, as the yellow tarweed (*Hemizonia virgata*), the coast tarweed (*H. corymbosa*) and the clustered tarweed (*H. fasciculata*), are valuable honey plants. The most widely known species is the Chile tarweed (*Madia sativa*), native to Chile and naturalized in California and Oregon, a useful forage plant, the seeds of which yield a pleasant, edible oil.

TASCHEREAU, SIR HENRI ELZEAR (1836–1911), chief justice of Canada, was born at St. Mary's in Beauce county (Quebec), on Oct. 7, 1836, the son of P. E. Taschereau. He was educated at the Seminary of Quebec, and was called to the bar there in 1857, becoming a Q.C. in 1867. He entered parliament, and was elected conservative member for Beauce county in the Legislative assembly (1861–67). He gained a reputation in 1874–75 with his work on *Criminal Law Consolidation and Amendment Acts of 1869 for the Dominion of Canada with Notes, Commentaries, etc.* (vol. i. Montreal, 1874; vol. ii. Toronto, 1875, and later editions); and soon afterwards published *Le Code de Procédure Civile du Bas-Canada* (Quebec, 1876). He became successively puisne judge of the superior court of Quebec (1871), judge of the supreme court of Canada (1878), and chief justice of Canada (1902–06), being knighted in 1902. In 1895 he had become dean of the faculty of law at Ottawa university, where he had previously held a chair. Taschereau became a member of the judicial committee of the privy council in 1904. He died at Ottawa on April 14, 1911.

TAS-DE-CHARGE, in architecture, a French term for which there is no English equivalent, given to the lower courses of a Gothic vault, which are laid in horizontal courses and bonded into the wall; they generally rise about one-third of the height of the vault, and as each course projects beyond the course below, following the curve of the vault, they lessen the span to be vaulted.

TASHI-LHÜNPO: *see* Shigatse.

TASHKENT or **TASHKEND,** a city of Asiatic Russia in the Uzbek S.S.R., in 41° 30′ N., 69° 20′ E., situated in a loess oasis, watered by the interlocking Chirchik and Keles tributaries of the Syr-Darya. Irrigation cultivation is very ancient in the oasis; the town itself dates back at least to the seventh century A.D. In 582 the Turks of Transoxiana divided into two khanates, the western one having two headquarters, one at Urumchi and one north of Tashkent, and it is recorded that the Chinese in 659 claimed the territory of the western Turks, including Tashkent. It was captured in 1865 by the Russians and was made the administrative centre of the former Government of Russian Turkestan. The Russians then built a new town nearly 8 m. long and 4 m. broad, considerably to the north-east of Eski-tashkent (old Tashkent), which is now practically deserted.

The houses are low because of frequent earthquakes, and are almost hidden by the poplar, willow and fruit trees which surround them and line the broad streets. Its population in 1926 was 312,811. It has cotton-cleaning factories, makhorka-tobacco factories, a leather, machinery and cellulose industry, and sawmills; there is a municipal electricity, water and tram service. Much fruit and agricultural produce are grown in the oasis. The population is mixed, Russians, Sarts and Uzbeks predominating. Under the new régime efforts have been made to raise the status of women and a woman's co-operative store now exists in the town with a membership of about 600 Uzbek and Tatar women. The town has a good library, a museum which includes a collection of Graeco-Bactrian coins, and a Teachers' training college.

TASHKURGHAN or **KHULM,** a khanate and town of Afghan Turkestan. The khanate lies between Kunduz and Balkh. The ancient town of Khulm stood in the Oxus plain, surrounded by orchards of famous productiveness; but it was destroyed by Ahmad Shah Abdali, who founded Tashkurghan in the middle of the 18th century, and took all the inhabitants away from Khulm to populate it. Ancient Khulm is now only a mass of ruins; but Tashkurghan, lying two or three miles to the south of it, has become the great trade-mart of Afghan Turkestan. At Tashkurghan the caravans from India and Bokhara meet, and from here the merchandise is distributed.

TASMAN, ABEL JANSZOON (*c.* 1603–1659), the greatest of Dutch navigators, the discoverer of Tasmania, New Zealand, the Tonga and the Fiji Islands, and the first circumnavigator of Australia, was born at Lutjegast in Groningen, about 1603. In 1634 we first meet with him in the East Indies, sailing from Batavia (Feb. 18) to Amboyna. After a short visit to Holland he was again in Batavia in 1638. On June 2, 1639 Tasman, with Matthew Quast, was despatched by Antony Van Diemen, governor-general of the Dutch East Indies, on a voyage to the north-western Pacific, in quest of certain "islands of gold and silver," supposed to lie in the ocean east of Japan. On this voyage Tasman and Quast visited the Philippines and improved Dutch knowledge of the east coast of Luzon; they also discovered and mapped various islands to the north, apparently the Bonin archipelago. Sailing on to N. and E. in search of the isles of precious metals,

they ranged about fruitlessly in the northern Pacific. In October the navigators decided to return, and, after touching at Japan, anchored at the Dutch fortress-station of Zeelandia in Formosa on Nov. 24, 1639. After this Tasman was engaged in operations in the Indian seas (sailing to Formosa, Japan, Cambodia, Palembang, etc., as a merchant captain in the service of the Dutch East India Company) until 1642, when he set out on his first great "South Land" expedition Several Dutch navigators had already discovered various portions of the north and west coasts of Australia (as in 1605–06, 1616, 1618–19, 1622, 1627–28, etc.), but Tasman now first showed that this great South Land was an island

Van Diemen's Land and New Zealand.—Sailing from Batavia on Aug. 14, 1642 with two vessels, the "Heemskerk" and "Zeehaen," and calling at Mauritius (Sept 5 to Oct. 8), Tasman sailed first S., then E, almost seven weeks, and on Nov. 24 sighted (in 42° 25′ S., as he made it) the land which he named *Anthoonij van Diemen's landt* after Van Diemen, now called Tasmania. He coasted its southern shores, and, running up Storm Bay, anchored on Dec 1, in Frederick Henry's Bay, on the east coast of Tasmania. There he hoisted the Dutch flag. Tasman then steered E. for the Solomon Islands, and on Dec. 13 discovered a "high mountainous country," which he called *Staten landt* ("Land of the States," *i e*, of Holland, now New Zealand). Tasman believed the newly discovered land to form part of the same great antarctic continent as the other *Staten landt* which Schouten and Lemaire had sighted and named to the east of Tierra del Fuego. He anchored on Dec. 18 in 40° 50′ S., at the entrance of a "wide opening," which he took to be a "fine bay" (Cook's Strait). He gave the name of *Moordenaars* (now *Massacre*) *Bay* to this spot, where several of his men were killed by the natives (Dec. 19). He then sailed along the south shore of Cook's Strait, but without discovering the full extent of the strait here dividing New Zealand into two main islands Returning westward he then coasted the west side of the North Island, till, on Jan. 4, 1643, he reached the northern extremity of New Zealand.

Thence he bore away to N.N E and on Jan. 19–25 he discovered various islands of the Tonga or Friendly group. Here the ships provisioned, for the first time since leaving Mauritius. Thence Tasman steered N and W., reaching on Feb. 6 the eastern part of the Fiji archipelago, which he called Prince William's Islands and Heemskerk's Shoals. He reached the western extremity of New Guinea on May 18. He arrived at Batavia on June 15, 1643 after a ten months' voyage.

Second Voyage.—The materials for an account of Tasman's important second voyage in 1644 are scanty. He was instructed to obtain a thorough knowledge of Staten Land and Van Diemen's Land, and to find out "whether New Guinea is a continent with the great Zuidland, or separated by channels and islands," and also "whether the new Van Diemen's Land is the same continent with these two great countries or with one of them" In this voyage Tasman had three ships under his command, the "Limmen," "Zeemeeuw" (or "Meeuw"), and "Brak" (or "Bracq"). He coasted the south-west coast of New Guinea; he mistook the western opening of Torres Straits for a bay, but explored (and perhaps named) the Gulf of Carpentaria: for the first time the coast-line of this great bay was mapped with fair accuracy. Though preceded by Jansz (1606) and Carstensz (1623) on the east shore of the gulf as far as 17° S, Tasman first made known the south, and most of the west, coast. Beyond this he explored the north and west coasts of Australia as far as 22° S., and established the absolute continuity of all this shore-line of the "Great Known South Continent"; his chart gives soundings for the whole of this coast. Tasman's achievements were coldly received by the Dutch colonial authorities, but on Oct. 4, 1644 they rewarded him with the rank of commander (he had frequently enjoyed the use of the title already). He was also made a member of the Council of Justice of Batavia. He was a member of the committee appointed on April 18, 1645 to declare a truce between the Dutch East India Company and the viceroy of Portuguese India. In 1647 he commanded a trading fleet to Siam, and in 1648 a warfleet sent against the Spaniards of the Philippines (May 15, 1648, to January 1649). By 1653 he had quitted the company's service. He died probably before Oct. 22, 1659, and certainly before Feb. 5, 1661.

See R. H. Major, *Early Voyages to . . . Australia* (London, Hakluyt Society, 1859), especially pp. xciii.–cii., 43–58 (here are printed the instructions for Tasman and his colleagues on the voyage of 1644); G. Collingridge, *Discovery of Australia* (Sydney, 1895), especially pp. 238–40, 279–80; and, above all, J. E. Heeres and others, *Tasman's Journal . . . facsimiles of the original MS. . . . with . . . life . . . of . . . Tasman*, etc. (Amsterdam, 1898)—here the *Life of Tasman*, with its appendices, is separately paged (163 pp). *See* also *Aandeel der Nederlanders in de Ontdekking van Australië*, 1606–1765 (in Dutch and English, Leyden and London, 1899), especially pp. vi., viii, xii.–xv., 72; the valuable summary of the voyage of 1642–43 in the anonymous *Account of several late Voyages and Discoveries* (beginning with Sir John Narborough's), London, 1711, with sub-title, *Relation of a Voyage . . . of Captain Abel Jansen Tasman* (originally extracted from his journals by Dirk Rembrantse in Dutch, published in English in Dr. Hook's collections); also *The Discovery of Van Diemen's Land in 1642*, by James Backhouse Walker (Hobart, 1891).

TASMANIA, a State of the Commonwealth of Australia consisting of one large and numerous smaller islands, the largest of which, King, Flinders and Cape Barren Islands, lie in Bass Strait (total area, 26,215 miles—roughly that of Scotland—forming 0·88% of the area of the Commonwealth). The island of Tasmania extends from about lat 40° 40′ S. to lat. 43° 40′ S, is of a maximum length (N.–S.) of 180 m. and breadth (E.–W.) of 190 miles, and has a shield-shaped general outline tapering southwards It lies upon the main continental platform and at various periods formed part of the continent to its north. Bass Strait, though some 140–150 miles wide, is relatively shallow so that Tasmania is linked to the mainland by a submarine ridge carrying only 30–40 fathoms from which rise the groups of islands mentioned above. The latest severance of Tasmania is probably geologically recent and a rise of *c.* 200 ft.—or a corresponding fall in sea-level—would reunite it to the mainland It is, in fact, essentially a portion of the eastern highland belt of Australia (*see* AUSTRALIA: *Geomorphology*) and has the same general physiographic character modified, to some extent, by climate Subjected to repeated strains and stresses, and also to active denudation, throughout its history, the island-mass has assumed the character of an extremely irregular upland block, or group of blocks, with generally flattened tops but steep, and often precipitous (step-faulted) sides—*cf.* the term "tiers"—and possessing several coastal, and also some inland, lowlands in which crustal oscillations have produced features of both emergence and of submergence. The nearness in time of some of the most influential of these movements is proved by the freshness and sharpness of many of the forms (*e g.*, "drowned" coastal features, valley gorges, waterfalls and generally ungraded stream courses), by the signs of dislocated drainage, and by the general irregularity, and even wildness, of the topography. The extensive and varied igneous intrusions—Palaeozoic granites and serpentine, Cretaceous diabase, Tertiary basalts, etc.—evidence the intensity of the movements, while weathering has flattened, but also in part, by means of differential erosion, diversified the surface.

Physiography.—Several divisions may be distinguished. (i) The south and west are occupied by a broad belt of highlands presenting abrupt irregular fronts to the west and north. They are composed mainly of very ancient sedimentary rocks (Pre-Cambrian—Palaeozoic schists, quartzites, slates, sandstones and limestones) much intruded by granite and other igneous formations The general surface level rises to some 4,000 ft. with many summits approaching 5,000 ft. (Cradle Mountain, 5,069 ft.), but the incision of streams and the cutting of deep valleys and gorges (King River, 3,000 ft. deep, and *cf.* the valleys of the Arthur, Pieman, Gordon Rivers) has given rise to a wild, inaccessible, and little known landscape, with some lakes and forests, much poor and sterile rock and soil, but possessing great actual and potential mineral wealth. (ii.) The Central (Lake) Plateau, only partly dissevered from the above, consists mainly of Mesozoic rocks (Permo-Carboniferous) and slopes down from a general level of 3,500 ft in the northwest to lower levels in the southeast, in which direction it is drained by the streams of the Derwent system. To the north and northeast it presents a towering es-

carped front ("tiers") with individual elevations of over 4,000 ft. fashioned mainly out of igneous (diabase) intrusions. The rocks contain some oil shale and coal, but for the rest supply only grasslands. The heights which flank the central east coast are a portion of this formation, being severed only by the Macquarie-Coal River depression (elevation 660 ft. near Tunbridge). (iii.) The northeast highlands, though detached from the central massif by the broad Tamar-Esk depression, resembles it in being a plateau with levels rising to 3,000–4,000 ft. The Palaeozoic sediments have been penetrated by igneous intrusions of various dates and composition (granite, diabase, basalt), the harder of which form great bosses (Ben Lomond, highest elevation in the island, 5,160 ft.). They constitute a group of wild and mineralised mountain-blocks towering above the adjoining lowlands. (iv.) The northern lowlands a down-faulted area fronting Bass Strait and broadest in the northwest, consist substantially of the same rocks as the highlands behind (pre-Cambrian schists, Palaeozoic slates, sandstones, etc.) and, besides rich deposits of metallic ores, include valuable limestones, oil-shales and coal. Many of these rocks yield infertile soils, but the great basalt (Tertiary) flows which characterise this area redeem this quality, and these lowlands, with their irregular terrain and diversified potentialities form one of the richest regions. (v.) The east and southeast lowlands are even more irregular, and are worked out mainly in Mesozoic (Triassic–Jurassic) strata which contain coal. Diabase and older rocks form irregular, rough and infertile ranges, spurs and platforms over considerable areas, but the later strata yield soils useful for pasturage and cultivation.

Lakes are an especial feature of the Tasmanian highlands, and especially of the central plateau. Here, at an elevation of about 2,500 ft., the heavy rainfall is held up in impervious (diabase, etc.) rock-basins, and elsewhere (*e.g.*, in the west) are lakes of glacial origin. Great Lake (alt. 3,800 ft.) is 15 miles long and its natural depth was only 20 ft. It has importance in connection with a great hydro-electric supply scheme.

The *coast-line* (900 miles) receives its special character from recent subsidence, though there has been a still later but smaller elevation. Where the coast runs parallel to the grain of the highlands it is mostly closed (*e.g.*, on the west) and presents few good openings. On the northeast and southeast, on the other hand, are many curious features of submergence (*e.g.*, Freycinet and Tasman's peninsulas) and also some fine "drowned valley" harbours (Tamar, Derwent, *see* LAUNCESTON, HOBART) (*v. inf.*).

Climate.—Tasmania lies in the southern temperate zone in the track of the east-moving cyclonic systems ("lows"), while no part is far removed from the sea. Hence its climate is cool, equable and moist, somewhat resembling that of southwest England and Ireland. Like these, too, its weather conditions are exceedingly variable—hardly four consecutive days showing the same conditions—but in its case there is added to this variability an extraordinary local diversity due to the irregular and sharp-cut topographical features. Thus there is strictly no general climate of Tasmania, but, within limits, temperatures, and particularly rainfall, show remarkable ranges (*e.g.*, 130 in. at Lake Margaret on the west coast; 18 in. at Antill Ponds in the east midlands). Broadly speaking temperatures range from 65° F in summer to 45–50° F in winter, the east coast having temperatures in general *c.* 4° above those of the west coast owing to the influence of warm (north) and cool (south) sea-currents respectively. Rainfall is greatest in the west, where the highlands force precipitation from the moist westerly winds (40 in. av. ann. along the coast, rising to 60 in., and to 140 in. in the central northwest, with a late-winter maximum (*e.g.*, Queenstown: 100 in.; Aug., 10 in.; Feb., 4 in.). The northeast highlands also receive 40–80 in., but the eastern and central lowlands are in the "rain-shadow" of the western heights and receive some 20 in. more or less with a maximum in spring and summer when southeast winds blow in with rain. (*See* also LAUNCESTON, HOBART.) It is the cool and moist climate of Tasmania which lends it that relatively verdant and garden-like character which is such an attraction to Australians from hotter and drier latitudes.

Vegetation.—The natural vegetation was one of the finest and, potentially, the most valuable in the Commonwealth though its natural riches have been largely dissipated. The chief controlling factor appears to be rainfall—or rather, availability of moisture. Thus the beech forests—so-called "myrtle"—which are peculiar to Tasmania are found in various separate areas but always where the av. ann. rainfall is over 50 in. Eucalypts form the bulk of the forests in areas of intermediate rainfall and range from swamp and blue "gums" in the lower river-flats to the "snow" or "mountain" gum on higher slopes. Some of the "pines" (Huon, "celery-top," etc.) are also denizens of the lower and wetter valleys, *e.g.*, in the southwest. The "wetter" forests have also often a dense and almost impenetrable undergrowth (tree-ferns, laurels, etc.). In the drier "rain-shadow" lowlands of the east and centre the forests become thinner—though the trees tend to become individually finer—and a type of wooded "park" or grass-land prevails. The wind-swept plateau-tops carry little but stunted scrub, grasses, and bog and moorland vegetation merging in places into "alpine," and the lower hills which lie along and immediately behind the west coast, with their relatively light rainfall (20–40 in.) are matted over with the strange and impassible "horizontal" (*bauera*) scrub. The western mountains and valleys still contain fairly large forest patches (*e.g.*, the fine eucalypt forest of the Huon Valley), and the northeast also is well clad. In the lowlands and on the more accessible slopes the forests have been largely destroyed or wastefully depleted for their valuable contents. Commercially useful timber is supplied by many of the gums—blue, yellow (cider), swamp and stringy gums, peppermint, etc.—by the soft-wood pines, the beech, the blackwood of the northern basaltic slopes and valleys and also by the acacias (*e.g.*, the "black wattle" supplying tanning bark). Tasmania has a relatively large extent of forested land (1,500,000 acres, nearly 9% of total area). But, from the scientific forester's point of view, the forests are not as valuable as might appear. There were (1926) only 176,000 ac. of reserved forests, or, with timber and fuel reserves, 1,817,200 ac.

General Economic Aspects.—The extraordinary diversity of soil, climate, and of topographical feature within even a quite restricted area has given to Tasmanian land development a sporadic and somewhat "patchy" nature. This, and the very large extent (about ⅓) of broken and uncultivable terrain, has prevented the growth of large and simple types or areas, such as, *e.g.*, the wheat belt in Australia, and has rendered difficult any large-scale unified economic organization.

Mining and Metallurgy.—If Tasmania's mineral output is not relatively large it is large in proportion to the area of the State. The island contains some notable individual deposits and its reserves are also probably considerable, much of the country being as yet inadequately prospected. The minerals fall into two main classes: (a) *metallic minerals* occur chiefly in the older rocks of the western highlands where the extensive igneous activity has led to mineral concentrations. In the central west the Queenstown-Gormanston area has been developed, under conditions of extraordinary physical difficulty, upon a large scale, outlet being chiefly by Macquarie Harbour (Strahan, Pillinger). Northwards from this are the Zeehan-Dundas, Read-Rosebery, Waratah, Mt. Bischoff and other areas. Many of these mines produce varying quantities of silver, lead, copper and gold, partly as a by-product, *e.g.*, in copper refining. The copper is produced almost entirely by the Mount Lyell Mining and Railway Company which owns extensive workings, railway lines, electric (power and light) supply schemes (Lake Margaret). The output of this Company's mines in 1927–28 was 7,060 tons copper, 121,456 oz. silver, 2,360 oz. gold; the year's profits amounted to over £200,000, the liquid assets are valued at £1,043,000. Mount Bischoff is still noted for tin, while the Read-Rosebery zinc reserves are estimated at over 2,500,000 tons. In addition valuable osmiridium alluvial deposits occur along the west coast. The similar rock formations of the north, north-east and east contain gold (Beaconsfield, Lefroy, Lisle, Mathinna, Mangana) but more important is tin, the bulk of the Tasmanian output coming from the north-eastern fields (Gladstone, Derby, Branxholm, Ringarooma) and also from the east (St. Helen's, etc.), while a rich deposit

has also been discovered on King Island. Tasmanian iron reserves are estimated at 100,000,000 tons; the ore occurs in the ancient rocks of the west and north, notable deposits being at Rio Tinto (Savage River on the west coast: about 50,000,000 tons) and at Burnie where the Blythe River has cut through a deposit of 17–30,000,000 tons. The iron ores are as yet little exploited (b) *Non-metallic minerals* consist chiefly of coal, oil-shales, limestones, and pottery clays Coal (125,000,000 tons, actual, 123,000,000 probable, reserves) occurs in the Permo-Carboniferous, Trias-Jura and Tertiary strata along the north and east coastal areas and is increasingly mined around St. Mary's, in the Mersey Valley, etc. In the northern coastal areas occur large deposits of oil-shales, while limestones and clays in great quantity occur there and elsewhere The shales are as yet little worked, but the limestones and clays form the basis of the potentially important cement industry of Maria Island, etc., the limestones of Melrose are exported through Devonport for fluxing purposes to New South Wales (*see* BROKEN HILL), those near Hobart (*q.v*) are used for the carbide industry (1926: £68,400), and the clays are also used for tile, etc, manufacturing (*e.g.*, near Launceston). Metal concentrating and refining is conducted on a large scale on the Zeehan and Mount Lyell areas, but Mount Bischoff ores are smelted at Launceston (*q.v.*). The important Electrolytic Zinc Company's works at Risdon (*see* HOBART and BROKEN HILL) recovered (1926) 41,840 tons zinc (£1,428,000) and cadmium valued at £27,750 from Broken Hill ores (exclusive of Tasmanian concentrates treated). The Mount Lyell Mining and Railway Co has also engaged in the production of superphosphates, sulphuric acid, etc. As elsewhere in Tasmania the growing success of mining, metallurgical, etc, industries is due to hydro-electric power.

Timber, Fruit, etc.—Tasmania's saw-mill output (1925–26) was 53,600,000 super ft. (exports: 42,600,000 = £534,000). Recent discovery of the high value of Australian hardwoods for making paper-pulp has led to the establishment of a promising new industry which, able to absorb poorer timbers and "offal" formerly wasted, has, allowing for re-growth, unlimited reserves The cultivation of imported soft-wood species also holds out promise. Fruit-growing in Tasmania has progressed as over-sea markets have become available

Agriculture and Dairying.—The products of arable agriculture are characteristically oats, barley, potatoes and fodders. Tasmania was once the granary of Australia, but the uncertainty and dampness of the native climate, together with the competition of the later-developed and more suitable continental wheat-lands, have discouraged home production. A little is grown near Launceston and Hobart under the influence of the milling industry there (*cf.* the slight rise in recent years: 1924–25: 13,000 ac., 231,000 bu; 1927–28: 28,000 ac, 672,000 bu.), but in general Tasmania tends to import wheat and similar products. Her position opposite the great port and market of Melbourne—and more remotely and occasionally, that of Sydney—greatly aids this process of specialisation Oats, barley (malting), hay (chaff), pulses, potatoes—and also dairying with its associated pig-rearing, bacon-curing, cheese and butter making—have in fact a distribution clearly influenced by climate, soils and commercial position. The central northern lowlands—from Deloraine, through Westbury, Longford, Evandale, to Lilydale may be said to centre on Launceston which is both a market and exporting centre. The 15 mile wide strip of fertile coastal lowlands which stretches north-west to Stanley, backed by a similar belt of pastoral country and, beyond this, by timber areas, finds an outlet in such ports as Ulverstone, Penguin, Burney.

Pastoral Industries.—As more intensive forms of land utilisation have progressed, the pastoral industries have tended to decline, especially as in Tasmania there is small room to move away as settlement advances. To some extent, however, this tendency has been checked by specialisation, "meat" cattle, for example, being replaced by dairy herds, while in the case of sheep, careful local adaptation has led to survival, *e.g.*, of "utility" (meat-wool) types as elements in a mixed farming régime. Notable, also, is the achievement of several long-established sheep-breeding families in rearing high-class strains.

Sheep—The whole of the west of the island is too wet, or too wild, for sheep, and these are confined mainly to the areas with 30 in. or less av. ann. rainfall which comprise the south-east ⅓ of the island, relatively few being scattered along the north coastlands. The greatest concentrations are in the upper and central Macquarie River basin and in the northern hill-lands of the Derwent-Coal basin ("The Midlands"). The Longford, Evandale and Oatlands districts show densities of 300 per sq. mile, and here the sheep fit into the farming rotation and are mainly marketed as meat, fresh (Launceston, Hobart) or refrigerated (export). In the north other cultivations (*v. sup*) are more profitable. In the poorer and rougher eastern hill and coast lands fewer are kept, but the central highlands provide good summer grazing-grounds for sheep from the adjoining districts to the east. *Cattle,* apart from dairy cattle (*v. sup.*), are decreasingly important, but they are found in the rougher lands around the borders of, and between, the better farming areas along the north and east and more particularly in "the midlands" (*i.e.*, northern Derwent-Coal River hill-lands) and here tanning assumes local importance

Manufacturing Industries; Power Supply.—These have grown up upon the basis of the primary producing industries and are still often locally associated with them: extraction and refining of metals; sawmilling; making of jams and preserves, dairy products, bricks, tiles and pottery; tanning, etc. (*v. sup*). Secondary are the chemical, cement, carbide and electrode industries; making of furniture, agricultural implements, etc. A new tendency, however, has now appeared, namely for industries of a larger and more derivative type to concentrate in Launceston and Hobart (*qq.v*). As this tendency develops greater strength, the manufacture of chemical products, cement, iron, paper, artificial silk, woollen and other textiles may be expected to assume considerable proportions The reasons lie partly in the presence of raw materials, partly in the favourable position of Tasmania with relation to (chiefly) Victoria, New South Wales and South Australia, but mainly in the fact that Tasmania, along with a cool climate, possesses reserves of water-power The *water-power* resources are the property of the State which develops them and sells power in bulk to large consumers and municipalities, though it also retails power to consumers in Hobart. The Great Lake scheme (63,000 h.p) is completed. Advantage has been taken here of the Great Lake, whose area has been increased to 60 sq miles and depth to 55 ft. by means of a dam, and also of a difference in level of 1,250 ft between the parallel valleys of the Shannon and the Ouse. The Shannon scheme, adjacent (13,000 h.p.), is under construction Launceston (*q v*) and its district, as well as Hobart, is supplied from the Great Lake system, other systems being the Lake Margaret-Zeehan, Zeehan-Rosebery (under construction), Country District and North-west Coast Service So far only 52,000 h p has been utilised, the Electrolytic Zinc Works (Risdon) consuming 35,000 h.p.; the Carbide works. 3,500; Hobart, 8,500; Launceston, 3,000. The further reserves of Tasmania are estimated at over 500,000 continuous h.p. Besides the State schemes the Mount Lyell Mining and Railway Co. can supply 8,000 continuous h p, and there are numerous smaller mining and municipal supplies.

The coasts abound in good natural harbours—though some are exposed and not very useful—but the main sea traffic centres on Hobart, Launceston, on the north coast ports and on those of Macquarie Harbour.

See G L. Wood, *The Tasmanian Environment* (1923).

Statistical Summary: *Area and Occupation.*—26,215 sq. miles (= 16,778,000 acres) = 0·88% of the Commonwealth, wholly in temperate zone. Coast-line: 900 miles = 1 mile per 29 sq miles of land surface Of the total area 6¼ million acres had been alienated in 1925; over 8 million acres were unoccupied; pastoral leases, 1,685,000 acres; timber leases, 285,000 acres. Of private holdings 87% were 1–500 acres, and there were 4 holdings of 50,000–100,000 acres and over

Population (1927/8): 215,862 (males, 107,036; females, 108,826) = 8·2% per sq. mile; 3·5% of total population of Commonwealth; 1921–26: total natural increase, 90,147 and loss by migration, 48,293; 1924–5–6: net decreases of 1,235, 807, 2,278

respectively. Metropolitan: Hobart and suburbs (54,890 acres), 55,000 (1927/8) = 25·67% of total population.

Occupations (Census, 1921: total population 213,780). *Breadwinners* 39·19%, allocated thus: industrial, 10·55%; agricultural, 9·98%; commercial 4·79%; professional and domestic (each), 3%; transport, 2·84%; mining, 1·59%; pastoral, ·87%.

Production (net value): agricultural and pastoral (1922/3–1925/6), *c.* £4,400,000; manufacturing (1924–6), £3,400,000. (Net figures, on new basis, not yet available for other industries.)

Mining (gross value of metal contents of ores produced, 1926): Total, £1,574,000 copper, £455,000; tin, £323,000; lead and zinc (each), £183,000; silver, £98,000; coal, £90,400 (102,000 tons); osmiridium, £62,000; limestone, £54,000; gold, £18,000. In the case of copper, lead and tin these figures fairly represent the general level of annual production during 1919–26; zinc production (Tasmanian-mined ore) shows a great rise, that of coal a steady rise, that of silver, osmiridium, wolfram, great fluctuation during the same 8 years. Gold production (1927), £20,650.

Trade, Commerce, Communications.—Trade: Total (1925–6) £17,155,000 (£80·8 per caput). *Exports*: £8,704,000 (Interstate: £6,125,000; overseas—*i.e.*, outside the Commonwealth—£2,579,000). Metals: £2,704,000 (zinc, including imported ores treated, £1,589,000); fruits, £1,000,000; jams and other prepared foods, £800,000; potatoes, £600,000; dairy produce, £117,000; wool, £816,000; hides, etc., £400,000; timber, £534,000.

Imports: £8,451,000 (Interstate: £6,932,600; overseas, £1,518,000). Food and drink: £1,780,000; metals and machinery, £1,570,000; clothing, etc., £1,529,000.

Shipping (entered and cleared): 2,000–2,500 vessels, 1·5–2·75 million tons (net).

Ports: Total trade (1925/6): Hobart: £9,390,000 (54·7% of total State); Launceston, £4,733,000 (27·6%); Burnie, £1,089,000 (6·3%); Devonport, £863,250 (5·0%).

Railways: Government lines (1926/7): 658 miles (633 miles, 3′ 6″; 25 miles, 2′ gauge). Private (1925/6): 143 miles. Profit on working: (State lines): £41,150; Net loss: £12,000 = 3·76% on capital cost.

Finance.—(1926/7) Revenue: £3,040,220 (£14. 3. 2 per caput); expenditure, £2,855,077 (£13. 5. 11). Public debt (net): £23,196,814 (£111. 8. 7) paying interest at 4·907%. Total taxation (State, Commonwealth and municipal): £14. 8. 0 per caput. Banks (private) (1926): cash reserves: £1,499,000; deposits, £6.145,600.

Social Conditions.—Education: (1925) State schools: 523 Primary, 5 High; 1,315 teachers; average attendance, 32,300. Private schools: c. 6,200 pupils. State expenditure on education: primary: £8. 13. 5 per scholar attending; higher, £16. 4. 11. Total expenditure on education, exclusive of buildings, £297,130 (£1. 7. 5 per caput of population).

Bank deposits: private banks (1926) £6,145,600; savings banks (1927/8): £5,149,798 (142,010 depositors; £36. 5. 3 per depositor). Expenditure on hospitals and charities (1925/6): £178,500 (16s. 5d. per head of population). (O. H. T. R.)

History.—Tasmania, or, as it was originally called, Van Diemen's Land, was discovered in 1642 by the Dutch navigator Tasman (*q.v.*), who named the territory after his patron, Van Diemen. In the 18th century the island was visited by French and English explorers, including Capt. Cook in 1777. The news that the French explorer, Baudin, had surveyed the south of the island in 1800 stimulated the British to forestall the French. In 1802 the "Cumberland," a small schooner, landed at King's island in Bass strait, and in 1803 Lieut. Bowen was sent by Governor King of New South Wales to form a settlement on the south coast of Van Diemen's Land. In 1807, Col. Paterson occupied Port Dalrymple on the north side of the island. During the same year Col. Collins, who had failed in an attempt to colonize the shores of Port Phillip, transferred his soldiers, convicts and officials to the neighbourhood of Hobart, and was appointed commandant of the infant settlement. The difficulties of the settlers were increased by the hostility of the blacks. The first collision took place at Risdon, a few days after the landing of Lieut. Bowen's expedition, and for this the white settlers were entirely responsible. Hostilities between the races were incessant from 1802 till 1830. In 1831 George Robinson induced the remnant of the blacks to leave the mainland and take refuge, first in South Bruni and subsequently in Flinders island, their numbers having then diminished from 5,000, the original estimate of the aboriginal population, to 203. The last pure-blooded Tasmanian died in 1876, at the age of 76.

The growth of population was extremely slow, and in 1808 a census showed that there were only 3,240 people on the island, all told. Soon settlers began to arrive, and as their number in the colony increased, an agitation arose for more political freedom and improved administration, in consequence of which, in 1822, courts-martial were replaced by courts of justice, and in 1825 the colony was made independent of New South Wales, Col. Arthur being appointed governor. In 1828 the Van Diemen's Land Company commenced sheep-farming on a large scale in the north-west district of the island under a charter granted three years before, and in 1829 the Van Diemen's Land Establishment obtained a grant of 40,000ac. at Norfolk Plains for agriculture and grazing. In 1834 Portland bay, on the mainland of Australia, was occupied by settlers from Van Diemen's Land, and in 1835 there was a migration, large when compared with the population of the island, to the shores of Port Phillip, now Victoria. At that date the population was 40,172, a large proportion being convicts, for in four years 15,000 prisoners had been landed. The colony was prosperous, but the free settlers were not at all satisfied with the system of government, and an agitation commenced in Van Diemen's Land, as well as in New South Wales, for the introduction of representative institutions and the abolition of transportation. This system was abolished in New South Wales in 1840, and in the island, which in the interim had been the receptacle for convicts from the United Kingdom, India and the colonies, in 1853. In the same year representative institutions were introduced and the colony was renamed Tasmania: three years later responsible government was granted.

The discovery of gold in Victoria had the effect of causing the value of exports to that colony to rise from £665,790 in 1851 to £1,765,316 in 1853, while the population diminished, young men and women of all classes migrating to the Australian mainland. In the sixties Tasmania embarked upon a new period of prosperity owing to the discovery in its western half of coal, in 1850, and gold in 1852. Later political history, until the colony became in 1901 part of the Commonwealth of Australia, was not important. The colony has a citizen defence force of about 1,700 officers and men, forming part of the Australian army; it furnished contingents both in the South African War and the World War.

See J. Fenton, *A History of Tasmania* (Hobart, 1884); H. Ling Roth and M. E. Butler, *The Aborigines of Tasmania* (2nd ed., Halifax, 1899); Royal Society of Tasmania, *Papers and Proceedings* (Hobart). *See* also AUSTRALIA.

TASMANIANS. The Tasmanians, who are now extinct, were of medium height, had black to dark brown skins; woolly hair; heavy brows; longish, oval or pentagonal, flattish and small sized (cranial content) heads; short broad noses and large teeth.

Culture.—They were food-gatherers, expert hunters and trackers of game, nomads, moving in small groups of the family type, with very little government but recognising the areas belonging to other groups as reserved and not to be interfered with except on risk of war. Hereditary or permanent chiefs do not seem to have been found. No marriage ceremony is recorded and there seems ground for holding that they were polygynous. They are typical representatives of the Early Stone and Wood Age. The stone implements are very crude in form and finish (akin to Mousterian products) and were made of phthanite, a fine grained sandstone. Fire was made with the groove and saw or with the drill. Stones with black and red bands were used for tallies or mnemonics for absent friends. All have been lost and their exact significance is not quite clear. They made rough drawings on bark, with charcoal, ornamented themselves, using red ochre for the hair and wore shell necklaces, fillets of gay flowers, or festoons of showy berries. Huts and wind-breaks were used as shelters. Skins were thrown over the back against rain but otherwise they were naked. Scarification was practised and they

rubbed themselves with powdered charcoal and red ochre. They greased their bodies against rain. They made rafts generally of the bark of some species of Eucalyptus, which was rolled up into cigar shaped bundles, three going to a raft, broad in the middle and tapering to a point at each end. These were good fair weather craft but dangerous in storms. They used their spears for fishing but had neither bow and arrow nor boomerang.

Language.—There were five dialects, classified on a geographical basis in two main groups as eastern and western. Enough remains to show that they were all related and were dialectical variations from a common archetype. The language is said to have been musical and soft, vowels being peculiarly full and round They had no *d, f, v, s,* or *z.* Words began generally with a consonant, *cr, pr* and *tr* being common, other combinations being rare. Words end with a vowel as a rule. Distinct forms were used for singular and for plural.

BIBLIOGRAPHY.—H. Ling Roth, *The Aborigines of Australia,* 1890, a careful and complete collection of earlier information which has been used by later writers. *See* also W. J. Sollas, *Ancient Hunters,* 3rd ed. 1924.

TASSIE, JAMES (1735–1799), Scottish gem-engraver and modeller, was born at Pollokshaws, near Glasgow, on July 15, 1735, and died in London on June 1, 1799. During his earlier years he worked as a stonemason until he removed to Glasgow to attend the academy established by the brothers Foulis, the printers, and became one of its most distinguished pupils Subsequently he visited Dublin and became acquainted with Dr. Quin, who had been experimenting in imitating antique engraved gems in coloured pastes. He engaged Tassie as an assistant, and together they perfected the discovery of an "enamel," admirably adapted by its hardness and beauty of texture for the formation of gems and medallions. Tassie went to London in 1766 After a hard struggle the beauty and artistic character of his productions came to be known. The empress of Russia commissioned a collection of about 15,000 examples; all the richest cabinets in Europe were thrown open to him for study and reproduction; and his copies were frequently sold by fraudulent dealers as the original gems He exhibited in the Royal Academy from 1769 to 1791. In 1775 he published the first catalogue of his works, followed in 1791 by two volumes quarto, enumerating nearly 16,000 pieces.

Tassie also executed many large profile medallion portraits of his contemporaries. They were modelled in wax and were then cast in white enamel paste, the whole medallion being sometimes executed in this material; while in others the head only appeared in enamel, against a background of ground-glass tinted by paper placed behind. At his death, in 1799, Tassie's works numbered about 20,000 pieces.

His nephew, WILLIAM TASSIE (1777–1860), also a gem-engraver and modeller, succeeded to the business. His portrait of Pitt, in particular, was very popular, and circulated widely. He bequeathed to the Board of Manufactures, Edinburgh, a valuable collection of casts and medallions by his uncle and himself.

See Gray's *James and William Tassie,* 1895.

TASSO, BERNARDO (1493–1569), Italian poet, father of Torquato Tasso (*q.v.*), was born at Venice on Nov. 11, 1493, of a noble family of Bergamo. He was attached to the service of the prince of Salerno, and married a Neapolitan lady, Porzia de' Rossi. When his patron came into conflict with the Spanish Government of Naples Bernardo was proclaimed a rebel and his property sequestrated. In 1556 his wife Porzia died under mysterious circumstances. Next year he entered the service of the duke of Urbino, and became a considerable figure in the literary circle of his court. He wrote a long, complicated and dull romantic poem in octave stanzas, entitled *Amadigi* (Venice, 1560). Bernardo died at Ostiglia on Sept. 4, 1569.

TASSO, TORQUATO (1544–1595), Italian poet, son of the preceding, was born at Sorrento on March 11, 1544. He was brought up at Naples, where he lived with his mother and his only sister Cornelia, and was educated by the Jesuits. He was a precocious child and famous in Naples for his learning when, at ten years old, he joined his father in exile in Rome. In 1557 he accompanied his father to the court of Urbino Torquato, a handsome and brilliant lad, now became the companion in sports and studies of the young heir, Duke Francesco Maria della Rovere. He met there many of the most famous scholars of the day, including Aldus Manutius and the critic Speroni. At Venice, whither his father went to superintend the printing of the *Amadigi* (1560), he found himself the pet and prodigy of a distinguished literary circle. He was then sent to study law at Padua, but his distaste for the subject led Bernardo to allow his son to exchange the study of law for that of philosophy and poetry at Padua, and then at Bologna. In 1561 he published some poems, and before the end of 1562 produced a narrative poem, *Rinaldo,* in twelve cantos which proposed to combine the regularity of the Virgilian with the attractions of the romantic epic. Tasso, who was still only 18 years old, sought to give the adventures of Roland a classic form. He was now famous. In 1565 he became attached to the learned court of Ferrara, at first in the service of the Cardinal Luigi d'Este.

The years between 1565 and 1570 seem to have been the happiest of Tasso's life, although his father's death in 1569 caused him profound pain. He was the idol of the most brilliant court in Italy. The princesses Lucrezia and Leonora d'Este took him under their protection. He was admitted to their familiarity, and there is some reason to think that neither of them was indifferent to him personally. In 1570 he travelled to Paris with the cardinal. Frankness of speech and a certain habitual want of tact caused a disagreement. He left France next year, and took service under Duke Alfonso II. of Ferrara. The most important events in Tasso's biography during the following four years are the publication of the *Aminta* in 1573 and the completion of the *Gerusalemme Liberata* in 1574 The *Aminta* is a pastoral drama of very simple plot, but of exquisite lyrical charm. It was represented at Ferrara in the summer of 1573, at the critical moment when modern music, under Palestrina's impulse, was becoming the main art of Italy.

The *Gerusalemme Liberata* occupies a larger space in the history of European literature, and is a more considerable work. Yet the commanding qualities of this epic poem, those which revealed Tasso's individuality and which made it a classic, beloved by the people no less than by persons of culture, are akin to the lyrical graces of *Aminta.* It was finished in Tasso's 31st year, and was read to the duke and to Princess Lucrezia in the summer of 1575.

As in the *Rinaldo,* so also in the *Jerusalem Delivered,* he aimed at ennobling the Italian epic style by preserving strict unity of plot and heightening poetic diction. He chose Virgil for his model, took the first crusade for subject, infused the fervour of religion into his conception of the hero Godfrey. But his own natural bias was for romance. Godfrey, a mixture of pious Aeneas and Tridentine Catholicism, is not the real hero of the *Gerusalemme.* Fiery Rinaldo, Ruggiero, impulsive Tancredi, and the chivalrous Saracens with whom they clash in love and war, divide our interest and divert it from Goffredo. The action of the epic turns on Armida, the beautiful witch, sent forth by the infernal senate to sow discord in the Christian camp. She is converted to the true faith by her adoration for a crusading knight, and quits the scene with a phrase of the Virgin Mary on her lips. Brave Clorinda, donning armour like Marfisa, fighting in duel with her devoted lover, and receiving baptism from his hands in her pathetic death; Erminia seeking refuge in the shepherd's hut—these lovely pagan women, so touching in their sorrows, so romantic in their adventures, so tender in their emotions, rivet our attention, while we skip the battles, religious ceremonies, conclaves and stratagems.

Tasso's self-chosen critics suggested every course but the right one, which was to publish the *Gerusalemme* without further dispute. Tasso, already overworked by his precocious studies, by exciting court-life and exhausting literary industry, now grew almost mad with worry. His health began to fail him. He complained of headache, suffered from malarial fevers, and wished to leave Ferrara. The *Gerusalemme* was laid aside in manuscript for a time. He opened negotiations with the court of Florence for an exchange of service. This irritated the duke of Ferrara, who feared that the Medici might get the coveted dedication of that already famous epic. Therefore he bore with the poet's humours. Mean-

while Tasso became the subject of delusions—thought that his servants betrayed his confidence, fancied he had been denounced to the Inquisition, expected daily to be poisoned. In 1576 he quarrelled with a Ferrarese gentleman, Maddalo, who had talked too freely about some love affair; in the summer of 1577 he was relating his sorrows once more to the princess Lucrezia, when he imagined a servant was listening and rushed on him, knife in hand. He was shut up in a room in the palace, and the duke then took him to his country seat of Belriguardo. The often told story, immortalized by Goethe, that a compromising *liaison* with Leonora d'Este came to light, and that Tasso agreed to feign madness in order to cover her honour, must be dismissed. The poet's own temperament and the critics of his *Gerusalemme Liberata* had aggravated his ill-health. He was now placed in a Franciscan convent at Ferrara. He escaped at the end of July, disguised himself as a peasant and went on foot to his sister Cornelia at Sorrento.

He seems to have found peace and healing with his sister, but after a time missed the court circle, and asked to return to Ferrara. There his old irritability returned. In the summer of 1578 he ran away again; travelled through Mantua, Padua, Venice, Urbino, Lombardy. In September he reached Turin on foot, and was courteously entertained by the duke of Savoy. Wherever he went, "wandering like the world's rejected guest," he met with the honour due to his illustrious name. But life was intolerable to him outside Ferrara. In February 1579 he returned at an ill-chosen moment. Alfonso was about to contract his third marriage, this time with a princess of the house of Mantua. The princesses did not want to see him. The duke was engaged. Tasso broke into terms of open abuse, and was sent off without ceremony to the madhouse of St. Anna. There he remained for seven years until July 1586. After the first few months of his incarceration, during which he was treated with the harshness then usual towards the insane, he obtained spacious apartments, received his friends, and went abroad attended by friends. Except for occasional odes or sonnets—some written at request and only rhetorically interesting, a few, like the famous canzone asking for the intercession of Lucrezia and Leonora, inspired by his keen sense of suffering and therefore poignant—he neglected poetry.

Long ago his papers had been sequestrated. Now, in 1580, he heard that part of the *Gerusalemme* was being published without his permission and without his corrections. Next year the whole poem was given to the world, and in the following six months seven editions appeared. The prisoner had no control over his editors; and from the masterpiece which placed him on the level of Petrarch and Ariosto he never derived one penny of pecuniary profit. The fame of the poem rapidly spread throughout Europe; within twenty years of its publication it was translated into English in the well-known version, itself a masterpiece, of Sir Edward Fairfax, *Godfrey of Bulloigne, or the Recoverie of Jerusalem* (1600). A rival poet at the court of Ferrara, Battista Guarini, undertook to revise and re-edit his lyrics in 1582. In 1585, two Florentine pedants of the Della Crusca academy declared war against the *Gerusalemme*.

In 1586 Tasso left St. Anna at the solicitation of Vincenzo Gonzaga, prince of Mantua. He followed his young deliverer to the city by the Mincio, basked awhile in liberty and courtly pleasures, enjoyed a splendid reception from his paternal town of Bergamo, and produced a tragedy called *Torrismondo*, the first sketch of which dates from 1574. But in the autumn of 1587 we find him wandering once more, through Bologna and Loreto to Rome, where he stayed in the house of an old friend, Scipione Gonzaga, now patriarch of Jerusalem. Next year he wandered off to Naples, where he wrote his unfinished poem on *Monte Oliveto*. In 1589 he returned to Rome, but fell ill. The patriarch in 1590 again received him. But Tasso's restless spirit drove him forth to Florence. The Florentines said, *"Actum est de eo."* Rome once more, then Mantua, then Florence, then Rome, then Naples, then Rome, then Naples—such is the weary record of the years 1590–94. We have to study a veritable Odyssey of malady, indigence and misfortune.

His health grew feebler and his genius dimmer. In 1592 he gave to the public a revised version of the *Gerusalemme*, called the *Gerusalemme Conquistata*. All that made the poem of his early manhood charming he rigidly erased. The versification was degraded; the heavier elements of the plot underwent a dull rhetorical development. During the same year a poem on the Creation in blank verse, called *Le sette Giornate*, saw the light.

In 1594 Clement VIII. and his nephew, Cardinal Aldobrandini of St. Giorgio, invited Tasso to Rome. There he was to assume the crown of bays, as Petrarch had assumed it, on the Capitol. Worn out with illness, Tasso reached Rome in November. The ceremony of his coronation was deferred because Cardinal Aldobrandini had fallen ill. But the pope assigned him a pension; and, under the pressure of pontifical remonstrance, Prince Avellino, who held Tasso's maternal estate, agreed to discharge a portion of his claims by payment of a yearly rent-charge. Fortune came too late. Before the crown was worn or the pensions paid he ascended to the convent of St. Onofrio, on a stormy April 1 in 1595. Seeing a cardinal's coach toil up the steep Trasteverine Hill, the monks came to the door to greet it. From the carriage stepped Tasso, the Odysseus of many wanderings and miseries, the singer of sweetest strains still vocal, and told the prior he was come to die.

He passed away on April 25, 1595, and the cell he occupied became a place of pilgrimage for his admirers. The last twenty years of his existence had been ineffectual. At the age of thirty-one the *Gerusalemme*, as we have it, was accomplished. The world, too, was already ringing with the music of *Aminta*. More than this Tasso had not to give to literature. But those succeeding years of derangement, exile, imprisonment, poverty and hope deferred endear the man to us. (J. A. S.; X.)

Bibliography.—The best edition of Tasso's works is that of Rosini 33 vols. (Pisa, 1821–32); C. Guasti has edited the prose works 2 vols. (Florence, 1875) and the letters 5 vols. (Florence, 1853). English translations of *Gerusalemme* include the often reprinted translation by Sir Edward Fairfax (1600) and that by J. K. James (1884). One of the earliest translations of the *Aminta* was that of Abraham Fraunce (1591); the latest is that by E. Grillo (1924). G. Grinnell-Milne has published *Tales from Tasso and other translations* (1909). *See* also Manso's *Vita* in Rosini's edition of the works; Serassi's *Vita* (Bergamo, 1790); Solerti, *Vita di Tasso* 2 vols. (Rome, 1895) and also his editions of *Le Rime di T. Tasso* 4 vols (Bologna, 1898–1902) and *Gerusalemme Liberata* 3 vols. (Florence, 1895–96); W. Boulting, *Tasso and his Times* (1907); E. Donadoni, *T. Tasso* 2 vols. (Florence. 1921) and A. D'Amato, *Studi sul Tasso e sul Manzoni* (Piacenza, 1924).

TATA, SIR DORABJI JAMSETJI (1859–), Indian capitalist, was born at Bombay on Aug. 27, 1859, being the elder son of the famous Parsee industrial pioneer, Jamsetji Nasarwanji Tata. Upon leaving Cambridge, he entered his father's business and pursued his father's great conceptions until they culminated in striking advances in Indian industrial development and also in the establishment in 1905 of the Indian institute of scientific research at Bangalore. *See* Tata Sons, Limited.

TATA, JAMSETJI NASARWANJI (1839–1904), Parsee merchant and philanthropist, was born at Nosari, in the state of Baroda, in 1839, and went as a boy to Bombay, where he was educated at the Elphinstone College. In 1858 he entered his father's office, and began a commercial career of the highest eminence, beginning with cotton mills at Bombay and also at Nagpur, and ending with the formation of a company to work the iron ores of the Central Provinces on modern principles. He also introduced a silk industry after Japanese methods into Mysore. But his greatest benefaction is the endowment of a research institute at Bangalore. He died at Nauheim, in Germany, on May 19, 1904.

TATA, SIR RATAN (1871–1918), Parsee financier and philanthropist, was born at Bombay on Jan. 20, 1871, the son of the famous Parsee merchant Jamsetji Nasarwanji Tata (*q.v.*). He was educated at St. Xavier's college, Bombay, and entered his father's firm. On the death of the elder Tata in 1904 Ratan Tata and his brother, Dorabji Jamsetji Tata (b. 1859), inherited a very large fortune, much of which they devoted to philanthropy and to the establishment of industrial enterprises. See Tata Sons, Limited.

In England he founded (1912) the Ratan Tata department of social science and administration at the London School of Eco-

nomics, and in the same year established a Ratan Tata fund at the University of London for studying the conditions of the poorer classes. He died at St. Ives, Cornwall, on Sept. 5, 1918.

TATAR REPUBLIC, an Autonomous Socialist Soviet Republic, created in 1920, in the Russian Republic and bounded on the south by the provinces of Ulianovsk and Samara, on the west by the Chuvash A.S.S.R. and the Marii Autonomous Area, on the north by Vyatka province and the Votyak Autonomous Area, and on the east by the province of Perm and the Bashkirian A.S.S R. Area 67,241 square kilometers. Pop. (1926) 2,622,890. The republic is drained by the Volga and Kama and their tributaries, the Vyatka, joining the Kama in the east, and the Svyaga flowing northwards to the Volga in the west. Forest—pine, fir and juniper in the north, and birch, ash, lime, alder, willow and elm in the south—occupies about 17% of the republic, and in the north there is some marsh land. Of the land favourable to cultivation, 78% is tilled, agriculture being the main occupation of the people Black earth is found in the south-west, along the valley of the Svyaga and in a few other places, the remaining soils being grey forest, clays and sands. The climate is continental, five months of the year having an average temperature below 0° C, and the rainfall averages 16 in per annum in good years, but may fail periodically, resulting in such famines as those of 1911 and 1921, these being caused by insufficient spring rain; summer and autumn rains are more reliable. The prevailing winds are from the south-west, and often bring dust storms that cover the crops In June and July thunderstorms with destructive hail are a frequent source of damage.

Agriculture and Industries.—These difficult conditions, giving harvests for export in some years and reducing the region to famine in others, are an indication of the need for more intensive forms of agriculture. Up to 1920 there was no many-field system and the peasants mainly used old-fashioned instruments. The tragic holocaust of the famine year was specially severe in the Tatar area, and since that time about 5% of the fields are being tilled on more intensive lines, and there has been greater care in the choice of seeds and crops. Attempts are being made to encourage maize, potato and beet cultivation, and to diminish the sowing of buckwheat, which gives a very unreliable harvest. Some better instruments are gradually replacing the traditional ones. In 1926 there was a good harvest and over 300,000 tons of grain were available for export. Rye (48·8%), and oats (19·2%) are the chief crops Others are buckwheat, millet, grasses, lentils, flax and hemp The mineral wealth is not great.

Factory industries are mainly centred on Kazan (*q v.*) which was the only town in 1926 with a population of over 16,000. The chief future for factory industry lies in food production, but this cannot be developed to an export industry until railway and road communication is improved The leather industry dates back to the Bolgar empire, and the Morocco and Russia leather of the Tatar Republic finds a ready market even beyond the U S.S R. The manufacture is at present mainly carried on in numerous small factories and in peasant artels. There is some flour-milling, two factories produce agricultural machinery, three work in hemp and jute and one in linen goods The present supply of wool is insufficient for factory production. Glass, bricks, lime, alabaster and silicate are produced. There are four printing presses producing Tatar magazines, papers and books In pre-war times the koustar or peasant industries of the region flourished. The Government is taking measures to restore these industries, since they are a means of giving the peasant sufficient income to prevent the wandering in search of employment that has been such a feature of Russia, and they also provide for the workless and landless peasant. Among the varied peasant products, sleighs, tarantasses and carts are famous and are in demand in Siberia. Tatar guitars, dulcimers and violins are noted.

Language and Education.—A great difficulty of the republic is its low rate of literacy, possibly 25% among men, certainly less among women. The position is difficult, partly because the budget of the republic at present shows a marked deficiency and school premises and materials are not available. The greatest difficulty, however, is the variety of languages. The Tatar population numbers 48·3%, Great Russians 43·1%, Chuvash 4·9%, Mordva 1·4% and various other nationalities 2·3%. Assimilation has hardly existed in the past and it is quite common for a village to have a group of Tatars in one section, of Finns in another and of Great Russians in another, each using its own language and following its own customs. Under the Tsarist régime education was mainly Russian. Since the foundation of the republic, Tatar is the official language of the administration and in 1925 there were many more Tatar schools, but the training of teachers is a difficulty, moreover the Tatar population is rural, and the greater proportion of the town population is Russian, and as there is a possibility of education in rural districts for about 30% of the children and in towns for about 70%, the problem is complex

History.—From the 5th century onwards there was a strong immigration of Bulgarians into the region; they formed an important khanate, Bolgari or Bolgary, 60 m. S. of Kazan being the centre; its ruins are still to be seen This kingdom reached its zenith in the 10th century, but was ruined by the Mongol invasion of the 13th century. Much intermixture between the Bolgars and the Mongols and also between local Finnish tribes has given the Volga Tatars a distinctive character. After the fall of the Golden Horde, these northern Tatars formed a khanate with Kazan as its centre, and there began the immigration into the region of refugee tribes, Mordva, Chuvash, Meschyeraks and Bashkirs. After the capture of Kazan in 1552, a policy of colonial Russian settlements on the Volga, with lines of forts to protect them from attacks by the natives was pursued. The problem facing the Tatar A.S S R is the establishment of co-operation among these varied elements. (R. M F)

TATARS (the common form Tartars is less correct), a name given to nearly three million inhabitants of the Russian empire, chiefly Muslim and of Turkish origin The majority—in European Russia—are remnants of the Mongol invasion of the 13th century (*see* MONGOLS), while those who inhabit Siberia are survivals of the once much more numerous Turkish population of the Ural-Altaic region, mixed to some extent with Finnish and Samoyedic stems, as also with Mongols. The name is derived from that of the Ta-ta Mongols, who in the 5th century inhabited the north-eastern Gobi, and, after subjugation in the 9th century by the Khitans, migrated southward, there founding the Mongol empire. Under the leadership of Batu they moved westwards, driving with them many stems of the Turkish Ural-Altaians towards the plains of Russia The present Tatar inhabitants of European Russia, contain very little admixture of Mongolian blood, but belong to the Turkish branch of the Ural-Altaic stock, only Batu, his warriors, and a limited number of his followers being Mongols, while the bulk of the 13th century invaders were Turks On the Volga they mingled with remnants of the old Bulgarian empire, elsewhere with Finnish stems, and with remnants of the ancient Italian and Greek colonies in Crimea, and Caucasians in Caucasus. The name of Tatars, or Tartars, given to the invaders, was afterwards extended to different stems of the same Turkish branch in Siberia, and even the bulk of the inhabitants of the high plateau of Asia and its N W slopes, described under the name of Tartary.

The Tatar inhabitants of the Russian empire formed three large groups—those of European Russia and Poland, those of Caucasus, and those of Siberia (1) The Kazan Tatars, descendants of the Kipchaks settled on the Volga in the 13th century, where they mingled with survivors of the old Bulgarians and partly with Finnish stems. They speak a pure Turkish dialect; they are middle-sized, broad-shouldered and strong, and mostly have black eyes, a straight nose and salient cheek bones They are Mohammedans; polygamy is practised only by the wealthier classes. They are excellent agriculturists and gardeners, very laborious, and have a good reputation for honesty. (2) The Bashkirs who live between the Kama, Ural and Volga are possibly of Finnish origin, but now speak a Tatar language and have become Mohammedans. (3) The Astrakhan Tatars are agriculturists and gardeners. The Kundrovsk Tatars still continue the nomadic life of their ancestors. (4) The Crimean Tatars, who occupied the Crimea in the 13th century, have preserved the name of their leader, Nogai. The mountain Tatars closely resemble

those of Caucasus, while those of the steppes—the Nogais—are decidedly of a mixed origin from Turks and Mongols.

(5) The Tatars of Caucasia, who inhabit the upper Kuban, the steppes of the lower Kuma and the Kura, and the Aras. Of these the Nogais on the Kuma show traces of an intimate mixture with Kalmucks. They are nomads, supporting themselves by cattle-breeding and fishing; few are agriculturists. The Karachais in the upper valleys about Elburz live by agriculture. (6) The mountain Tatars, divided into many tribes, are scattered throughout the provinces of Baku, Erivan, Tiflis, Kutais, Daghestan, and partly also of Batum. They are certainly of a mixed origin, and present a variety of ethnological types. All who are neither Armenians nor Russians, nor members of any distinct Caucasian tribe, are often called Tatars. Although most fervent Shi-ites, they are on very good terms with their Sunnite neighbours. Polygamy is rare and their women go to work unveiled.

The Siberian Tatars occupy three distinct regions—a strip running west to east from Tobolsk to Tomsk, the Altai and its spurs, and South Yeniseisk. They originated in the agglomerations of Turkish stems which in the region north of the Altai reached some degree of culture between the 4th and the 8th centuries, but were subdued and enslaved by the Mongols. They are difficult to classify, for they are the result of somewhat recent minglings of races and customs. (7) The Baraba Tatars take their name from one of their stems (Barama), live in Tobolsk, a few in Tomsk, by agriculture, either in separate villages or along with Russians. (8) The Cholym or Chulym Tatars on the Cholym and both the rivers Yus speak a Turkish language with many Mongol and Yakut words, and are more like Mongols than Turks. (9) The Abakan or Minusinsk Tatars occupied the steppes on the Abakan and Yus in the 17th century, after the withdrawal of the Kirghizes, and represent a mixture with Kaibals (whom Castrén considers as partly of Ostiak and partly Samoyedic origin) and Beltirs—also of Finnish origin. Their language is also mixed. They are known under the name of Sagais. (10) The Tatars of the northern slopes of the Altai are of Finnish origin. They comprise some hundreds of Kumandintses, the Lebed Tatars, the Chernevyie or Black-Forest Tatars and the Shors, descendants of the Kuznetsk or Iron-Smith Tatars. They are chiefly hunters and have maintained their Shaman religion and tribal organization into *suoks*. They live partly also on cedar-nuts and honey collected in the forests. Their dress is that of their former rulers, the Kalmucks, and their language contains many Mongol words. (11) The Altai Tatars, or "Altaians," comprise—(*a*) the Mountain Kalmucks who have nothing in common with the Kalmucks except their dress and mode of life, while they speak a Turkish dialect, and (*b*) the Teleutes, or Telenghites, a remainder of a formerly numerous and warlike nation who have migrated from the mountains to the lowlands, where they now live along with Russian peasants.

Geogr. Soc.*, xx., 1884. Various scattered articles on Tatars will be found in the *Revue orientale pour les Études Oural-Altaïques,* and in the publications of the university of Kazañ. *See* also E. H. Parker, *A Thousand Years of the Tartars,* 1895 (chiefly a summary of Chinese accounts of the early Turkish and Tatar tribes), and Skrine and Ross, *Heart of Asia* (1899).

TATA SONS, LIMITED. This is an Indian house founded by the late Jamsetji N. Tata, a Parsi merchant and industrial pioneer.

The conduct of these enterprises of national importance is vested in the hands of Messrs. Tata Sons Ltd., of Bombay, under the chairmanship of Sir D. J. Tata, and the combined capital of their undertakings is estimated at £50,000,000 providing employment for an industrial community of nearly a quarter of a million people.

Perhaps one of the most prominent of the industrial concerns founded and managed by or associated with the firm of Messrs. Tata Sons Ltd. is the Tata Iron and Steel Co. Ltd. It took 20 years to realize this project of manufacturing iron and steel in India on western lines and on an extensive scale and to evolve a workable process of smelting India's iron ore. It cost nearly £14,500,000 to raise the works from the site of a veritable wilderness into a well ordered and up-to-date city, appropriately re-named after its great founder—Jamshedpur—the first and only steel city in India. The works have a capacity of nearly 800,000 tons of pig-iron and over 600,000 tons of finished steel per annum. Pig-iron, ferro-manganese, rails, plates, and sheets, corrugated and galvanized sheets, agricultural implements, sulphate of ammonia and sulphuric acid are some of the principal manufactures, with associated companies manufacturing electric cables, wire products and tin plate.

This hydro-electric group consists of four companies—the Tata Hydro-Electric Power Supply Co. Ltd., the Andhra Valley Power Supply Co. Ltd., the Tata Power Co. Ltd., and the Kundley Power Co. Ltd., the aggregate capital of which may be put at nearly £15,000,000. The equipment is planned to generate about 321,000 E.H.P. between the four companies, with the probability of an additional increase later on, to supply motive power to the factories, the tramways and the railway lines in Bombay and surburban extensions and to provide electricity for lighting and domestic purposes.

The contribution of the Tata house to the cotton mill industry, which made Bombay a great industrial centre commenced when the first of a group of mills—the Empress Mills—was inaugurated at Nagpur in 1877, which in time revolutionized the cotton industry in India. These mills even to-day challenge comparison with the best textile mills of Lancashire. Other mill companies have since been floated and Messrs. Tata Sons Ltd., have now under their charge, besides the Empress Mills, three others—the Svadeshi Mills, the Ahmedabad Advance Mills and the Tata Mills. The four mills have over 300,000 spindles and 7,500 looms, and bleaching, dyeing and finishing equipment. A capital of nearly £7,500,000 is involved in these mills under the management of Messrs. Tata Sons Ltd.

Besides the above, the activities of the Tata house extend to many other undertakings, such as collieries, cement factories, construction and building companies, insurance and trading companies, and an oil mill as well as a large hotel. (K. P. M.)

TATE, SIR HENRY, 1st Bart. cr. 1898 (1819–1899), English merchant and founder of the National Gallery of British Art, was born at Chorley, Lancashire, in 1819. He became a prosperous sugar-broker in Liverpool, and about 1874 removed to London, where he greatly increased the operations of his firm and made "Tate's Cube Sugar" known all over the world. He gave £42,000 to the Liverpool University College, founded in 1881; and a still larger sum to the Liverpool hospitals. When he came to London, he presented four free public libraries to the parish of Lambeth. He owned one of the best private collections of modern pictures in England. This he offered to the Nation with £80,000 for a building if the government would provide the ground; and in 1892 this offer was accepted. A new gallery, controlled by the Trustees of the National Gallery, was built on the site of Millbank Prison. The gallery was opened on July 21, 1897, and a large addition to it was completed just before the donor died. Tate died at Streatham on Dec. 5, 1899.

TATE, NAHUM (1652–1715), English poet laureate and playwright, was born in Dublin in 1652. He was the son of Faithful Teate (as the name was spelt), who wrote a quaint poem on the Trinity entitled *Ter Tria.* Nahum Tate was educated at Trinity college, Dublin, graduating B.A. in 1672. He wrote one or two original plays and a long series of adaptations from Shakespeare and the Elizabethan dramatists. Tate's name is chiefly connected with these mangled versions of other men's plays and with the famous *New Version of the Psalms of David* (1696), in which he collaborated with Nicholas Brady. A supplement was licensed in 1703. Some of these hymns, notably "While Shepherds watched," and "As pants the hart," rise above the general dull level, and are said to be Tate's work.

Tate was commissioned by Dryden to write the Second Part of *Absalom and Achitophel.* The portraits of Elkanah Settle and Thomas Shadwell, however, are attributed to Dryden, who prob-

ably also put the finishing touches to the poem. Of his numerous poems the most original is *Panacea, a poem on Tea* (1700). In spite of his consistent Toryism, he succeeded Shadwell as poet laureate in 1692. He died within the precincts of the Mint, Southwark, London, where he had taken refuge from his creditors, on Aug. 12, 1715.

TATI, a district of British South Africa attached administratively to the Bechuanaland protectorate. Area about 2,500 sq.m. The railway from Cape Town to Bulawayo crosses the territory with a station at Francistown, the principal settlement. Francistown stands 3,254 ft. above the sea and is 126 m. S.W. of Bulawayo by rail. The town of Tati, on the river of that name, is 18 m. S E. of Shashi river railway station Tati owes its importance to the presence of gold, first discovered by the German traveller, Karl Mauch, in 1864. Mining began in 1868, but it was not until 1895 that work on a large scale was undertaken. The mining rights are vested in a company, called the Tati Company, Ltd. (*See* BECHUANALAND and RHODESIA)

TATIAN (2nd cent. A D), Christian apologist, missionary and heretic. Such knowledge as we have of his life is derived from (1) his own *Oratio ad Graecos* (*see* § 3); (2) Irenaeus, *Adv. Haereses,* i. 28, i.; (3) Rhodon, quoted in Eusebius's *Hist. Eccl.* v. 13, 1; (4) Clement of Alexandria, *Strom.* i. 1, 11; (5) Eusebius, *Chronicon anno* A.D. 171, (6) Epiphanius, *Panarion,* i. 3, 46. Convenient collections of these passages may be found in E Schwartz's *Tatiani Oratio ad Graecos, Texte und Untersuchungen,* iv. 1, pp. 51–55, and in A. Harnack's *Geschichte der altchristlichen Literatur,* i. pp. 485–96. From these data the following outline of his life can be reconstructed. He was a Syrian[1] (Clem. Alex. and Epiphanius) born in Mesopotamia (*Or.* 42) and educated in Greek learning, in which he became proficient (*Or.* i. and 42). He was initiated into the Mysteries, though into which is not stated (*Or.* 29), but after this became acquainted with the Old Testament, and was converted to Christianity.

Tatian then went to Rome, where he was a hearer of Justin, and together with the latter incurred the enmity of a certain philosopher Crescens. As this fact is mentioned both in Justin's *Apology* and in Tatian's *Oratio ad Graecos,* and the *Apology* can be dated with fair security about A.D. 152 (*see* JUSTIN MARTYR), the conversion of Tatian must have been before this date. After the death of Justin he became a heretic—according to Eusebius's *Chronicon* in 173. Among his pupils were Rhodon, and, perhaps Apelles (*see* Victorinus Reat. schol. 44, in *Ep. Hieronymi ad Avitum,* ep. 124) and Clement of Alexandria (*Storm.* i 1, 11). He made a missionary journey to the East and worked in Cilicia and Pisidia, using the Syrian Antioch as the centre of his efforts (Epiphan.) The heresy which Tatian either founded or adopted was that of the Encratites. Their main doctrines were the evil nature of matter, an absolute forbidding of marriage, abstinence from wine and perhaps from meat. It would also seem that Tatian believed in the existence of aeons, one of whom was the Demiurge of the world. He denied the salvation of Adam. It is also stated that in his celebration of the Mysteries (*i.e.,* the Eucharist), he used only water. (*See* Tertullian, *De Jejun,* 15; Hippolytus, *Philos.* 8, 4, 16 and 10, 18; Jerome in *Amos* ii 12 and Iren , *Adv. Haer,* i 28, iii. 23) .

Writings.—According to Eusebius (*Hist. Eccl ,* iv. 29), Tatian wrote many books; of these the names of the following have survived.—(1) Περὶ ζῴων (mentioned in *Or ,* 15); (2) Περὶ δαιμόνων (mentioned in *Or.,* 16); (3) Λόγος πρὸς τοὺς Ἕλληνας; (4) Προβλημάτων βιβλίον (Eus., v. 13, 1—a quotation from Rhodon) an attempt to deal with the contradictions to be found in the Bible; (?5) Πρὸς ἀποφηναμένους τὰ πρὸς θεοῦ (mentioned in *Or.,* 40 as a book which Tatian intended to write, but there is no evidence that he carried his plan into effect); (6) Περὶ τοῦ κατὰ τὸν Σωτῆρα καταρτισμοῦ (Clem. Alex., *Strom ,* iii. 12, 80); (7) The *Diatessaron;* (?8) a recension of the Pauline epistles Of these books only two—the *Diatessaron* and the πρὸς τοὺς Ἕλληνας —are extant.

The Λόγος πρὸς τοὺς Ἕλληνας (*Oratio ad Graecos*) (*see* edition by J. C. T. Otto, in *Corp. apol. chr. saec,* Jena, 1851) belongs to Tatian's Catholic period. He has the double purpose in view of exposing the weakness of the pagan view of the universe and of commending the Christian explanation. The omissions in the *Oratio* are even more remarkable than its statements. There is at the most not more than an allusion to Christ, who is never mentioned by name, and though there are frequent allusions to the regaining of life, which is accomplished by union with the Logos, there is no reference to the doctrines of the incarnation or of the atonement. The *Oratio* was probably written in Greece about A D. 150.

[1]Tatian describes himself as an "Assyrian," and though the terms "Assyrian" and "Syrian" are used very loosely by ancient writers, it is probable that he was born E. of the Tigris, *i.e* , not in Syria as we understand it. Epiphanius, in another passage, calls him an Assyrian

TATRA MOUNTAINS, a name usually reserved for the highest group of the central Carpathians, viz , the Vysoké Tatry, which rises abruptly as an isolated igneous group, partly in Slovakia and partly in Poland, from a high plateau of about 2,600 ft to altitudes exceeding 8,400 ft , and extends between the rivers Váh, Poprad, Dunajec and Arva. The mountains have a west-east length of about 40 m. and a width varying from 9–15 m., notable peaks being Gerlachovka (8,737 ft), the highest in the Carpathians, Lomnický (8,642 ft.) and Kriván (8,190 ft). In everything except glaciers the range bears the Alpine imprint Small spas, well-equipped with hotels, summer resorts and centres for winter sports exist, the most frequented being Smokovec (3,250 ft), Štrba Lake (4,000 ft.) and Tatranská Lomnica (2,500 ft), while electric and rack-railways lead to the most interesting districts

South of the valley of the Váh runs a lower parallel range of similar structure, the Nízské Tatry, reaching its maximum heights in the peaks of Dumbier (6,707 ft.) and Králová Hola (6,373 ft).

(W. S L.)

TATSIEN-LU, a town in the territory of Kham (Chwanben), west of China, situated over 8,000 ft above sea-level It is a great mart for Tibet, and from Tatsien-lu the two trade routes, the Ayalam and the Janglam diverge, the former making for Ladakh and the latter for Kashgar. Pop est. 20,000

TATTA or **THATO,** an ancient town of British India, in the Sind province of Bombay, 7 m. from the right bank of the main channel of the Indus and 13 m. from a station on the North-Western railway: pop. (1921) 8,470 Tatta was the capital of the Samma dynasty in Lower Sind in the 16th century, and long continued to be the centre of trade in the country, to which it sometimes gave its name in early European travels. Its former importance reflected its location at the apex of the Indus delta An English factory was established here in 1758, but soon withdrawn

TATTERSALL'S, London horse auction mart, founded in 1766 by Richard Tattersall (1724–95), who had been stud groom to the second duke of Kingston The first premises occupied were near Hyde Park Corner, in what was then the outskirts of London Two "Subscription rooms" were reserved for members of the Jockey Club, and they became the rendezvous for sporting and betting men "Tattersall's Committee" and "Tattersall's Ring" are the descendants of these subscription rooms but are not in any way connected with the horse-mart. The former is a strong, but unofficial, organization that looks after the purity of the turf from the point of view of the bookmaker and bettor alike; and the latter is the name given to the principal betting enclosure on any race-course on which meetings are held under Jockey Club or National Hunt rules. By a House of Lords decision Tattersall's Ring is not a "place" within the meaning of the Betting Act, 1853.

TATTLER, a North American wading bird (*Heteractitis incanus*), about 11 in. long, slaty grey above and white barred with grey below. It breeds on the Pacific coast north from British Columbia, wintering in the Hawaiian Islands and the Galápagos.

TATTOOING: *see* MUTILATIONS.

TAUCHNITZ, the name of a family of German printers and publishers. Karl Christoph Traugott Tauchnitz (1761–1836), born at Grossbardau near Grimma, Saxony, established a printing business in Leipzig in 1796 and a publishing house in 1798. He specialized on the publication of dictionaries, Bibles and stereotyped editions of the Greek and Roman classics. The business

was carried on by his son, Karl Christian Phillipp Tauchnitz (1798–1884), until 1865, when the business was sold to O. Holtze. He left large sums to the city of Leipzig for philanthropic purposes. Christian Bernhard, Freiherr von Tauchnitz (1816–95), the founder of the firm of Bernhard Tauchnitz, was the nephew of the first-mentioned. His printing and publishing firm was started at Leipzig in 1837. The Library of British and American Authors, so familiar to travellers on the continent of Europe, was begun in 1841. In 1929 the collection numbered over 4,800 volumes. In 1868 he began the Collection of German Authors, followed in 1886 by the Students' Tauchnitz editions.

TAULANTII, in ancient geography, an Illyrian people in the neighbourhood of Epidamnus (Thuc. i. 24). They were originally powerful and independent, under their own kings. One of these was Glaucias, who fought against Alexander the Great, and placed Pyrrhus (*q.v.*), the infant king of Epirus, whom he had refused to surrender to Cassander, upon the throne (Plutarch, *Pyrrhus,* 3). Later the Taulantii fell under the sway of the kings of Illyria.

TAULER, JOHANN (*c.* 1300–1361), German mystic, was born about the year 1300 in Strasbourg, and was educated at the Dominican convent in that city. From Strasbourg he went to the Dominican college of Cologne, and perhaps to St. James's College, Paris, ultimately returning to Strasbourg. In 1338–1339 Tauler was in Basel, then the headquarters of the "Friends of God" (*see* MYSTICISM), and was brought into intimate relations with the members of that pious mystical fellowship. He died on June 16, 1361.

Tauler's sermons were printed first at Leipzig in 1498, and reprinted with additions from Eckhart and others at Basel (1522) and at Cologne (1543). There is a modern edition by Julius Hamberger (Frankfort, 1864), and R. H. Hutton published Tauler's Sermons for Festivals under the title of *The Inner Way. See* Denifle, *Das Buch von geistlicher Armuth* (Strassburg, 1877); Carl Schmidt, *Johann Tauler von Strassburg* (Hamburg, 1841); S. Winkworth, *Tauler's Life and Sermons* (1857); R. A. Vaughan, *Hours with the Mystics,* 3rd ed., vol. i. pp. 214–307; Preger's *Gesch. der deutschen Mystik im Mittelalter,* vol. iii.; W. R. Inge, *Christian Mysticism:* R. M. Jones, *Studies in Mystical Religion* (1909).

TAUNG-GYI: *see* SHAN STATES.

TAUNTON, a municipal borough and market town of Somersetshire, England, on the river Tone, 44¾ m. S.W. of Bristol by rail, on the G.W.R. Pop. (1921) 23,223. Standing in the valley of Taunton Dean, the town is chiefly built on the south side of the river. Taunton is the county town of Somerset.

There is evidence of an early settlement near the suburb of Holway, and Taunton (Tantun, Tantone, Tauntone) was a place of considerable importance in Saxon times. King Ine erected an earthen castle here about 700, and a monastery was founded before 904. The bishops of Winchester owned the manor, and obtained the first charter for their "men of Taunton" from King Edward in 904, freeing them from all royal and county tribute. At some time before the Domesday Survey Taunton had become a borough with very considerable privileges, governed by a portreeve appointed by the bishops. Two members were returned to parliament from 1299 to 1885. The Saturday market dates from before the Conquest.

Its main streets converge upon a triangular space, where there is a market cross. The parish church of St. Mary Magdalene is a fine Perpendicular building. Remnants of Norman work are preserved in the chancel arch, and of Early English work in the north aisles and transepts. The tower is also a notable feature. Little is left of an Austin priory established in the reign of Henry I. by William Giffard, bishop of Winchester, who also built the castle, now a museum for prehistoric, Roman and medieval antiquities. At the Restoration it was dismantled and its moat filled in. Among the schools is a grammar school founded in 1522 by Richard Fox, bishop of Winchester.

TAUNTON, a city of Massachusetts, U.S.A., one of the county seats of Bristol county; 35 m. S. of Boston, at the head of ocean navigation on the Taunton river, 14 m. above Fall River. It is served by the New York, New Haven and Hartford railroad and several steamship lines. Pop. (1920) 37,137 (27% foreign-born white, largely from the Atlantic islands, Portugal, Canada and Ireland) and 39,255 in 1925 (State census). Within the corporate limits of the city (which has an area of 44·25 sq.m.) are six villages. The old "common," fringed with lofty elms, is the centre of the business section of the modern city, and about a mile from "the Weir," at the harbour. Its manufacturing industries are extensive and varied, including large cotton mills, britannia-ware factories and stove foundries. The aggregate output in 1925 was valued at $31,744,082. The city's assessed valuation for 1927 was $41,380,020. Taunton was founded in 1638, and became the frontier town of Plymouth Colony. Myles Standish was engaged on the original survey. The town was incorporated in 1639, taking the name of the English home of many of the settlers. It was a base of operations during King Philip's War. In 1686 it refused to comply with the demands of Sir Edmund Andros for a tax levy. In 1774, after the passage of the Boston Port Bill, a red flag inscribed "Liberty and Union" was raised on the Common in token of sympathy with Boston. During the Shays Rebellion the court-house was twice besieged by insurgents, who were dispersed on both occasions by one of the judges, Gen. David Cobb. Industrial development began with the establishment of ironworks in 1656. Brick-making and ship-building were important early industries, and for some time Thomas Coram, founder of the London Foundling hospital, was one of those engaged in the latter. In the adjoining town of Berkley is the famous Dighton Rock, with inscriptions long attributed to the Norsemen, but now known to be the work of Indians. Taunton was chartered as a city in 1864. It was one of the first cities in the United States to operate its own electric-lighting plant, which it acquired in 1897.

TAUNUS, a wooded mountain range of Germany in the province of Hesse-Nassau. It lies between the Rhine and the Main on the south and the Lahn on the north, and is some 55 m. long. Its southern edge stands 5 to 10 m. back from the Main, but slopes steeply to the Rhine, and from Bingen downwards forms precipitous crags, many of which are crowned with picturesque ruins. It has an average elevation of 1,500 ft., but the loftiest peaks occur in the east, where the Grosser Feldberg (2,887 ft.), Kleiner Feldberg (2,714 ft.) and Altkönig (2,618 ft.) dominate the Wetterau and the valley of the Main. Above the Rheingau (the slopes to the Rhine between Biebrich and Bingen), the altitude averages 1,500 to 1,700 ft. The geological core of the system consists of (?Archean) argillaceous schists, capped by quartzite (Devonian) and broken through in places by basalt. On the northern side, which sinks on the whole gently towards the Lahn, the higher greywacke formation (Devonian) attains a considerable development. The hills are generally well wooded, with firs and beeches. The lower slopes are, where possible, planted with vineyards, orchards and chestnut and almond groves. The vineyards of the Rheingau are specially famous, and yield many famous brands of wine. The Taunus is also famous for its mineral springs and health resorts.

There are ruins of the castle of Kuno (above Falkenstein); of a fortress at Königstein; a Cistercian abbey at Eberbach; and two concentric lines of pre-Roman fortifications at Altkönig. The chief historical monument, however, is the Saalburg, a Roman fort serving as a centre of communications along the *limes* or fortified frontier-line drawn from Rhine to Main by Domitian (*see* LIMES GERMANICUS).

At Niederwald (*q.v.*) is the gigantic "Germania" statue in commemoration of the 1870 War. The steep crags of the western end of the Taunus, where they abut upon the Rhine, are rich in the romantic associations of the great river. Here are the rock of the siren Lorelei; the old castles of Stahleck and Pfalz; and the quaint mediaeval towns of Kaub and St. Goarshausen.

TAUPO, a township of East Taupo county, New Zealand, in the south-west of the Hot Spring district of North Island. It attracts many visitors both as a health resort and on account of the magnificent scenery and remarkable volcanic phenomena of the surrounding district. It lies on the north-east shore of lake Taupo, the largest lake in the island, having an extreme length of 26 m. and a shore-line, not counting minor indentations, of about 100 m., and lying 1,200 ft. above sea-level. The river Waikato, which reaches the west coast not far from Manukau

Harbour near Auckland, here leaves the lake. The district abounds in geysers, springs, mud volcanoes and other phenomena.

TAURI, the earliest known inhabitants of the mountainous south coast of the Crimea (Herodotus iv. 103). Nothing is certain as to their affinities. They probably represent an old population perhaps connected with some Caucasus stock. They are not likely to be Celts. They were famous in the ancient world for their maiden goddess, identified by the Greeks with Artemis Tauropolos or Iphigeneia (*q.v.*), whom the goddess was said to have brought to her shrine at the moment when she was to have been sacrificed at Aulis. Orestes sought his sister, and almost fell a victim to the Tauric custom of sacrificing to the maiden shipwrecked strangers, a real custom which was the ground of the whole myth. His adventures were the subject of plays by Euripides and Goethe. Towards the end of the 2nd century B.C. we find the Tauri dependent allies of the Scythian king Scilurus, who from their harbour of Symbolon Portus or Palacium (Balaclava) harassed Chersonese (*q v*) Their later history is unknown. (E. H. M.)

TAURINI (tou-rē'nē), an ancient Ligurian people, although the name may be of Celtic origin, who occupied the upper valley of the Padus (Po). In 218 B C they were attacked by Hannibal, with whose friends the Insubres they had a long-standing feud. They later became subject to the Romans, and the colony of Augusta Taurinorum (Torino, Turin) was founded in their territory (probably by Augustus after the battle of Actium). Both Livy (v 34) and Strabo (iv p 209) speak of the country of the Taurini as including one of the passes of the Alps, probably the Mont Genèvre or Col d'Argentière

TAUROBOLIUM, properly the shooting of a bull, hence a rite of baptism by bull's blood, usually in connexion with the worship of Cybele (q v), though not limited to it. Of oriental origin, its first known performance in Italy was in A D. 134. Prudentius describes it in *Peristephanon* (x , 1066 et seq): the person undergoing the ceremony, clad in a toga worn *cinctu Gabino,* with golden crown and fillets on his head, takes his place in a trench covered by a grating, on which a bull is slain.

The taurobolium was often performed as a measure for the welfare of the emperor, empire, or community, its date frequently being March 24, the *Dies Sanguinis* of the annual festival of the Great Mother and Attis (qq v). But its usual motive was the purification or regeneration of an individual, who was occasionally spoken of as *renatus in aeternum,* reborn for eternity, in consequence of the ceremony (*Corp Insc Lat.* vi. 510–512); more commonly the effect was considered to endure for 20 years

TAURUS ("the Bull"), in astronomy, the second sign of the zodiac denoted by the symbol ♉. It is a constellation of very great antiquity, the Pleiades (*q v*), and Hyades, two of its constituent star clusters, being possibly referred to in the Old Testament; while Aldebaran, its brightest star, is mentioned by Hesiod and Homer. The Greeks fabled this constellation to be the bull which bore Europa across the seas to Crete, and was afterwards raised to the heavens by Jupiter Aldebaran is the principal object in the Hyades, named after the seven daughters of Atlas and Aethra—Ambrosia, Coronis, Eudora, Pasithoë, Plexaris, Pytho and Tycho—fabled by the Greeks to have been transformed into stars by Jupiter for bewailing the death of their brother Hyas. Many of the Hyades (but not including Aldebaran) form an associated group of stars with a common motion This group was investigated by L Boss and has furnished much important astronomical information (*see* STAR). The constellation contains the "crab nebula," so named from its claw-like protuberances

TAUSEN, HANS (1494–1561), the protagonist of the Danish Reformation, was born at Birkende in Funen in 1494. The quick-witted peasant lad ran away from the plough at an early age, finally settling down as a friar in the Johannite cloister of Antvorskov near Slagelse After teaching for a time at Rostock and Copenhagen, he was again sent abroad by his prior, visiting the newly founded University of Leyden and making the acquaintance of the Dutch humanists. He was already a good linguist, understanding both Latin and Hebrew. Later he translated the books of Moses from the original. In May 1523 Tausen went to Wittenberg, where he studied for a year and a half, when he was recalled to Antvorskov. In consequence of his adherence to Lutheran doctrines he was first imprisoned in the dungeons of Antvorskov and thence transferred, in 1525, to the Grey Friars' cloister at Viborg in Jutland, where he preached from his prison to the people assembled outside, till his prior, whom he won over to his views, lent him the pulpit of the priory church.

Several young men in Viborg had studied at Wittenberg, and the burghers had already expelled their youthful bishop Jörgen Friis. Tausen no longer felt safe among the Franciscans; he discarded his monastic habit, and placed himself under the protection of the burgesses of Viborg. At first he preached in the parish church of St. John, then in the market-place from the church tower. When the Franciscans refused to allow him to preach in their large church, the mob broke in by force. A compromise was at last arranged, whereby the friars were to preach in the forenoon and Tausen in the afternoon. The bishop sent armed men to the church to arrest Tausen, but the burghers drove them back. In Oct. 1526 King Frederick I., made Hans Tausen one of his chaplains, and charged him to continue "to preach the holy Gospel" to the citizens of Viborg, who were to be responsible for his safety. Tausen found a fellow-worker in Jorgen Viberg, better known as Sadolin, whose sister, Dorothea, he married. He was the first Danish priest to marry He was also the first to use Danish instead of Latin in the church services.

On the death of King Frederick, Tausen, at the instance of Ronne, was, at the *Herredag* of 1533, convicted of blasphemy and condemned to expulsion from the diocese of Sjaelland, whereupon the mob rose in arms against the bishop, who would have been murdered but for Tausen's intervention Ronne then permitted Tausen to preach in all his churches on condition that he moderate his tone. On the final triumph of the Reformation Tausen was appointed bishop of Ribe (1542), an office which he held for 20 years

See Suhr, *Tausens Levnet* (Ribe, 1836); *Danmarks Riges Historie,* vol. ii. (Copenhagen, 1897–1905).

TAUSSIG, FRANK WILLIAM (1859–), American economist, was born at St. Louis, Mo , on Dec. 28, 1859 He was educated at Harvard university (A B., 1879; Ph D., 1883), where he started teaching in 1882, becoming professor of political economy ten years later. He made a particular study of finance and was during 1917–19 chairman of the U S. tariff commission. In March 1919 he was called to Paris to advise in the adjustment of commercial treaties. He was in 1904–05 president of the American Economic Association and for many years edited the *Quarterly Journal of Economics.* His principal books are: *Wages and Capital* (1896); *The Tariff History of the United States* (rev ed , 1923); *Principles of Economics* (1911); *Some Aspects of the Tariff Question* (1915); *Inventors and Money Makers* (1915); and *International Trade* (1927).

TAUT, BRUNO (1880–), German architect, was born in 1880 at Königsberg After practical experience as a mason, he studied architecture and was for five years a colleague of Theodor Fischer He was for some time municipal architect in Magdeburg, but subsequently removed to Berlin to work principally in collaboration with Max Taut (b. 1884) and Franz Hoffman (b 1884). He traces the beginning of the industrialization of building back to Karl Friedrich Schinkel (1781–1841) through the Crystal Palace and the Eiffel Tower to Otto Wagner (1841–1918), although other authorities have pointed to Monier as the first to use ferro-concrete where previous engineers had used simple iron and glass. His works include a glass and iron building at the building exhibition, Leipzig (1913); a glass house at the Werkbund exhibition, Cologne (1914); the Stadt und Land Hall, Magdeburg (1922), the outside of which is beautifully designed in flat curves, while the hall itself, the segment of a circle, is ornamented by the constructional features of the roof; a housing-block at Schillerpark (1925), the effect of which is made by the emphasized rectangles of the façade; and the "Gehag" garden

city (Berlin-Zehlendorf) in conjunction with Häring and Salvisberg, which admirably illustrates his requirements of domestic architecture. His publications include: *Die Stadtkrone* (Jena, 1919); *Alpine Architektur* (Münich, 1920); *Der Weltbaumeister* (Münich, 1920); *Die Auflösung der Städte* (Münich, 1920); *Die Neue Wohung* (Leipzig, 1924); *Bauen* (Leipzig, 1927); *Ein Wohnhaus* (Stuttgart, 1928).

TAUTOMERISM: *see* ISOMERISM.

TAVERNER, JOHN (*c.* 1495–1545), English composer, was born in Lincolnshire, possibly at Tattershall, about 1495, and, according to some accounts, became organist of Boston church. The bishop of Lincoln recommended him to Wolsey for an appointment at Cardinal college, Oxford, where he was made master of the children, and also acted as organist at St. Frideswide's, the chapel of the college. During this period he wrote his church music. He was then convicted of heresy and thrown into an underground prison with his companions, escaping with his life only through the cardinal's indulgence to him as a musician. It has been assumed that he was identical with the John Taverner who assisted at the burning of the Rood in 1539, and other fanatical doings at Boston. All that is definitely known, however, is that he was still at Cardinal college, writing songs for Wynkyn de Worde's song-book ("My Harte my Minde," "Love wyll I," for three voices, and "The Bella" for four), in the year 1530, and that he died and was buried at Boston in 1545. A two-part song, "In Women no Season is Rest or Patience," is in the British Museum, but, apart from this and the Wynkyn de Worde specimens, only his church music has been preserved. Of this there is a complete collection, with biographical notes, in the Carnegie edition of *Tudor Church Music*, i., iii. It includes eight masses; 28 motets (some incomplete); three magnificats and a Te Deum; a Kyrie known as the "Leroy," and shorter pieces.

See the article "Taverner," by Rev. E. H. Fellowes, in Grove's *Dictionary*, 3rd ed., on which the present article is based.

TAVERNIER, JEAN BAPTISTE (1605–1689), French traveller and pioneer of trade with India, was born in 1605 at Paris, where his father Gabriel and uncle Melchior, Protestants from Antwerp, pursued the profession of geographers and engravers. He had already travelled much in Europe, and was well acquainted with the principal European courts, when he started from Regensburg with two French fathers, M. de Chapes and M. de St. Liebau, for the Levant. In their company he reached Constantinople early in 1631, where he spent eleven months, and then proceeded by Tokat, Erzerum and Erivan to Persia. His farthest point in this first journey was Isfahan; he returned by Baghdad, Aleppo, Alexandretta, Malta and Italy, and was again in Paris in 1633. In September 1638 he began a second journey (1638–43) by Aleppo to Persia, and thence to India as far as Agra and Golconda. His visit to the court of the Great Mogul and to the diamond mines was connected with the plans realized more fully in his later voyages, in which Tavernier traded in costly jewels and other precious wares, among the greatest princes of the East. The second journey was followed by four others. In his third (1643–49) he went as far as Java and returned by the Cape; in his last three journeys (1651–55, 1657–62, 1664–68) he did not proceed beyond India. In 1669 he received letters of nobility and in 1670 purchased the barony of Aubonne, near Geneva.

Tavernier's narratives of his travels are: *Nouvelle Relation de l'Intérieur du Sérail du Grand Seigneur* (4to, Paris, 1675), based on two visits to Constantinople in his first and sixth journeys; *Le Six Voyages de J. B. Tavernier* (2 vols., 4to, Paris, 1676) and *Recueil de Plusieurs Relations* (4to, Paris, 1679).

The closing years of Tavernier's life are obscure. He left Paris for Switzerland in 1687, in 1689 he passed through Copenhagen on his way to Persia through Muscovy, and in that year he died at Moscow.

See Charles Joret, *Jean Baptiste Tavernier d'après des Documents Nouveaux* (1886, bibliography), and an English translation of his account of his travels in India, by V. Ball (1889).

TAVISTOCK, a market town in the Tavistock parliamentary division of Devon, England, in the valley of the Tavy, on the western border of Dartmoor; 16½ m. N. of Plymouth, on branch lines of the G. W. and S. railways. Pop. of urban district (1921) 4,316. There are some remains (including a portion in the square, now used as a public library established in 1799) of the magnificent abbey of St. Mary and St. Rumon, founded in 961 by Orgar, earl of Devon. After destruction by the Danes in 997 it was restored, and among its famous abbots were Lyfing, friend of Canute, and Aldred, who crowned Harold II. and William, and died archbishop of York. The abbey church was rebuilt in 1285, and the greater part of the abbey in 1457–58. The church of St. Eustachius dates from 1318, and possesses a lofty tower supported on four open arches. Kelly college, near the town, was founded by Admiral Benedictus Marwood Kelly, and opened in 1877 for the education of his descendants and the orphan sons of naval officers. Mines of copper, manganese, lead, silver and tin are in the neighbourhood, and the town possesses a considerable trade in cattle and corn, and industries in brewing, wool-combing and iron-founding. The mining industry has declined, but there is a trade in arsenic.

The early history of Tavistock centres round the abbey of St. Rumon. Both town and abbey were sacked by the Danes in 997, but were shortly afterwards rebuilt, and the latter at the time of the Conquest ranked as the wealthiest house in Devon, including the hundred and manor of Tavistock among its possessions. It returned two members to parliament as a borough from 1295 until deprived of one member by the act of 1867, and finally disfranchised by that of 1885.

See *Victoria County History, Devonshire;* A. J. Kempe, *Notices of Tavistock and its Abbey* (1830); R. N. Worth, *Calendar of Tavistock Parish Records* (Plymouth, 1887).

TAVOY, a town and district in the Tenasserim division of Burma. The town is on the left bank of the river of the same name, 30 m. from the sea. Pop. (1921) 27,480. It carries on a considerable coasting trade with other ports of Burma, and with the Straits Settlements whither is sent the bulk of the tin ore for which the district is important, as well as much of the rubber. The chief industry is silk-weaving, but there are also rice and timber mills.

The district has an area of 5,308 sq.m. It lies between Siam and the Andaman sea of the Bay of Bengal, enclosed by mountains on three sides, viz., the main chain of the Bilauktaung on the east, rising in places to 5,000 ft., which, with its densely wooded spurs, forms an almost impassable barrier between British and Siamese territory; the Nwahlabo in the centre, which takes its name from its loftiest peak (5,000 ft.); and a third range, under the name of Thinmaw, between the Nwahlabo and the sea-coast. The Tavoy is navigable for vessels of any burden. It is interspersed with many islands, and with its numerous smaller tributaries affords easy and rapid communication. The climate is on the whole pleasant. The annual rainfall averages over 200 inches. Pop. (1921) 156,786, showing an increase of 21,493 in the decade. The staple crop is rice. Forests cover an area of nearly 5,000 sq.m., of which considerable areas are "reserved." The leading industries of the district are now rubber planting and tin mining, both of which are of recent development.

Tavoy, with the rest of Tenasserim, was handed over to the British at the end of the first Burmese war in 1824.

TAXACEAE: *see* GYMNOSPERMS.

TAXATION, that part of the revenue of a state which is obtained by compulsory dues and charges upon its subjects, as distinct from revenue from property of its own.

Where the charge by the State or public authority bears a direct relation to the service rendered direct to the payer, and is on a contractual basis, as though between individuals, the amounts paid are usually classified as fees and charges, rather than taxes.

Definitions and Classifications.—Taxes are classified for various purposes in different ways, *e.g.*, direct and indirect; beneficial and onerous; local and national; proportional, regressive and progressive; taxes *in rem* and *in persona*. It is necessary to consider some of these distinctions if the general literature of the subject is to be understood.

The distinction between direct and indirect taxation is mainly

an administrative one It is a classification for convenience sake, adopted upon a rough observation of conspicuous, or apparently conspicuous, differences in the mode of levying taxes, and nothing more. The division, nevertheless, cannot be passed over without mention, as it is not only a common one in economic writing, but it figures largely in budget statements, financial accounts and finance ministers' speeches—especially in the United Kingdom and France In the United Kingdom the distinction has been made familiar by free-trade discussions. Direct taxes are those finally borne by the actual payer, but where the legislation does not intend the tax to fall upon the payer, and expects him to pass it on, in price, or otherwise by altering the terms of a bargain, it is indirect. Thus income tax is classed as direct, although often paid by a tenant on behalf of his landlord and specifically deducted from rent, but beer duty paid by the brewer, and passed on in price to the publican, and by him to the consumer, is indirect; a motor licence duty paid by a private owner is direct, though it appears to be indirect where it is charged upon a vehicle for public hire and is an expense of carrying on a business which is expected to be recovered from fares. But petrol tax is obviously indirect. The distinction has little actual economic basis, because the effect of the tax in retarding production or consumption may be such as to throw the burden elsewhere, and the customer may, in consequence of the higher price, drink less beer, and the brewer, through selling less, make lower profits.

The distinction between direct and indirect taxes has not always been drawn upon present lines. By direct taxes the physiocrats meant any taxes levied immediately upon the "product net" out of which fund alone could taxes be paid. A levy of taxes anywhere else was indirect because the burden would be shifted from one to another until it rested there. This distinction fell into disuse as their theory of the location of wealth was discarded. Later writers took into account the difficult question of economic shifting. The French have not been in the habit of classifying customs duties as indirect. In the United States at the time of the Civil War the courts declared the income tax not to be "direct" in the sense intended by the constitution, but this decision was overborne in 1895

"Local" and "national" refer not so much to the administrative body which formally imposes and collects a tax, as the body which is responsible for the decision to impose it. Income tax is collected locally, but it is a national tax, alike in weight over the whole area. Poor rates are local because they vary from district to district, but though the jurisdiction over them is local, it is regulated under general acts. But abroad, local revenues are sometimes raised by being "geared on" to a national tax, the differing local requirements are represented by varying percentage supplements to the national income tax, and collected with it In other cases, such as Germany, the national tax is for the most part passed on in percentage grants to States and communes. Customs duties are national, but the octroi is local

Taxation is "proportional" if the payment any person is required to make varies directly with the amount of income or wealth the payer possesses, "regressive" if the burden becomes a less percentage of income or wealth as the latter increases, and "progressive" if it becomes a greater percentage. Thus local rates are said to be regressive, because the average amount paid by a householder with £5,000 a year is a less percentage of his income than that paid by one with £500 a year. But the income tax and estate duties are now almost universally progressive.

Taxes *in rem* are laid or assessed upon a thing or physical object, regardless of the circumstances of its owner, *e.g.*, a motor licence, or a house tax; while taxes *in persona* pay due regard to the financial status and domestic circumstances of the payer, *e g.*, income tax and death duties.

Fundamental Principles.—Adam Smith's famous canons or maxims were:—

1. The subjects of every State ought to contribute towards the support of the Government as nearly as possible in proportion to their respective abilities, *i e.*, in proportion to the revenue which they respectively enjoy under the protection of the State.

2. The tax which each individual is bound to pay ought to be certain and not arbitrary. The time of payment, the manner of payment; the quantity to be paid, ought all to be clear and plain to the contributor and to every other person.

3. Every tax ought to be so levied at the time or in the manner in which it is most likely to be convenient for the contributor to pay it.

4. Every tax ought to be so contrived as both to take out and keep out of the pockets of the people as little as possible over and above what it brings into the public treasury of the State.

Ability to Pay.—The principle of "ability to pay" is not nearly so simple in application as it appears at first sight. Formerly it was thought to lead logically to proportional taxation (*see* above), but now it is generally agreed to require progression. It is now considered to be best tested by the total wealth of an individual, or else by his income over a certain unit of time The unit varies with different classes of people, *e.g*, weekly wage earners against business owners With high rates of taxation, income may have to be carefully dissected to take out elements that are not pure income (for example, the wasting asset in an income from a diamond mine, or the capital element in an annuity). The nature of the income, whether it is precarious, or, on the other hand, independent of the work and health of the recipient, is more generally regarded, and a difference in the burden is made, while there is also a growing tendency to consider whether the income is burdened with inevitable family claims. These different elements have been recognized only in recent years, and taxation, formerly mostly "objective" and equal for every pound of income to every man, has become highly "subjective" or personal to individual loss. A few years ago a bachelor in Great Britain with £1,000 per annum from investment paid the same tax as a man with a salary of £1,000 and a wife and family of children and a number of dependent relatives

Adam Smith's principles have thus been elaborated in British practice, especially as regards the first and the refinements of the principle of ability; for the other canons are really only common-sense administrative rules, and do little as a guide to the proper amounts of taxation to be levied between different classes A recent addition to the category of "ability to pay" is the special ability or "windfall" principle, which postulates that a special addition to the regular flow of wealth or income, not counted upon by the individual in regulating his expenditure and mode of life, has a greater capacity to bear taxes without hurting him than a similar amount which forms a regular part of his receipts Thus a higher rate of tax upon a legacy received from a distant relation than on a similar amount from a near relation (from whom one had "legitimate" expectations) has been justified on this principle, and so also have various increment taxes The excess profits duty in war time was based mainly on the principle that in a time of general hardship anyone who found himself enjoying larger profits than in peace time was specially lucky and could well make a special contribution to the Exchequer

Successful personal taxation is a great test of advanced administrative methods. It is always a failure where Government is not strong and uniform in its nation-wide application In modern times so much wealth is only loosely attached to individuals—the profits of companies which are not distributed as dividends. or the wealth of corporate bodies—and taxation of these non-personal elements has to be reached by the same system (*See* INCOME TAX.)

Ad Valorem Duties.—Adam Smith's second maxim (of uncertainty) is perhaps most nearly violated in modern times by the practice of imposing *ad valorem* and not fixed or specific duties on commodities. Specific duties applied to classes of goods of widely varying quality are obviously a higher proportionate tax upon the goods of poor quality and low price than upon the best quality. A duty of 1d. per cigar would be a very heavy tax upon a cheap cigar, and a very light one upon a Corona. This can be represented as a regressive tax upon the poor and favouring the rich, and also as very disturbing to production. If it is to raise a substantial duty over the whole class, it may even be so high as to lead to substitution in the lower grades of quality, a process which may easily raise the costs of production of the

higher grades. The *ad valorem* duty is the natural escape, but the successful administration of a highly complex tariff requires a better and more skilled and honest staff of valuers or assessors than many countries are prepared to admit or afford. Although, therefore, an *ad valorem* tax is theoretically a certain tax, and the same levy must always be made upon this same quality, defects of administration may make it arbitrary and uncertain.

Adam Smith's third maxim is an administrative rule. In practice to-day taxes are levied at that point in the productive process, or the course of distribution, which is most convenient. Where "bonded" warehouses are available, duty payments may be postponed until there is actual withdrawal for use. It is generally considered that taxes on raw materials infringe the fourth maxim. If taxes are imposed at the first process, capital is locked up in the tax, and the payer has to secure interest upon it, and the user must get interest upon interest until the price of the final article has rolled up compound interest on the tax. Taxes on raw materials are almost universally condemned, but the reasoning behind these objections is not, from an economic point of view, particularly sound. A more important infringement of the fourth rule is the indivisibility of a tax. "Where a charge upon a commodity is not of such a figure as to be easily divisible among the ordinary units of retail consumption, so that it can be passed on to a consumer of the articles in the form of an increased price, it may remain fixed upon those who first pay it, at least for a time. This is supposed to have actually happened with the increase of the beer duty in the British budget of 1894 by 6d. per barrel—a sum which would not when divided by the pints in a barrel amount to the smallest coin." It is, therefore, the object of the financial authority to impose a tax on the commodity which may find a proportional equivalent in the price of a minimum quantity usually demanded—thus a penny on a gallon of beer would have no workable equivalent on the half pint.

Relations Between Direct and Indirect Taxation in Great Britain.—Much discussion has centred on the relations between direct and indirect taxation, and for many years it was thought, for no very clear reason, that the Government should "hold the balance even" between their respective yields. In 1840 in the United Kingdom indirect taxation was 73%, in 1870, 61%, in 1880, 60%, in 1895, 62%, and in 1906, 50%—for many years it hovered round this figure. To-day there is much less regard paid to the proportions, since direct taxes have developed to a marked extent, and there is a recent tendency to look at them as part of a common system, and all taxes taken together are reduced to a percentage of total income at each grade of income to determine the effect. Indirect taxes are justified in this view for their administrative convenience in reaching the incomes of the poorer classes who are only with difficulty brought within direct taxes, such as income tax, and death duties, and who otherwise would have political power and control over expenditure without any share in the responsibility.

The causes of the trend towards more direct taxation may be summarized in a three-fold classification:—

(1) *Natural Administrative Development.*—It is most natural for countries in their early stages of development to rely almost entirely upon indirect taxation, and in proportion as they become more highly differentiated in function or densely populated, and industrialized so as to be more completely of the type of western civilization—in that proportion is it found more administratively possible to resort to direct taxation. A country that is sparsely peopled has ill-developed administrative machinery. In agriculture it is always difficult to assess incomes, and it often takes many years after the adoption of an income tax to attain a high degree of administrative efficiency. A country in an early stage of development has to rely very largely upon a scattered and not too skilled administration, perhaps with no tradition of industry and probity. Such a country has one or two main outlets for its produce, and means of ingress for imports, confined to one or two chief ports, and by concentrating administration at these places, the gateways, as it were, of the country, it is possible to levy toll on things going in and out. Consumption taxes or taxes upon produce are the rule. These taxes are most easily checked at the points of ingress and egress.

(2) *Social and Political Reasons.*—Democracy has a growing power politically to put the major burden upon a minority. A landowning majority tends to put the weight upon manufacture and wages. Seligman says the indirect taxes of the 19th century were the outgrowth of the effort on the part of the commercial classes to escape the burdens which the landowners were desirous of placing upon them. Socialistic theories desire to equalize incomes, and heavy taxation of the rich is one important method. But this cannot be achieved by ordinary indirect taxes.

(3) *Economic Causes.*—The principle of ability to pay has led in recent times to progression (*see* below) through the economic principles of diminishing utility and equal sacrifice. This can only be attained by direct taxes.

According to calculations by Sir Herbert Samuel, before the Royal Statistical Society in 1903, the income of £150 a year bore ·1% of direct and 4·8% of indirect taxes. In 1918 this was ·1% and 10·9% respectively. For the £500 income the 1903 figure was 5·6% direct, 3·1% indirect, 8·8% total, and the 1918 figures 12% direct, 6·1% indirect, total 18·1%. The 1903 income of £5,000 bore 8·7% direct, 0·8% indirect, total 9·6%, but in 1918 the £5,000 income bore 42·2% direct, 1·3% indirect, 43·5% total. The £50,000 income bore 10·2% direct, ·08% indirect, total 10·2% in 1903, and 63·7% direct, ·1% indirect, total 63·9% in 1918.

It is true to say that the smaller incomes during the last 100 years have been so systematically relieved from taxation that, if a workman chose not to drink alcohol or to smoke, his taxation was almost negligible.

The report of the Colwyn Committee on Taxation deals exhaustively with the comparative burdens per head at different dates. The following is a selection of the conclusions (Report pp. 94–5) which differs in small details from the foregoing:—

Total Taxation: Percentage of Income

Income	Income wholly earned			Income half earned half investment		
	Direct	Indirect	Total	Direct	Indirect	Total
	%	%	%	%	%	%
1913–14						
100	..	5·4	5·4	1·2	5·4	6·6
150	0·2	4·2	4·4	1·4	4·2	5·6
500	2·6	1·8	4·4	5·3	1·8	7·1
5,000	6·0	0·7	6·7	8·9	0·7	9·6
50,000	8·3	0·1	8·4	13·5	0·1	13·6
1918–19						
100	..	9·9	9·9	1·2	9·9	11·1
150	0·2	8·8	9·0	1·4	8·8	10·2
500	7·0	3·2	10·2	10·3	3·2	13·5
5,000	35·9	0·7	36·6	38·5	0·7	39·2
50.000	50·5	0·1	50·6	58·1	0·1	58·2

The Progressive Principle of Taxation.—No change of opinion has been so great or so complete in the past fifty years as that upon progression. Adam Smith was, except in one or two passages, an exponent of proportion. Probably he went as far as was necessary in an age when regression was more commonly held as a defensible system. The nineteenth-century view is M'Culloch's oft-quoted remark, "When you abandon the plain principle (of proportion) you are at sea without rudder and compass, and there is no amount of injustice you may not commit."

In 1922 Sir Robert Giffen wrote, "As to progressive taxation based on the assumption that equality requires a larger proportionate charge upon a big income than on one of a smaller amount, the practical application of the principle, if true, would be impossible. A great deal more would need to be known than is now known as to the effect of taxes on different classes, and the aggregate amount of different incomes, before such a tax could

be undertaken If there is a greater proportionate charge already on the larger incomes, nothing more need be done, and we cannot know that there is not

The doctrine of the minimum of subsistence was advanced by Bentham in the form of leaving untouched a certain minimum of income sufficient to provide the necessaries of existence.

There is no magic about the *minimum of subsistence.* It is not an absolute "I well remember, when I was serving on the Dawes Committee on German Reparations, and we were considering the question of comparative national ability to bear burdens, with the necessary comparisons of total national incomes, the various nations agreed that the *minimum of subsistence* for each population should first be deducted, as it was only the balance of income that was capable of bearing a special burden. This minimum per head was, therefore, explored by the various representatives The Americans were amazed at the figure suggested by the French and the Italians, and surprised even at the British; it seemed to them incredible The Italians could not admit the British suggestion, and as for the American idea—when applied to Italy it blotted out the whole national income." (Sir Josiah Stamp, *The Christian Ethic as an Economic Factor.*)

The philosophical or mathematical basis of progression as a just principle has been debated since Montesquieu, and writing in 1894 Seligman was able to point to the growing Continental practice, and also the support of marginal theory in economics "as indicative of a great change." The principle is based on the diminishing satisfaction given by utility of money or wealth as a whole to its possessor, with every increase in it, satisfying less and less urgent wants, so that to take a shilling from the 10,000th £ is not so hurtful as to take a shilling from the 100th £. Taxation in Germany was frankly progressive from 1891. In Great Britain a mild element (degression) existed in the Income Tax, and some progression in death duties, from 1894, but the first instalment of real progression came in 1909 with the super tax. In France the principle was not admitted until much later

The Incidence of Taxation.—Some of the most important issues in regard to incidence and ultimate effects are considered in the article INCOME TAX, ECONOMIC ASPECTS OF But one of the fundamental principles in connection with all taxation of a flow of particular kinds of wealth (*e g.*, taxes on mining royalties, on dividends from diamond mining, or on ground rents) is that of amortization or capitalization It rests upon two economic principles, first that a tax on results (profits) or surplus (economic rent) does not enter into price and become recouped in sales, but stays as a deduction from the particular profits taxed, second, that all such "flows" have a capital value in the market, and the market (*caeteris paribus*) is indifferent to gross yields and looks at net yields only. Thus A and B have each £100 coming from sources X and Y, and its capital value in the market is £1,500 in each case. But a 10% tax is put on X and A receives £90 only—he can only get £1,350 in the competitive market, and at once bears the capitalized (or amortized) burden of future taxation. Every purchaser takes care to buy himself "free" of the burden and to get the same rate of yield as he would from untaxed sources It is not necessary to wait for the actual imposition of the special tax—its preparation has the same effect, and even a hint of imposition begins to influence market price Of course a general income tax leaves no untaxed alternatives open to the investor and there is, therefore, no amortization

An important "negative" case is the special exemption from a general tax, *e g*, a "tax exempt security." Here the capitalized value of the tax escaped is a present to the owner at the time of the exemption, and every new holder has to give *pro tanto* more If the tax exemption is a condition of a government offer, obviously the government gets a subscription on more favourable terms in lieu of the tax they prefer. The problem of tax exempt securities is peculiarly an American one.

The principle may apply to other forms of differential taxation, *e.g.,* land values, which are not upon immediate income, but fall on future prospects. Where taxes are levied on commodities, the broad principle of an alternative untaxed supply is important. A customs duty on imports balanced by an excise on home production, throws the whole tax (B) as an addition to cost price (A) and the final effect depends upon "elasticity of demand"—if the public will not buy the old quantities at the higher price (A+B) the effect may be to reduce sales which will pass off at a rather lower level C, intermediate between A and (A+B). But, where there is no duty on the home product, the general or broad result is that the foreign exporter needs to add the tax B to his price, the home producer can secure something approximating to A+B, and his trade expands at the expense of the foreigner. This result, again, is materially qualified by elasticity of demand, internal competition, and the degree to which the foreign exporter was making large differential profits which can be cut into before he will relinquish the market. The principle of substitution is operative to a marked extent in controlling incidence. A high tax on tea may encourage the substitution of other beverages. The incidence of death duties is indeterminate—it is described by the Colwyn Committee as follows:

> On practical grounds, we think it is impossible to say that the incidence of the estate duty is uniform.
>
> If a testator has consciously stinted his expenditure and saved more year by year than he would otherwise have done, regarding the difference solely as a piling up of the tax against the day of his death, it is hard to deny that the incidence is upon him during his life.
>
> On the other hand, the feelings and action of the testator have not been influenced in any direction by the prospect of the duty, the successor is the only person who suffers and the only person to whom the incidence can well be assigned . . . When one compares the income tax with the estate duty, regarding the latter as a kind of postponed income tax, one sees clearly the solidarity of the interests of predecessor and successor. The income tax, in a concealed way, hits the taxpayer's son as well as the taxpayer himself, and may hit him just as severely But the damage is separated by a time-gap In the case of the estate duty the time-gap is bridged, and the damage is at once apparent. On the whole, we think we have good support for giving primary but not exclusive place to the notion that the incidence of the duty is on the predecessor.

The incidence of local rates on building rentals was highly debated for many years and is not finally determinable At one time, it was said that all such taxation was thrown off upon ground rents, which could, and would, be *pro tanto* higher if local rates did not exist But the reasoning upon which this was based would have applied almost equally to a reduction in the price of a "hair cut." It has to be realized that a large part of local rating is payment for value received (by the tenant) and also that local rating acts as a very rough (unshiftable) income tax

Ulterior Objects of Taxation.—It will be seen that while taxation may be in the first instance to raise revenue, it has inevitably certain "effects" in so doing. The economic community cannot be exactly the same as it would have been without the taxation. This leads to endeavours to secure "effects" by the machinery of taxation, the resultant revenue (if any) being a secondary consideration Taxation becomes an "engine of social or national policy." At any rate, it actually modifies the primary task of raising a given amount of revenue into a task of achieving that main object with a combination of desired ulterior objects. These objects may be grouped under three classes, (1) the discouragement of the use or consumption of things having disadvantageous personal or social effects, (2) the encouragement of particular trades, and (3) the equalization of wealth, and remedying of social inequality. Under the first, the temperance reformer sees virtue in making the price of alcoholic liquors so high that a given expenditure can do little personal harm; others would consider diminution of smoking a satisfactory result of tobacco duties, a tax on cats is desired to keep down their numbers, and not actually for revenue. In the second class, of course protective duties are avowedly designed to promote home production in the particular trades affected—whether there is a net national advantage after allowing for trades which use the product, for depression in exporting trades which would pay for the imports, for comparative efficiency, etc., in the trades themselves, is, of course, the complicated issue known as the "fiscal question."

Under the third head, progressive taxation of incomes and death duties is not pursued merely because it is the easiest or fairest way to raise a necessary burden or discharge a disagreeable duty—it takes on the character of a deliberate equalization of

wealth, as a goal to be aimed at, with an almost retributive character. The limits to which this can be carried without reducing the size of the national dividend, are increasingly important. (*See* CAPITAL LEVY and INCOME TAX.)

The Main Problems of Post-war Taxation.—The man in the street would declare that the main problem is to reduce it. But given the necessity or inevitability of raising a certain sum, certain real problems remain.

1. *Jurisdiction and Double Taxation.*—The civilized world has accepted the ideas of subjective taxation, according to the capacity of the individual, before it has given up that of objective taxation, or the levying of tax upon a source of wealth wherever it is found. The two are in conflict, but the conflict does not much matter where the two are in the same tax or political jurisdiction. But where the object, say, is a ranch in the Argentine, and the owner a resident in England, then the Argentine government think most of the protection and benefits they are affording the ranch and without which the ranch would be unproductive, and think too of the wealth "withdrawn" from their country, while the British think of the wealthy private resident in their midst, who, compared with his neighbours, can "afford" in justice a high rate of tax. The people interested in the "ranch," as an object, may be the tenant, who has an occupational and capital interest, the owner who receives a rental and interest on capital, the mortgagee, and possibly a ground landlord—these may all be in different stations in life, properly taxable at very different levels, and resident in four different jurisdictions. Still more complex is the origin and destination of business profit—buying, and perhaps some manufacture done in Australia, blending and selling in Africa, the directing seat of control in London, the shareholders in America. How determine where profit is made? The widely distributed character of modern ownership accentuates the problem of double taxation. Neither Government is willing to give up an existing source of income. The matter is the subject of expert enquiries since 1920 by the League of Nations, the International Chamber of Commerce, and the various Governments. As an ultimate goal the choice of the individual as the crux of taxation rather than the physical object is now clearly preferable, and consequently the taxation of the resident on his whole resources wherever they come from, and the "reciprocal exemption of the non-resident" in the country of "origin" of the wealth or income is the generally approved principle in theory.

2. *Taxation of Collective Wealth in a Progressive System.*—Focussing attention upon the individual and his available resources leads to difficulty at a time when he has proximate resources held in collective form—*e.g.*, the reserves and undistributed profits of companies. When these companies are small groups of two or three persons, the distinction between personal ownership and collective ownership is very thin, yet very real. The aggregate of individuals' fortunes or incomes tends to be less than the aggregate of wealth or incomes finally accruing to individuals, to an increasing extent; it is not necessary to postulate the desire to evade highly progressive taxation as the cause.

3. *The Borderline Between Income and Capital Gains.*—The ease with which, under modern financial forms, income and capital are convertible into each other, and at the same time the fact that capital accretions may be due *either* to additions of unused income, *or* to new monetary expressions of the same thing, leads to great difficulties in "drawing the line."

5. The determination of "profits" as between two countries, where some of the trading operations are performed in the exporting and some in the importing country.

6. The establishment of customs tariffs which shall be fairly *ad valorem* without an unduly cumbrous and expensive administrative machine.

7. The reconciliation of "justice" in progressive taxation with social expediency and collective advantages in the accumulation of capital and preservation of incentive.

8. The choice of suitable articles of consumption for taxation which shall be wide enough to be productive of revenue and worth while, and which will not vanish through elasticity of demand or be repressive and regressive because they are necessary features in the poorest household budget.

9. At a time of very high expenditure the choice between finding objects of new taxation and putting fresh increments on successful existing taxes at a point at which those taxes are beginning to show their peculiar disadvantages to a marked degree. Akin to this is the super-imposition of various progressive types, which individually productive, eat into the yield of each other, *e.g.*, a combination of high income taxes, death duties, surtaxes and the Capital Levy (*q.v.*).

The Burden of Taxation.—In the last decade of the Victorian era a taxation budget in Great Britain in excess of £100 millions was regarded as the limit of prudent finance, with income tax at 8d. in the £. But the South African War, succeeded by social legislation, brought in clear view an annual budget of 200 million sterling, with an income tax of 1s. 3d. in the £, supertax and heavy death duties. In every budget debate it was asserted that the nation had reached the "limit of its taxpaying power," that it had "destroyed its war reserve," that it was "killing the goose that laid the golden eggs." Such jeremiads were uttered in the discussions of 1914 just before the World War. Every year of war enlarged the taxable horizon, and to-day the pre-war burdens, then so vast, seem trivial. There was much the same experience in other countries. To-day the annual payment in respect of the British debt to the United States alone requires a rate of income tax equal to the total for all purposes in pre-war times.[1] Of course taxation for the debt is the chief item in the post-war budget, equal in one case to nearly twice the total pre-war budget. In general, at a date sufficiently long after the close of the war for the position to have been consolidated, the debt situation can be even expressed as a percentage of 1913 and then as corrected by the 1921 wholesale price index number:—

	Debt in 1921 as percentage of pre-war debt 1913=100	"Corrected" debt in 1921 as percentage of debt in 1913 1913=100
Italy	+ 704·9	122·3
Belgium	+ 739·9	. .
France.	+ 919·0	266·2
United Kingdom . .	+1,079·8	596·6
Germany	+5,812·7	304·2

The proportions between local and central or national taxation vary greatly. Before the World War, say 1900, the United Kingdom had 119 millions sterling national, 56 millions local; France 3,100 million francs national and about 800 millions local; Germany 886 million marks imperial, 525 State and 800 communal; the United States, 505 million dollars Federal, 189 State, 706 local (total 1,400). In 1913–14, the figures were: United

Taxation per Head of Population in the United Kingdom 1913–14, 1914–15, and 1920–21 to 1925–26. Motor Vehicle Duties Excluded.
(From the Colwyn Report on Taxation and the National Debt)

	1913–14	1914–15	1920–21	1921–22	1922–23	1923–24	1924–25	1925–26
	£. s. d.	£. s. d.	£. s. d.	£. s. d.	£. s. d.	£. s. d.	£. s. d.	£. s. d.

Percentage relation of indirect to direct taxation .	74·0	66·4	47·2	60·7	56·7	59·5	51·2	53·7

4. The devolution of fortunes by gifts *inter vivos* instead of at death, bids fair to take a considerable corpus of "descending" wealth permanently out of the estate duty scheme.

[1]For the Paris agreement of 1929 *see* REPARATIONS. (ED. E.B.)

Kingdom 163 millions national, 93½ local; France 4,134 million francs national, 943 millions local; Germany 1,960 million marks Imperial, 1,140 State and 1,378 communal (total 4,478 millions); United States 661 million dollars Federal, 304 million State and 1,155 local (total 2,180). After the war (1924) United Kingdom 718 millions sterling national, 250 millions local; France 22 milliards national, 2½ milliards local; Germany in 1922 before the complete currency collapse, 447 milliards Imperial and about 200 milliards local; United States 3,355 million dollars Federal, 4,475 State and local, total about 7,830. (*See* Seligman: *Studies in Public Finance 1925*, p. 34.) These figures serve to show the great changes that have taken place in the relative positions of local and central taxation.

International Comparisons.—It is notoriously difficult to make statistical comparisons of the taxation burdens in different countries, so great are the differences in fiscal practices, but the following represents a very broad attempt (based upon figures before the Royal Statistical Society):—

Country	Unit of currency	1924-25 National income	1924-25 Total taxation	1924-25 Percentage ratio	1913 Percentage ratio
		(000,000's omitted)		%	%
England	£	3,850	852	22·1	11 4
France	Franc	170,000	30,293	17·8	13·8
Italy	Lira	100,000	20,000	20·0	8 6
Switzerland	Franc	5,000	750	15 0	6 9
Austria	Gold crown	5,000	872	17·3	16 0
Hungary	Gold crown	{3,600 / 4,000}	596	14-17	13·14

In France tax rates were subsequently increased and the percentage ratio brought nearer to the English. In Germany the estimate of national incomes was not very reliable, but the figure has been reckoned at 20 per cent. The yield of the taxes levied by the Great Powers in Europe thus represents about one-fifth of their national income.

In the United States the ratio between taxation and national income has recently been calculated at 10·5%, which is less than the pre-war charge in England, France, Austria and Hungary. There is probably no country in Europe in which the taxation is at present as low as in the United States.

But the computations of a more experienced American writer, Professor Seligman, are rather different. He reaches the following results, as the ratio of taxation to income *per capita*:—

	1900–01	1913–14	1918–19	1924–25
United States	7 76	6·68	10·03	11·06
United Kingdom	9·99	11·20	23·93	24 77
France	14 96	14·11	12·44	20·01
Germany	7·99	10·51	17·42	29·21

"The far higher taxation in France carried through in 1925 and the gradual reduction in Great Britain" are reversing the relative positions of the two countries, and it is possible that in the near future "the most severe tax burdens in Europe will be suffered almost equally by France and Germany. . . ." (*Studies in Public Finance 1925*, I. Corporation Tax Burdens, p 43.)

The European Burden.—Why is it that taxation in Europe amounts to such a large proportion of the national income? The reason is twofold: (a) State expenditure is still high; (b) the national income has not yet reached the pre-war level. "If we analyse expenditure, we find that in most countries debt service has risen enormously, and that certain terminal charges, such as war pensions and reconstruction outlay weigh heavily on the budgets; but that, on the other hand, appropriations for civil administrations and defence on the basis of pre-war prices are generally lower than in 1913." (Per Jacobsson in *Europa Year Book 1926.*) The Colwyn Committee on Taxation reported—that in reference to the post-war period up to the end of the last completed tax year, it could be said definitely that the burden of taxation was heavier in Great Britain than in any other European country, and very much heavier than in the United States.

It is small wonder, therefore, that taxation has come to be a dominant factor in economic life, although its importance in actually altering the standard of life, and reducing production and initiative can easily be exaggerated. The Colwyn Committee on Taxation reported that the burden of indirect taxation appeared formidable when viewed as a whole, but on analysis, it was found that the duties on food were now light except for the sugar duty, which they considered relatively high. The high level of the duties on luxuries appeared to be justifiable at present, considering the large amount of revenue required, and the risk of interfering too much with savings, if heavier direct taxation were adopted.

"The burden of direct taxation, while we do not wish to belittle it, is less crushing than is frequently represented. It does not, with trivial exceptions, enter directly into prices, and its indirect effects are not such as substantially to affect the general price-level." It has a materially adverse influence on capital accumulation, but this does not hold good, so far as the receipts are applied to payments on account of the internal debt. Again, it has widely diffused psychological effects, and has been responsible for a good deal of discouragement, while trade has been suffering from long-drawn-out depression due to wider causes; on the other hand, some of the psychological effects have been actually beneficial. The Colwyn Committee said that present taxation—even in conjunction with the loss of material wealth due to war expenditure, which lies behind the national debt—was not one of the main causes of industrial difficulty. (J. S.)

For details of the taxation systems of different countries *see* the articles under GREAT BRITAIN, UNITED STATES, FRANCE, GERMANY, etc.

F Shirras, *Science of Public Finance* (1924), E. R A. Seligman, *Shifting and Incidence of Taxation* (1921); *Income Tax* (1914); *Essays in Taxation* (1925), *Report of Royal Commission on the Income Tax* (1920), *Report* of the "Colwyn" Committee on Taxation and the National Debt (1927).

TAXATION, LOCAL. (The following article deals with the levying of taxes by authorities other than the central national authority.)

LOCAL TAXATION IN ENGLAND AND WALES

The principal function of the local authorities of England and Wales—these authorities comprise county councils, town councils, urban district councils, rural district councils, parish councils, and other bodies—is to provide and maintain the services which the State (*i e.*, the Central Government), without whose consent they cannot undertake any function, has either directed or authorized them to provide and maintain. The collection of money to pay for those services is ancillary to this principal function. The money so collected is, so far as it is collected by the State and contributed by it to local authorities, sometimes described as "national taxation applied to local purposes" or (less contentiously) as "national taxation applied in meeting part of the cost of services administered by local authorities." The whole of the money collected by local authorities themselves to pay for these services is sometimes described as being (or being obtained from) "local taxation"; more frequently the expression "local taxation" is applied only to that part of the money which is collected by local authorities, for public local purposes, by means of local rates; and it has been contended that whenever a local rate is described as "taxation" there should be some cautionary note to the effect that a local rate combines in varying degrees the elements of (i.) a compulsory payment for a service or services indispensable to the individual ratepayer and unobtainable by him, by his own effort, at a smaller price than is paid by him in the local rate, and (ii.) a compulsory payment for a service or services not indispensable to the individual ratepayer or obtainable by him, by his own effort, at a smaller price.

General Scheme of Local Finance.—The general scheme of local finance contemplates that the current expenditure of each financial year (including, in addition to the maintenance of the several services, interest on and provision for the repayment of

money borrowed on capital account) shall be met out of revenue.

The number of local authorities in England and Wales having financial transactions is about 11,000. A list of the principal services maintained by them is given in column 1 of the following table (Table A). Column 2 shows (in thousands of £'s), as illustrating the relative importance of the several services from the point of view of local finance, the amount spent out of current revenue by the local authorities on each of those services in a recent year (1925–6). Columns 3, 4 and 5 indicate how large a proportion of that expenditure was met from sources not being State contributions or local rates, from State contributions, and from local rates.

TABLE A

Services maintained by local authorities	Current expenditure of local authorities on each service	Specific income (other than from local rates) of local authorities in respect of each service: Fees, tolls, dues, rents and other receipts not being contributions from the state	Specific income (other than from local rates) of local authorities in respect of each service: Contributions from the State	Balance of current expenditure falling (for the most part) to be met out of local rates

Totals for services in Group III	*85,830*	*12,003*	*3,623*	*70,213*
Group IV.—*Sundry items appertaining to services mentioned above but not apportioned between them.*	12,950	6,383§	5,733§	834
Total current expenditure and current receipts of the local authorities of England and Wales (year 1925–26)	373,110	$\underbrace{138{,}918 \quad 84{,}683}$ 223,601		149,509

*Including sums levied, as water rates and otherwise, exclusively on consumers of water, for water supplied to them.

†These balances have been arrived at by setting gains in some localities against losses in others.

‡Includes alike the trunk roads between great cities, streets and minor roads in and between villages.

¶Includes destitute poor of many kinds, *e.g.*, those suffering from sickness, accident or infirmity, and their dependents, as well as those in receipt of relief by reason of unemployment or under-employment.

§These unapportioned receipts were not applicable wholly or mainly to the sundry overhead charges, amounting to £12,950,000, entered in column 2 but were applicable generally in aid of expenditure on services mentioned in column 1.

The table shows *inter alia* that, contrary to a widely-held popular belief, the current income of local authorities from local rates is much smaller than their current income from other sources.

Current Income Other Than from Rates and Government Grants.—There is (as already indicated) some difference of opinion as to whether the receipts—or some of the receipts—of local authorities from fees, tolls, dues, rents and other sources not being either rates for public local purposes or contributions from the State, should or should not be deemed to be derived from "taxation." Broadly stated, public opinion seems at the present time to regard them as being essentially of the nature of receipts for services rendered or commodities sold to individuals *qua* individuals and not as essentially of the nature of taxation Support for this opinion may be found in the fact that analogous receipts by the Post Office and by public utility companies from individuals for services rendered to them are not generally regarded as in the nature of "taxation."

Government Grants to Local Authorities.—The system of giving Government grants to local authorities originated in the years 1833–35. In the form in which it developed during the period up to 1888, it was a system of grants attached to specified items of expenditure, and the grants, while in terms described as in relief of local rates, in fact so operated as to stimulate expenditure on those items and to involve Parliament and the Government departments in the supervision in detail of some parts of the work of local authorities. This system, except so far as it related to elementary and industrial schools (most of which were at that time in the hands of voluntary bodies), was swept away by the reforms embodied in the Local Government Act of 1888, and, in lieu of it, there was set up a system whereby Parliament "assigned" to the county and county borough councils established by that act the revenues arising from certain national taxes and, at the same time, required those councils (in effect) to make payments to themselves and other local authorities in substitution for the discontinued grants The assigned revenues were made distributable to the councils through a special account, called "the local taxation account," on bases which were so designed as not to stimulate local expenditure. The yield of the assigned revenues was at the outset greater than the amount of the discontinued grants and there was an expectation that it would so develop as to keep pace with the normal growth in local expenditure In fact, the exigencies of national finance soon arrested the development of the assigned revenues system; annuities of fixed amount were substituted for most of the assigned revenues; periodical revisions which had been contemplated by the authors of the system did not take place; and the system, although still (1928) maintained in form, is regarded as having become obsolescent It now exists side by side with a great variety of *ad hoc* Government grants which reproduce many of the features of the pre-1888 system. Indeed, the number of these grants is so great and the conditions subject to which they are given are so various that it is impracticable to do more than briefly indicate the main facts.

The growth in the amount of Government grants relatively to the growth of the amount of local rates is shown in Table B.

TABLE B

Year	Government grants to local authorities	Amount of local rates in respect of all services—grant-aided and other	Total rates and grants	Proportion of such total received from grants
	Amounts, in thousands of £'s			%
1867–8	878	16,504	17,382	5·1
1885–6	3,650	26,143	29,802	12·3
1905–6	19,870	58,256	78,126	25·4
1925–6	84,684	148,598	233,282	36·3

Many factors have contributed to the increase in the percentage shown in the last column of this table. Among them may be mentioned: the imposition by the State of new duties (*e.g.*, education, housing) upon the local authorities; the insistence by the State upon the attainment of a higher standard of local administration than is deemed to be attainable without the giving of State assistance; the substitution, under the Agricultural Rates Acts, 1896 and 1923, of Government grants for proportions of the rates formerly payable by the occupiers of agricultural land; the progressive development of means of communication between the several localities, accompanied by the growth of a public opinion that certain services, formerly deemed to be predominantly of local interest, have become predominantly of national interest; and the prevalence of the doctrine that, at least in the case of the cost of such predominantly national services, the incidence of national taxation is, as between persons of equal income resident in different localities, more equitable than the incidence of local rates

It will be seen on reference to Table A that the amount of the Government grants in aid of the cost of the services constituting Group II. in that table was not far short of the expenditure falling to be met out of rates in respect of that group.

At the present time (1928) the proportion of the Government grants to local authorities which is distributable through the local taxation account has fallen to less than one-sixth of the whole amount of those grants. Upwards of five-sixths of that amount has been made by Parliament distributable either (i) on the basis that (subject to certain safeguards) the grant to a local authority in respect of a service shall be some prescribed proportion (or part) of the expenditure by the local authority on the service, or (ii) on some other basis which makes an increase in the amount of the grant depend directly or indirectly upon an increase in the expenditure on the service by the local authority. This system, it is said, inflicts hardship upon the localities not able to afford increases of expenditure and is over-generous to and stimulates expenditure in localities well able to afford such increases. Moreover, like the pre-1888 grant system, it involves Parliament and the Government departments to an increasing and undesired extent in the supervision in detail of some parts of the work of local authorities.

Rates for Public Local Purposes.—For the purposes of local rates for public local purposes, England and Wales have been divided by Parliament into rating areas, each of which is rated separately for the cost of the services administered therein by local authorities, so far as that cost is not met out of the receipts from fees, tolls, dues, rents, etc, and the Government grants already mentioned The expression "local rates for public local purposes" includes all rates levied by local authorities, except (i) certain land-drainage rates and unusual rates—amounting in all to less than ½% of the total amount so levied—and (ii) water rates levied only on consumers of water in respect of water supplied to them; and in the following part of this article the word "rates" must be read as meaning "local rates for public local purposes" unless the context otherwise requires

The number of rating areas is (in 1928) 1,804 This total comprises 29 metropolitan boroughs (including the cities of London and Westminster), 83 county boroughs (including cities such as Birmingham, Liverpool and Manchester), 255 municipal boroughs not being county boroughs, 783 other urban districts, and 654 rural districts. In each of these rating areas the council of the borough or district—a popularly elected body—is the rating authority, charged, to the exclusion of every other body, with the statutory duty of making and levying rates of sufficient amount to meet not only its own expenses, so far as they are payable out of rates, but such part of the expenses of every other local authority exercising jurisdiction within the area as may be payable out of the rates of the area

Rates are leviable on persons and not on property; but they are leviable only on persons occupying lands or buildings within the area rated or owning tithe rentcharge charged on such lands and buildings or enjoying rights of sporting or fishing in connection therewith. The short description of such persons is "the ratepayers," and the short description of such lands and buildings is "rateable hereditaments" or, more simply, "hereditaments."

In order that the total amount of the rate levied by the rating authority may be fairly apportioned among and assessed upon the several ratepayers in the rating area, Parliament has imposed upon the rating authority the duty of preparing periodically a

statement, called a "valuation list," in which each rateable hereditament in the rating area is shortly described, a "rateable value" is assigned to it, and the name of its occupier stated.

It is the duty, enforceable by penalty, of every occupier (and, in certain cases, of every owner or lessee) to assist the rating authority by furnishing such particulars relating to the hereditament as may be reasonably required for the purpose of ascertaining its rateable value. With the help of such particulars, and in the light of their own local knowledge and experience, supplemented, if need be, by paid professional advice, the rating authority decide the rateable value to be assigned to the hereditament. The entries made by the rating authority in the list are liable to revision by a separate authority called the assessment committee, which must, subject to certain conditions, hear any person or body aggrieved by any entry in or omission from the list. There is, also subject to conditions, a right of appeal from the assessment committee to the local Court of Quarter Sessions and, ultimately, on points of law, to the Superior Courts. In certain cases, matters in dispute may be dealt with by arbitration. The task of promoting by conference, and otherwise, uniformity of valuation throughout the several rating and assessment areas in each administrative county is entrusted to a county valuation committee representative of the various parts of the county.

The outline of the system of valuation for rating purposes given in the six preceding paragraphs relates, as from April 1, 1929 to the whole of England and Wales except London. In London an analogous but not identical system is in force.

The various kinds of rateable hereditaments are described in column 1 of the following table (Table C). Column 2 shows, according to a summary of estimates made by the rating authorities, the percentage of the total amount of rates levied in England and Wales in the year 1927–8 which was levied upon the ratepayers in respect of each of those kinds of property:

TABLE C

(Column 1) Properties in respect of which rates were levied on ratepayers	(Column 2) Percentage of total amount of rates levied (1927–28) in respect of each class of property	
Agricultural land		2·4
Mines and quarries	2·0	
Steel and iron works; Blast-furnace works; Smelting works	1·0	
Ship-building or ship-repairing works	0·3	
Mills and manufactories; Chemical works; Dyeing and Cleaning works (including laundries); and Workshops separately assessed and not elsewhere included	7·8	
Breweries and distilleries	0·3	
Land used as a canal or towpath for a canal; and Land covered with water other than reservoirs of waterworks	0·4	
Railways (including stations and appurtenances)	3·9	
Harbours, docks, piers, quays and wharves (except land covered with water included above)	0·6	16·3
Gas undertakings	1·4	
Electricity undertakings	1·4	
Waterworks	1·5	
Tramway undertakings	0·5	
Cemeteries and other burial grounds	0·2	
Sewers and sewage works and sewage farms	0·2	
Warehouses separately assessed	2·2	
Licensed houses (for the sale of beer, wine, spirits, etc.)	2·6	
Tithes and tithe rentcharges	0·7	
Land (not elsewhere included) separately assessed, including woodlands, parks, sports' grounds and rights of sporting	0·5	
Dwelling-houses, shops, offices, and all other classes of rateable property not mentioned above	70·1	81·3
Total (all classes)		100·0

When a rating authority has decided upon the amount to be raised by a rate, it brings that amount into comparison with the total rateable value of all the hereditaments in the rating area and, by means of this comparison (after appropriate adjustments, *e.g.*, in respect of amounts which cannot in fact be collected), estimates the amount which a rate of one penny per pound of the total rateable value of those hereditaments will produce. The total amount to be levied by means of the rate is then divided by the estimated produce of the penny rate, giving, as the quotient, the amount per pound of rateable value of the rate. The rateable value of a hereditament multiplied by this amount per pound (commonly called "the rate in the £") gives the amount payable by the ratepayer. That amount is in due form demanded, usually for a rating period of six months, from him by the rating authority, and thereupon becomes payable by him. In order to reduce the cost of collecting the rates, owners of property may in certain cases be required by the rating authority to pay to it rates otherwise payable by their tenants.

The average amount, per pound of the annual assessable value of all the rateable property in England and Wales, of all the rates collected therein, varied between 11s. 8¾d. and 12s. 10¾d. a year in the period of five years from 1923–4 to 1927–8. These amounts in the £ are equivalent to £3 13s. 3d. and £4 5s. respectively per head of the population of the country. The variation in the several localities from these national averages is very great. Thus, in 1927–8, the extreme range in the urban rating areas was from 7s. 6d. in the £ in a seaside pleasure resort to 34s. 4d. in the £ in a coal-mining area. In rural rating areas the range was similar but on a somewhat lower level.

The congeries of systems, outlined in the preceding paragraphs, which together constitute the local taxation system of England and Wales, have been evolved in the course of centuries; the several parts of the system, and the system as a whole, are the outcome of many local customs, experiments, adjustments, conflicts and compromises—all ultimately expressed in general or local acts of Parliament or in votes of Parliament providing for grants from national taxation.

Abatements from Net Annual Value.—The causes which resulted in occupiers of lands and buildings (and not the owners thereof) being assessed to local rates and to the adoption of the net annual value of property occupied as the basis or standard of assessment, to the exclusion of any other basis, are stated in Professor Cannan's *History of Local Rates*. That basis has, however, been modified from time to time in cases where, by reference to the two canons of (i.) the ability of the ratepayer to pay and (ii.) the benefit derived by him from rate expenditure, the strict application of the basis of net annual value seemed likely to lead or had led to injustice. Thus, for the purposes of the Lighting and Watching Act of 1833—an Act which enabled parish authorities to undertake the lighting of streets and the provision of fire engines—it was deemed unjust to rate the occupiers of agricultural land on the same basis as the occupiers of dwelling-houses, and therefore Parliament (in effect) provided that, while the last mentioned occupiers should pay in proportion to the whole of the net annual value of the dwelling-houses, occupiers of agricultural land should pay in proportion to one-third (now one-quarter) only of the net annual value thereof. A similar plan was adopted in the case of the Public Health Act of 1848 (and is now embodied in the Public Health Act of 1875) under which, while the occupiers of dwelling-houses and similar properties contribute to rates for sanitary expenses in proportion to the whole of the net annual value of the property in their occupation, certain occupiers (*e.g.*, occupiers of agricultural land and land used as a railway or canal), who are deemed to derive but little advantage from sanitary expenditure, contribute (in effect) to that expenditure in proportion to one-quarter only of the net annual value of the land. The same plan was applied to certain rates (*e.g.*, rates for the relief of the poor, education and rural highways) in the Agricultural Rates Acts of 1896 and 1923 and the Rating and Valuation Act of 1925, with the result that occupiers of agricultural land have been liable to contribute, in respect of that land, to those rates in proportion to one-quarter only of the net annual value of the land.

The abatements made under the above-mentioned Acts of 1896 and 1923 were in respect of long-established rates, and consequently, if those abatements had stood alone, they could not have been made without increasing immediately the amount of rates payable by other classes of ratepayers; and with a view of mitigating (in 1896) or avoiding (in 1923) such an increase, grants in respect of the abatements were made from national taxation.

(G. W. B. M.)

The Rating and Valuation (Apportionment) Act, 1928, and the Local Government Act, 1929, provided for a very great extension, as from Oct 1, 1929, of this system of abatements Occupiers of agricultural land and agricultural buildings (not being dwelling-houses) are wholly exempted, in respect of such land and buildings, from all rates for public local purposes, and occupiers of industrial and freight-transport hereditaments, in respect of the parts of those hereditaments which are occupied and used for industrial and freight-transport (railway undertakings, light railways, canals and docks dealing with merchandise) purposes, contribute to local rates in proportion (generally) to one-quarter only of the net annual value thereof. The necessary provision for the "derating" measure was made in the Finance Act of 1928 These provisions are bound up with provisions for a reform of part of the existing system of Government grants (including the abolition of the Local Taxation Account) and for a great increase in the amount of those grants with the transfer to councils of counties and county boroughs of the functions at present exercised by Poor Law authorities, and with various reforms in the machinery of local government.

The provisions of the Local Government Act and the basis on which the new government grants to local authorities are calculated are explained *s v.*, LOCAL GOVERNMENT.

BIBLIOGRAPHY —The question of the real incidence of local rates as distinguished from the primary or apparent incidence was in 1897 referred to financial and economic experts by the Royal Commission on Local Taxation, which was then sitting. The replies were published in *Parliamentary Paper* [*C-9,528*] in 1899 That volume includes at page 55 a bibliography for the period 1833–97

Professor Cannan's *History of Local Rates in England in relation to the proper distribution of the burden of taxation* (1927) shows *inter alia* how local rates came to be assessed on occupiers of lands and buildings to the exclusion of the owners thereof and how the basis or standard of assessment came to be the annual value of lands and buildings to the exclusion of income from other sources.

Grice's *National and Local Finance in England, France, Belgium and Prussia* (1910) traces *inter alia* the growth of systems of Government grants in aid of the cost of services administered by Local Authorities It should be read in connection with the *Final Report of the Departmental Committee on Local Taxation in England and Wales* [*Cd 7,315*], which was issued in 1914, and with the *Statement* (prepared by H M Treasury) *of Government grants to Local Authorities in Great Britain, showing as far as possible the purposes for which they are paid and the bases of distribution in each case* [*Cmd 3,157*], which was issued in 1928.

The above-mentioned Report of 1914 deals *inter alia* with proposals to replace the rating system in whole or in part by a rate on land (or site) values, or by a local income tax, or by other revenue.

The Annual Local Taxation Returns (*England and Wales*), published (like all the official statements mentioned herein) by H M Stationery Office, exhibit in detail the working of the local taxation system. The Returns for each year are summarised in the Annual Report of the Ministry of Health and are summarized for a series of years (generally 1913–14 and each of the latest 14 years) in each issue of the Annual Statistical Abstract of the United Kingdom That Ministry also prepares an annual publication showing the rates in the £ levied in each urban area and in certain typical rural areas.

A Stationery Office paper, *Rates levied by Local Authorities* (*England & Wales*) shows for 1927–28, the amount of rates levied in respect of each of the principal classes of rateable property in each rating area.

See also *Ryde on Rating* (Butterworth & Co.) and supplements.

(X)

LOCAL TAXATION IN OTHER COUNTRIES

Some knowledge of the local government system of a country is obviously essential to the understanding of its method of local taxation. This is not the place for an attempt to explain, however briefly, local government systems, but it does seem necessary to allude to one or two characteristics which have a bearing upon the local taxation and in which the systems of other countries differ essentially from that of Great Britain

Europe.—The primary area of local government on the continent of Europe may be most conveniently described by the French word "commune." Almost invariably, the whole area of a country is divided into communes and these, whether urban or rural, whether large or small, have usually the same status and the same powers and duties. The only exception to this rule is that, in Germany and some other countries, certain of the larger towns are made independent of any other local authority, as is the English county borough of the county. The secondary area of local government, answering to the English county, is known as a "department" in France, as a "circle" in Germany, as a "province" in Belgium, Holland, Italy and Spain, and by various titles in other countries. It has usually a more organic connection with the commune than has the English county with the minor authorities, is more generally entrusted with control over these latter, especially in finance; and is looked upon rather as an agglomeration of communes for the wider purposes of administration than as having a separate existence of its own.

These two types of areas have each their elected local authorities with powers of local self-government, but side by side with these is to be found, almost invariably, a system of State local government, which may be carried on either by a completely distinct set of authorities or by employing officials of the local authority also as agents of the State. By this means the administration of the police is almost always completely withdrawn from the sphere of local self-government, the term "police" frequently signifying, not merely "security police" but the making and enforcing of any regulations (such as public health or building by-laws) whose infraction involves penal procedure Moreover, in the more completely centralized countries other matters than police are regulated locally by the central Government or its agents—as for instance, education in France, where, although local taxation is called upon to contribute to a certain extent to the expense, the whole cost of the salaries of teachers is borne by the central Government and does not appear in the local budgets

It follows from this that it is seldom possible to draw the same hard and fast line on the continent, as in England, between the purposes or the objects of national and local taxation, and that the whole conception of local taxation is different It is, indeed, held in some quarters that a system of local finance should, as far as possible, include all kinds of impositions which are found in the State system and be, in effect, a reduced reproduction of that system, in order that all taxpayers and all revenues may be called upon to contribute to the local charges In no country is this principle fully carried out, but there is almost everywhere a very close connection between the respective local and national systems This is especially the case in Germany since the World War. The various States of the German Confederation (or "Reich") have each the power to organize their own system of local government and finance, subject, however, to certain general rules laid down in the national constitution and by subsequent national legislation The general effect of these rules is that, in the hierarchy of Reich, States, provinces, circles and communes, the higher authority has the prior right to any sources of public revenue and the communes have to do the best they can with what remains to them after the superior authorities have made provision for their needs

The principal basis of the local taxation systems of the countries of the continent of Europe is to be found in the addition, to certain of the national taxes, of so many hundredths for local purposes ("additional centimes"), the whole of the tax being collected by the national authority and the produce of the "additional centimes" being paid over to the respective local authorities Thus, the demand note in respect of the land tax in France shows, in a specific instance, that 48% is what is called the "principal" (*i.e.*, the amount levied for national purposes), that 40% consists of "additional centimes" for the purposes of the department (which corresponds to the English county) and 12% for the purposes of the commune, which is the minor local authority

The number of centimes which may be added to any specific national tax by each type of local authority is definitely regulated by law—sometimes, as in France, by the annual finance act, sometimes for a period of years or until fresh regulations are laid down. The French national taxes to which centimes may be added for

municipal purposes are the four "direct contributions" ("direct" taxes in the continental sense meaning taxes which are levied upon a person in consequence of his name being inscribed on a cadastre or register), viz., the land tax, the land and buildings tax, the tax on the rentals of houses and apartments, and the licence tax on trades and professions. In Germany, before the World War, the addition of centimes to the income tax was the main source of revenue to the communes. This is no longer permitted, the total yield from the income tax being now taken by the Reich, which refunds a certain proportion to the States and communes. The communes are still allowed to add percentages to the State taxes on land and buildings and on professions, in which the Reich has no part. In most of the other countries of Europe the same system is to be found to a greater or less extent.

In all European countries, the communes, whether or not they may add centimes to the national taxes, are given the power to levy certain taxes on their own account. Local taxes on land and buildings are very usual. So, too, is a dog or an entertainment tax. Other instances of local taxes are—in Belgium, on visitors, street façades, construction or reconstruction of buildings, sale of liquor and tobacco; in France, on dwellings and offices, horses, carriages and motor-cars, sports grounds, domestic servants, pianos and organs, billiard tables, clubs; in Germany, on unearned increment, acquisition of land, musical instruments, sale of beer; in Switzerland, by way of bicycle, motor, hunting and fishing licences; in Czechoslovakia, on house rents, lodgers, vacant land, advertisements. In Estonia there are no less than 30 heads of taxation which are open to the local authorities, and in Hungary the towns may levy taxes on any object which is not taxed by the State. In Spain, in addition to a number of local taxes of various kinds, a municipality may levy a general tax on every resident based on his financial condition. In spite, however, of the variety of local taxes of a miscellaneous character, their yield is everywhere a small proportion of the total revenue of the local authorities.

The levy of a local income tax is of greater importance and deserves special mention. The countries in which such a tax (independent of any national tax) forms one of the chief sources of revenue are Denmark, Finland, Holland, Norway, Sweden, and some of the cantons of Switzerland. In Holland, in 1924, there were only five communes which levied no kind of income tax for local purposes. In that year 60 communes added percentages to the national income tax, 85 levied a local non-progressive income tax, 309 levied a similar tax as well as adding percentages to the national tax, and 625 levied a local progressive income tax. The assessment of each taxpayer, in Holland, to the local income tax (if any) is fixed by State officials at the same time as that to the national income tax, and the tax is collected by State officials and paid over to the communes on a certificate by the minister of finance. Power can, however, be given by royal decree to a commune, for a period of not more than five years, to deal with the local income tax through its own officials. It has already been mentioned that the power which the German communes formerly possessed of levying a local income tax by means of additions to the national tax has been taken from them. The system was, however, so complete until the changes made subsequently to the World War that reference should be made to it.

Formerly the "octroi"—local customs duty on articles of consumption—was one of the main sources of revenue to the municipalities on the Continent, but it has now been abolished in the majority of countries and is of importance only in Italy and France. In the latter country, an act of 1897 encouraged the communes to suppress their octrois by opening out to them other methods of local taxation, and later acts have pursued the same policy. As a consequence many French towns have abolished the octroi altogether, while others have contented themselves with reducing the rate of duty or the number of articles subject to it. The total number of octrois in France, which was 1,552 in 1913, was reduced to 1,100 by Jan. 1, 1926, and continues to diminish. Apart from the addition of centimes to national taxes and the direct imposition of local taxes, such charges as those on frontagers for street cleaning or on occupiers of houses for the removal of refuse are often found reckoned as items of local taxation.

In many countries the system of assigned revenues, in conjunction with that of local taxation, is in force and in Germany in particular, since the war, this system has been largely extended. Government grants, also, are frequently given for specific purposes. It may further be mentioned that local taxation is, on the Continent much more than in England, relieved by the income arising from municipal landed property, especially forests, and that in some countries the profits from the municipal supply of gas or electricity and from other municipal undertakings, such as tramways, slaughter-houses, markets, funerals or quarries, add substantially to the local revenue. The larger (county or provincial) authorities, as a rule, obtain their funds by percentage additions to certain specified national taxes and by the method of assigned revenues. They may also, sometimes, levy taxes themselves, but in this they are never given the same scope as the communes. Thus, in Belgium, taxes on dogs and bicycles are levied by almost all the provinces, and on motor-cars and persons employed in industries by several. In Spain is to be found the exceptional system of the provinces making additions, for their own purposes, to municipal taxes. In some countries the method of obtaining provincial revenue is by precepts on the communes.

Whereas the local authorities in continental countries possess a greater variety of sources of revenue than in England, they are, generally speaking, much more restricted as to the amount of revenue which they may raise by taxation and that not only by definite statutory provisions as to the number of centimes which may be added or the subjects of local taxation. In many continental countries the annual estimates of every local authority require the approval of a higher authority and, even where this is not the case, the levy of a new tax will almost always require such approval. In Denmark approval is required only when the local taxation exceeds a certain amount; in Sweden and in several of the Swiss cantons control of this description is little more than formal, and in Estonia and Finland the local authorities possess almost entire freedom within the limits of the law. On the other hand, both in France and Germany, and in the countries which closely follow either the French or the German model, the higher authorities in the hierarchy of government exercise a general control over the finances of the lower. This control may not, indeed, be limited to the refusal to sanction taxation proposals of the local authority. The system of *inscription d'office*, which is recognized in France, Holland, Poland, Hungary and some of the German States, enables the superior authority to insert in the communal budget items for obligatory functions, which may involve additional taxation.

In some countries a department or official of the central Government exercises this control directly over all local authorities; in others this applies only to the highest grade of local authority, which may itself control the lower. Thus, in France, the prefect, who is an official of the central Government, controls both the department (=county) to which he is appointed and every local authority within it. In Holland the annual budget of the communes requires the approval of the provincial executive, from which there is an appeal to the Crown. In Spain there is in each province a body representing the central Government, whose approval is required for the levying of all local taxes. In Czechoslovakia the provincial authority sanctions the levying by the communes of any of the taxes on the recognized list, but the permission of the Government is required for the levying of any others.

Valuation and assessment for land, buildings or income taxes are usually the concern of the national authorities. Indeed, a French writer (M. Roger Bonnard) postulates it as one of the essential conditions of local impositions that they must be such that their assessment and levy can be carried out by the State services, since the majority of the local authorities are not in a position to exercise these functions. On the other hand, the contrary system is to be found. Thus, in Denmark, an assessment committee is directly elected annually in each commune and in the towns assesses for national as well as local taxes. There is an appeal from this committee to a county liabilities council as regards assessments on real property. Although, as a rule, the

final accounts as well as the estimates of each local authority must be submitted to a superior authority, there is nowhere to be found the same systematic Government audit which is carried on in England and Wales under the Ministry of Health.

British Overseas Dominions.—Local government and local taxation in the self-governing Dominions of the British Empire resemble the British system rather than the continental, but in one respect the method of local taxation differs from both, in that it is very generally based on the capital value of land. Thus, in Australia the main source of municipal revenue consists of rates levied on the unimproved capital value of land in New South Wales and Queensland, on the annual value of land in South and Western Australia and, in Victoria, on either the one or the other at the option of the local authority. It is to be observed, however, that in Western Australia the annual value of a property, for purposes of taxation, must be taken as not less than 4% of the capital value of improved or 5% of unimproved property, and in South Australia also there is a similar check on the annual value, which approximates it to a capital value tax.

The position is much the same in the other Dominions, the precise selection between annual or capital value of land and buildings, or land value alone, being a matter, primarily, for legislation by the various provinces, and secondarily for the decision of the local authorities themselves. In most of the provinces of Canada buildings are taxed as well as land, while personal property and businesses are also in some cases subject to local taxation In Nova Scotia, Ontario and Saskatchewan municipalities may levy a local income tax, but this power has not been widely exercised Market dues, dog taxes, liquor, trade and vehicle licences are available to the local authorities in the Dominions generally. Grants from the central Government do not play so large a part in the Dominions as in Great Britain, nor is central control exercised to any great extent, except as regards restrictions on the raising of loans. In British India provincial rates are levied on the annual value of land, while the principal sources of municipal revenue are octroi, taxes on houses and lands, animals, vehicles, professions and trades, tolls on roads and ferries, and water, lighting and conservancy rates.

Bibliography.—P Ashley, *Local and Central Government*, a comparative study of England, France, Prussia and the United States (1906); J Watson Grice, *National and Local Finance*, a review of the relations between the central and local authorities in England, France, Belgium and Prussia, during the 19th century (1910). LOCAL TAXATION IN THE UNITED STATES

State and local taxation in the United States varies greatly from State to State, and there are practically as many systems as there are States and territories. The State Constitutions provide the outline of the system The States control by general laws all taxes levied by their political subdivisions, the counties, cities, towns, school and other districts; the State and local taxes may be therefore explained together.

The general property tax is the chief source of State and local revenue in the United States It is used in every State and Territory In all but a few States it affords revenue for the State and for all of its political subdivisions as well. In a few States the State Governments draw little or no revenues from this source depending on other taxes which are, however, sometimes only modified forms of the property tax. This tax has an unbroken historical existence from the earliest colonial days down to the present. It began when the people in the towns of New England or in the counties of Virginia and other southern colonies were confronted with the necessity of raising money for some common purpose such as the building of roads and bridges, or later the support of schools. The original idea was that each resident should contribute to the common fund in proportion to his ability. In measuring ability the simplest of rules were followed Thus the assessors, officers appointed to apportion the taxes, counted up or "listed" the number of acres of land owned, as so many acres of arable land, so many of pasture, woodland and swamp, the number of cattle and houses, and "listed" also all other property such as houses, barns, furniture, etc. Since, obviously, one cannot add together such items as 20 ac. of land and five horses without some common denominator, values in money were attached to the "list." At first these values were quite arbitrary, but as time went on an effort was made to make the assessed or "listed" values correspond to the selling or market values of the property. People who earned a living from trades or professions were often "listed" or "rated" at arbitrary sums for their "faculty" or ability to pay, based on some rough estimate of their earnings Sometimes heads or polls were similarly listed as property at an arbitrary value of, say, $100, the resulting tax being, perhaps $1.00

As the tax developed it became, during the first part of the 19th century, a personal tax, the amount of which was to be determined in each case by the taxpayer's "estate," that is, in proportion to everything he possessed. But as time passed and the forms of ownership became complicated, as, for example, mortgages owned by one person, secured by another person's property, or stocks, bonds and contracts of many sorts, the tax became less and less personal. The present fundamental idea is that the tax is levied upon ownable things, rather than on the owners thereof But traces of the old idea are still to be found. The result is that the tax, especially as used by the local governments, is primarily a tax on tangible property That means that it is a tax on all real estate within the taxing jurisdiction and on such tangible personal property, as furniture, stocks of goods and merchandise, as can easily be found In many States intangible personal property, such as money due to a person, stocks, bonds and the like, is taxable according to the letter of the law either as all other property is taxed or at lower rates. But inasmuch as such property, in practically all cases, merely stands for and represents other property which is fully taxed, its owners resist every attempt to assess it, and since it is intangible and hence easily concealed, very little is ordinarily placed upon the rolls

Since probably 85% of this tax is on real estate and physical property of a similar visible sort, a description of the tax as applied to this class of property will be given. Each State is divided into assessment districts. In New England, originally, the township was the district, in Virginia it was the county, and in cities it was the old "ward" The nature and size of the assessment district is a matter determined by the framework of government and hence varies from State to State In each district there is an assessor, or sometimes a board of assessment. Where the districts are small, as a single township, or a ward in a city, the assessor can complete the list or roll in a few weeks But the work, to-day, requires considerable judgment and discretion and is best done when the district is large enough to warrant the employment of a full time assessor with a staff of trained deputies.

The Assessor's Work.—In a typically, fully equipped, large assessment district, this consists, first, in the preparation of a set of maps, or, in cities, of block books, showing each piece of real estate The next step is to ascertain, from sales, and other sources, the fair market value of the property and by comparison of adjacent or otherwise similar properties to fix uniform or equal valuations. These valuations are then entered in the general assessment roll opposite a description of each piece of real estate or other property and each owner's name is noted. In most States every property owner is required to file a statement or declaration of his property. These declarations are not very important so far as the real estate is concerned for that is all on record in the assessor's office. But they serve, when checked by inquiry made by the assessor's field deputies, to give information as to the personal property.

The assessment roll, sometimes called the assessment list, or the assessment book, in which the taxed properties are entered at the values fixed by the assessor, is a formidable public document of many pages and often in many volumes, and when completed serves as the warrant for the collection of the taxes, and finally as a record of taxes paid The roll is written anew each year and

the entries are always revised for changes in ownership, new buildings, changes in personal property and the like, and, as often as may be necessary, is completely revised as to the land values. It is customary to assess all property for much less than its full market value, although in almost every State the words of the law direct the use of full value.

Review or "equalization" of the roll after the assessor has completed his work consists, in the main, in allowing taxpayers who feel that their property is too heavily assessed to have a hearing before some board, usually the county governing board or the city fathers, called a board of review or of equalization. After this review the roll passes to the auditor who extends the taxes, showing how much each person is to pay and then to the tax collector.

The rate of the tax is expressed as so many mills on the dollar of assessed value, or as so many cents or dollars and cents per 100 dollars. Thus a tax of 10 mills on the dollar is equivalent in the other form to $1.00 on the $100. The rate is arrived at in one of two ways. The most common method is to estimate first how much money will be needed to run the Government for the year, and then to divide that sum by the total of the assessment roll, thus getting the tax rate. But naturally the total to be raised is seldom fixed without attention to what the resulting tax-rate will be. The other method is to fix rates for each activity of government as: 5 mills for schools, 2 for roads, 1 for the hospital; or for each branch of government as: 5 mills for the county, 2 for the village or district, 5 for the State; and then to require or attempt to require that each activity confine its expenses to the amount of money these rates will yield. In some of the states where all branches of government, from the smallest school district or village through the towns and cities, and the counties up to and including the state itself, levy on the general property tax the rate applied to any one taxpayer is a combination of three or more tax levies, the state, the county, and as many local districts or divisions as include his property. Thus a common occurrence would be about 50 cents State tax, 50 cents county tax, 75 cents town or city tax, 25 cents primary school district tax, and 10 cents high school district tax. Many more may occur.

Cities sometimes make an assessment of the property within their boundaries in addition to and separate from the assessment made for the other branches of government. This is most often the case where the assessment roll for all other branches of government is a county roll. The valuations on the two rolls do not usually agree. In fact the city roll is apt to show higher values because the main reason for incurring this otherwise wasteful cost is to obtain a lower tax rate. This is a bit of camouflage, because if the tax I have to pay on a house worth $10,000 is $100, it makes no difference to me whether it is computed as $1.00 per hundred on $10,000 assessed value, or $2.00 per hundred on $5,000 assessed value.

Equalization of Assessments.—Equalization between districts becomes of great importance whenever several different branches of government levy heavy taxes on the same roll. Equalization between individuals in the same district is, as indicated above, generally left to a local board. At one time, when the State's government expenses were relatively small, the State's needs were apportioned roughly to the districts, which then collected enough money in addition to their own needs to cover this charge. But as the State activities grew and the State's share became large, let us say as much as 50 cents on each $100 of assessed value, it made a serious difference if one locality or district had a low valuation and another a high one. So State boards of equalization were established which raised or lowered any district assessment roll which seemed to be out of line with the others. This proved a crude remedy and to-day in many States there are State tax commissions among whose duties it is to supervise and direct the work of the local assessors all the time. The object of this supervision is to make the assessments uniform.

The general property tax is most successful where there are mainly neighbourhood charges to be apportioned among neighbours. But when, among the taxpayers, there are great corporations owning property, such as railroad lines, electric light and power plants, extending through many assessment districts, local piecemeal assessment becomes difficult. Hence has arisen the practice of taking the assessment of all public utility companies, financial institutions such as banks and insurance companies, and some other large corporations, out of the hands of the local assessors. These are then either assessed centrally as units by the State tax commission and the assessments apportioned to the districts, or the taxes from these sources are taken over entirely by the State. In the latter case the methods may be changed and the tax based on gross receipts or some other factor. When that is done the amount of the State taxes to be apportioned to the localities is smaller. In several States the taxes on the segregated classes of property supplemented by other taxes have been sufficiently large to reduce the State's share of the general property tax to nothing or to a very small amount.

Exemptions are an outstanding feature of the property tax. Property used for religious worship, for educational and charitable institutions, and cemeteries is universally free of taxation. Veterans of war are often given liberal exemptions, especially if possessed of only small amounts of property. Very often a small amount of household furniture, tools, etc., is allowed as an exemption to everybody.

Miscellaneous Taxes.—*Poll taxes* come next to the general property tax in age but are slowly passing into disuse. Among the origins of these taxes was the idea that all able-bodied men should go out for at least a few days each year and work on the roads. Those who could not or did not want to do so could pay a tax in lieu of work. But there was, also, the idea that everybody should pay a little, be it only a dollar a year, to support the Government under which he lived. Poll taxes have been used as above for roads, and also for schools, hospitals, in commutation of service in the militia and occasionally imposed on special classes such as "foreign miners." But the trouble and cost of collection and their inherent inequality has led to their abandonment in many places.

Licence taxes on selected businesses and occupations are extensively used. These are annual charges on the privilege of doing business of the kinds selected for taxation, and payment is shown by a "licence" which reads as if it granted a privilege. The classes of business selected are frequently those which use comparatively little property covered by the property tax. But that criterion is not carefully applied. In the southern States the licence taxes are very numerous and long tariffs of rates covering hundreds of classes of licenses are enacted.

Income taxes have come into use in several of the States. There are now eleven States with some kind of an income tax enacted mainly since 1911. In Wisconsin and Massachusetts the income tax was introduced as a sort of substitute for the taxation of intangible personal property under the property tax, which, as explained above, is not satisfactory anywhere. In those States the tax is centrally administered but the proceeds are distributed in part to the localities. In New York the income tax is a part of the programme of supporting the State Government with as little recourse to the general property tax as possible. Other States have income taxes which vary greatly in form and purpose. In general the rates are graduated but not very high, and the personal exemptions much smaller than in the federal income tax. In some States the tax falls on corporations as well as individuals.

Inheritance taxes, or corresponding death duties, are used in very nearly all the States and are State taxes, not local taxes. In a few States there are estate taxes which, like the federal tax described above, fall on the entire estate of the decedent. But in most States these taxes are on the distributive shares received by the heirs and other beneficiaries. In these cases they are at rates graduated in two ways. (1) They are graduated by the relationship to the deceased. Thus the widow, or husband, the children or the father or mother are taxed lightly and have large exemptions. The brother or sister and the nephews or nieces are in a class taxed more heavily than the direct heirs. Cousins often form a third class with still higher rates and finally the heaviest rates and smallest exemptions apply to bequests to strangers to the blood. (2) For each class of beneficiaries the rates increase with the amount of property received. Difficulties of the gravest sort have arisen in the administration of these taxes when the

property left is scattered in several States. Gradually the following principles are coming to be, but are not yet fully, recognized: (1) real estate and tangible personal property are taxable where physically located; (2) intangible personal property is taxable only by the State in which the deceased had a residence.

Corporation or franchise taxes is a term applied to cover a great variety of taxes designed to reach more effectively than can be done otherwise, the tax-paying ability of the various classes of corporations They are in general aimed at the value of the business as a going concern and take on many different forms.

State finances, county finances, municipal finances and district finances, and hence the taxes used, are closely related and interlocking. The State very often subsidises and supervises the schools and the main highways The counties in many cases levy taxes for schools which are handed over to and expended by the school districts. The municipalities enjoy, possibly, a larger degree of independence than any other political subdivisions of the State, but that is only in the realm of strictly municipal activities. The total of taxes levied by any one class of taxing divisions does not correspond to the total expenditures of that class. Thus the State may be said to spend on its own activities very much less than it raises in taxes, for it subsidises many local expenditures. The counties subsidise the districts, but on the other hand receive subsidies from the State. The districts, school, road and other, and the municipalities are the final recipients of the subsidies from above, but levy some taxes of their own

BIBLIOGRAPHY.—The best sources of further information concerning taxation in the United States are. A *On statutory law*. The codes or general statutes of the United States and of the several States In many States the revenue laws are separately published. A digest of the revenue laws of the States is published at intervals of ten years by the United States Census Bureau, last edition, "1922" printed 1924 The Federal Government publishes the "regulations" for each of its taxes in a series revised as need be, and also the "rulings" and "decisions." These and other federal publications mentioned below can be obtained from the Government Printing Office, Washington, D C There are a considerable number of annual taxpayers' guides and continuous "tax services," relating especially to the Federal income tax, obtainable through the book trade.

B. *Financial statistics* The original sources are the reports of the State auditors or controllers and of the State tax commissioners. Secondary, but authoritative sources are· the United States Bureau of the Census series of publications entitled Wealth, Debt and Taxation, published in complete form once every decade, the last edition was "1922" published, 1924 The Bureau also publishes annually a report on the finances of cities Local taxes are frequently statistically summarized in the above State reports. The city taxation departments and the city auditors of the larger cities, also, usually publish annual reports. The New York City office is known as the Commissioners of Taxes and Assessments

C *Discussion, descriptions and studies* Most of the American college textbooks on public finance and the tariff and many legal treatises on taxation contain more or less extensive descriptions of United States taxes. The annual volumes of the *Proceedings of the National Tax Association* (vol. xx. 1927) contain carefully prepared papers and discussions on American taxation by the best qualified experts, and also, each year, a record of the more recent changes in tax law. The National Tax Association also publishes a monthly bulletin.

D. *Decisions of the Courts* contain very important matters concerning taxation. (C C. P.)

TAXICAB: *see* MOTOR-TAXICAB

TAXIDERMY, the art of preserving the skin, together with the fur, feathers or scales, of animals; a skin so preserved may then either be retained as a specimen for study purposes, or else mounted for exhibition in museums and private collections, or used as an ornament Formerly the setting up of animals used to be known as "stuffing," and, in most cases, this was actually what was done; the skin was simply stuffed with straw or wool until it looked something like the living animal. Nowadays, the stuffing process is quite extinct, the greatest care being taken to model the specimens so that they look as life-like as possible The old fashioned "bird-stuffers" have been replaced by taxidermists, and the verb "to stuff," as applied to the art of taxidermy, is now obsolete; the modern taxidermist "mounts," or "models" a specimen, not "stuffs" it The art does not appear to be a very ancient one, probably not more than 300 years old; this statement only applies to the stuffing or mounting of specimens, as, of course, the curing of skins, for use as wearing apparel, rugs, etc., must have been perfected in very early days. Taxidermy, in a crude style, was practised in England towards the end of the 17th century, as is proved by specimens in the Sloane Collection, which in 1753 formed the nucleus of the British Museum. At the Great Exhibitions held in the middle of the 19th century, many examples of British taxidermy were exhibited; at the Paris Exhibition of 1864 a special zoological section was prepared by Mr. Edwin Ward. The much higher standard of the exhibits in the great museums, and the demands of sportsmen for the proper treatment of their trophies, have transformed the "stuffing" of animals into an elaborate art.

All the early books published on this subject*, such as R. A. F. Réaumur's *Treatise* (1749) and the *Guides* and *Instructions* on collecting and preserving natural history specimens, by E. Donovan[1], W. Swainson[2], Captain Thomas Brown[3], are now quite out of date, and only interesting from an historical point of view. For work in the field the instructions issued by the British Museum of Natural History[4], and Rowland Ward's[5] Sportsman's Handbook, are of the greatest assistance to the sportsman and collector. As regards the actual mounting, the work is so intricate and requires such special training, that it is rarely undertaken with successful results by amateurs A few works have been published dealing with this branch of taxidermy and the reader will find much that is helpful in William T. Hornaday's[6] account of American taxidermic methods.

Taxidermy may then be considered under two quite separate headings, (1) the skinning and preserving of specimens, (2) the mounting of such specimens in as life-like a style as possible It should be noted that only a very small number of the animals skinned and preserved are set up, or mounted; the great majority go to swell the large study collections now maintained in museums.

Tools Used.—The knives and other tools used in skinning an animal are the following:—a series of scalpels, forceps and scissors, scissor-forceps, pliers, small bone-saw, brain-scoop, a variety of scrapers, a camel-hair brush, and a set of glovers' needles. As regards preservative for use on the raw skin, arsenical soap may be used as long as proper precautions are taken; Rowland Ward's Taxidermine is a useful and effective, non-poisonous preparation, as it may be used on both sides of the skin in cases where the fur is "slipping," that is, tending to come away from the pelt In no circumstances should the skins be exposed to the direct rays of the sun, and alum, frequently used on large mammals, should never be employed on the skins of birds as it makes them brittle If nothing better is to hand large skins can be cured with wood-ashes, the harder the wood, the better the ash; this is how many native-cured skins are prepared, and doubtless was how primitive man treated skins before soft-dressing them Some good results have been obtained by using common salt; this process is one, however, which necessitates most careful attention, and is not to be recommended in moist climates, as the skins will not dry well and are liable to sweat. Skins of large beasts may be preserved by pickling; they are first thoroughly treated with salt and afterwards immersed in a barrel of brine Reptiles and fish can be preserved with Taxidermine in the same way as mammals and birds, or they may be placed in spirit and brought home entire.

A most important point is the packing of skins for transport; the skins should be packed with plenty of naphthalene, and, in the case of large mammals, turpentine may be used to protect the skins against insects The latter spirit should not be used indiscriminately on bird-skins, as it dissolves the fat in the skins and this will adversely affect the colour and condition of the plumage.

Procedure with Mammals.—With mammals, whether they are required for study or mounting purposes, operations must begin by measuring the dead animal while still in the flesh; head and body, tail, ear, and hind foot must be measured, in feet and inches for large beasts, in millimetres for medium-size and small mammals. Then comes the important item of writing the label for the skin; the measurements just taken should be entered on one side of the label, together with such field notes as may be desirable. On the other side the date and locality of capture, sex and

*The superior figures placed after authors' names have reference to books mentioned in the bibliography.

collector's number and name, must be recorded. A second label should be prepared giving the collector's initials and number, for attaching to the skull when freed from the body. In skinning a large animal, such as a tiger, care should be taken to conduct the whole operation in the shade; if no shade is available a tent should be pitched. The body is then slit up from the edge of the lower lip to the tip of the tail, and cross cuts are made from this median incision along the limbs to the feet. The skin should be removed as cleanly as possible, all fragments of fat or muscle, must be removed with the body, and not left on the skin; otherwise the hair will tend to slip at the spots where flesh remains inside. The nose, lips, eyes, paws, and ears require very careful and thorough skinning; the thick skin around the base of the whiskers should be scored so that the preservative can get well in, and the spongy tissue inside the pads of the feet should be cut away. The skin should then be well washed and hung up, hair-side out to dry. It should then be placed hair downwards on the ground, preferably on a mat, and gently pulled into correct shape and size. Then follows the application of the preservative, after which the skin is allowed to dry (out of the sun), and can then be folded up. Skinning a medium-sized, or small mammal is a slightly different operation, as here the only incision needed is a median one, along the abdomen; the limbs and head can be skinned out by simply turning the animal inside out. The limbs should be skinned as far down as possible and the bones of the feet severed from the carcase and left in the skin; occasionally the limb-bones are left in as well. The tail in most small mammals can be skinned by taking a firm grip of the base of the vertebrae and pulling the tail out of the skin; in medium-sized specimens it is frequently necessary to assist this operation with a ventral incision. The skin, after treatment with the preservative, is then moderately stuffed with wool, or wood-wool, according to the size of the animal, and a wool-covered wire inserted down the tail and up the body as far as the chest and head. After sewing up the body the specimen is pinned out to dry, with its fore and hind limbs stretched out parallel with the body, and the label tied on to the right hind foot. Care should be taken not to stretch a skin during these operations; an inexperienced person, with a heavy hand, can easily convert a five inch weasel into a ten inch one; on this account it is best to make the skin, as nearly as possible, the same size as it was before removal from the body, as indicated by the dimensions on the label. To skin the head of a horned animal it is necessary to make a transverse incision behind and between the horns, from the centre of this slit another cut is made down the back of the neck; the skin can then be removed leaving the horns on the skull.

Birds.—The skinning of birds is somewhat similar; the humerus, or upper wing-bone, is first broken; an incision is made either down the mid-line of the stomach, or under the wing, as far as the vent; the body is then skinned out by severing the legs, after stripping the bones, at the middle of the thigh-bones, and the wings are similarly treated, being severed at the fracture of the humerus. The head may often be approached through the skin of the neck; in some larger kinds it is necessary, however, to make a small dorsal incision in the neck. The eyes, muscles, and brain are then removed, and preservative and cotton-wool take their place. After cleaning the wings and treating the skin with preservative it is moderately filled with wool and sewn up. Care must be exercised in drying bird-skins, and paper bands, or cones, are frequently used to keep the feathers in position.

Reptiles.—Reptiles are treated much in the same way as mammals. With fish the incision is not made down the centre of the belly but along the less important side, from gill to tail. The skin can be manipulated neatly from each side of the incision; the fins should be severed from their attachments, but not too closely. Great care should be taken not to bend, or otherwise injure, the skin, during the removal of the body, as the scales are very fragile and easily detached. After treatment with preservative, the body should be filled with dry sawdust or sand, after which the specimen can be neatly sewn up; it may then be allowed to dry and the sawdust or sand removed in due course.

Mounting, in the second branch of taxidermy, that of mounting or modelling, it will be impossible in this article to give more than a brief outline of the intricate processes involved. A model, or "manikin," is built up to represent as nearly as possible the body of the animal, special care being lavished on the proper representation of the muscular system and veinage; the skin, which has been made as thin and pliable as possible, is then stretched over the model and sewn on in an invisible manner. Frequently additional realism is produced by covering the "manikin" with a thin layer of modelling composition, so that the skin may be moulded to the desired form.

TAXIMETER, a registering apparatus which records the fare for the hire of a hackney carriage or motor taxicab. It is put into service by the movement of a handle, and is operated by one of the front wheels of the cab. The parts are indicated in the diagram. The star-wheel is driven from a hub-ring attached to the near-side front wheel of the vehicle. A flexible shaft leads away from the star-wheel to the gear-box fixed under the meter. This box enables the speed to be geared down, and also allows of the substitution of different gears with teeth suitable for the circumference of the tyre in use. Behind the meter is the clock winder. To put the meter into service the tariff disc handle is turned as far as it will go, and the flag pushed down. The meter will then register by time and distance. For the "stopped" position the tariff disc handle is again turned as far as it will go; registration is then only by time. When the "extras" handle is turned the "extras" will show in the aperture.

A double tariff meter is so constructed that the driver can turn on either the day or the night tariff, and the meter is arranged in such a manner that only half the normal distance is given for

THE EQUIPMENT OF THE DRIVE, GEAR CHANGE AND METER SHOWN FROM THE REAR

the same amount of fare. Another type is made to show a higher fare for the first mile, and then a lower basic rate subsequently.

TAY, the longest river in Scotland. From its source in Ben Lui (3,708 ft.), a mountain on the borders of Perthshire and Argyllshire, it flows north-east to Logierait, where it curves to the south by east as far as Dunkeld; there it turns south-east to the mouth of the Isla, where it bends south-west to the vicinity of Scone. From this point it makes a sharp descent south-east beyond the county town, where it sweeps to near Newburgh in Fifeshire; here it faces the north-east again as far as Broughty Ferry, whence it flows straight eastwards into the North sea, off

Buddon Ness in Forfarshire, after a total run of 117 miles. During the first 11 m it is known as the Fillan and discharges into Loch Dochart. From the lake it emerges as the Dochart (13 m), which enters Loch Tay at Killin Flowing through the loch for 14½ m. it issues at Kenmore under its proper name of Tay. With its tributaries it drains all Perthshire and portions of Forfarshire and Argyllshire, having a catchment basin of 2,400 square miles. In many parts the current is impetuous, and in flood has occasionally wrought much havoc. Its mean discharge of water every minute is estimated to be larger than that of any other stream in the United Kingdom.

Vessels make Dundee at all stages of the tide, and the estuary is navigable to Newburgh by vessels of 500 tons, and as far as Perth by ships of 200 tons. The navigation, however, is seriously obstructed by shifting sandbanks. The estuary varies in width from ½ m. at Cairniepier Ferry to full 3 m. at its mouth The first railway viaduct across the firth, opened in 1877, was blown down along with a train in 1879 The second bridge, 2 m and 73 yd. in length, was erected 60 ft higher up stream and opened in 1887. The Tay is famous for salmon.

TAY, LOCH, the largest lake in Perthshire, Scotland. It is situated about the middle of the county and has a flattened ogee form, with a general trend from north-east to south-west. It is 14½ m long from Killin at the head to Kenmore at the foot, from ½ m to fully 1 m. wide. It receives at Killin the rivers Lochay and Dochart and discharges by the Tay at Kenmore Ben Lawers (3,984 ft) rises near the left bank There are piers at Killin, Ardeonaig, Lawers, Ardtalnaig, Farnan and Kenmore, at which the steamers call during the tourist season. At the foot of the lake is an island containing the ruins of the priory which was founded in 1121 by Alexander I. in memory of his wife Sibylla, daughter of Henry I She was buried here Loch Tay enjoys great repute for its salmon-fishing.

TAYABAS, a municipality (with 48 *barrios* or districts) of the province of Tayabas, Luzon, Philippine islands, about 8 m. north of Lucena, the provincial capital. Pop. (1918), 14,983. Tayabas, which was the provincial capital from the middle of the 18th century until 1901, is situated on the slope of the extinct volcano, Banájao, and commands a fine view of the surrounding country The chief agricultural products of the region are rice and coco-nuts Hat-making has attained to considerable importance. In 1918, Tayabas had 8 manufacturing establishments, 6 rice mills, and 530 household industry establishments, with outputs valued at 26,400; 260,000; and 88,000 pesos respectively. Of the 16 schools, 15 were public Tagalog and Bikol are the chief languages spoken

TAYGETUS, the highest mountain in the Peloponnese, separating Laconia from Messenia, and traversed by the steep Langada Pass. The highest point is H. Elias (7,900 ft.)

TAYLOR, ANN (1782–1866) afterwards Mrs. Gilbert and **TAYLOR, JANE** (1783–1824), English writers for children, daughters of Isaac Taylor (1759–1829), were born in London on Jan 30, 1782, and Sept. 23, 1783, respectively In 1786 the Taylors went to live at Lavenham in Suffolk, and ten years later removed to Colchester Jane was a lively and entertaining child, and composed plays and poems at a very early age. Their father and mother held advanced views on education, and under their guidance the girls were instructed not only in their father's art of engraving, but in the principles of fortification Ann introduced herself to the publishers Darton and Harvey by a rhymed answer to a puzzle in the *Minor's Pocket Book* for 1799, and Jane made her first appearance in print in the same periodical with "The Beggar Boy." The publishers then wrote to Isaac Taylor asking for more verses for children from his family, and the result was *Original Poems for Infant Minds* (2 vols, 1804–5), by "several young persons," of whom Ann and Jane were the largest contributors. The book had an immediate and lasting success.

They followed up this success with *Rhymes for the Nursery* (1806), *Hymns for Infant Minds* (1808, 2nd ed. 1810), *Rural Scenes* (1806); *City Scenes* (1809); a less-known collection, *Signor Topsy Turvy's Wonderful Magic Lantern; or, The World Turned Upside Down* (1810), and *Original Hymns for Sunday School* (1812). In 1813 Ann married a Congregational minister, Josiah Gilbert, and Jane went to live at Ilfracombe with her brother Isaac. In 1816 Jane returned to Ongar, where the family had been settled for some years, and died there on April 13, 1824. Ann Gilbert died at Nottingham on Dec. 20, 1866. Both sisters wrote after their separation, but none of their later works had the same vogue.

The best edition of the *Poetical Works* of the sisters is that of 1877. There is an excellent edition (1903) of the *Original Poems and Others*, by Ann and Jane Taylor and Adelaide O'Keeffe, edited by E. V. Lucas, with illustrations by F. D Bedford (1903)

Abundant information about Ann and Jane Taylor is to be found in: *Autobiography and Other Memorials of Mrs Gilbert* (2 vols., 1874), edited by her son Josiah Gilbert; *Memoirs and Poetical Remains . . . of Jane Taylor* ed. by her brother, Isaac Taylor (2 vols., 1825), and the collection by the same editor entitled *The Family Pen: Memorials . of the Taylor Family of Ongar*, vol. ii. (1867); *see* also Mrs H. C Knight, *Life and Letters of Jane Taylor*.

A selection of *Prose and Poetry* by Jane Taylor was published, with introd. by F. V. Barry, in 1925.

TAYLOR, BAYARD (1825–1878), American author, was born of English and German stock in Chester county (Pa.), on Jan. 11, 1825. He published at Philadelphia in 1844 a little volume, *Ximena; or The Battle of the Sierra Morena, and Other Poems.* Remuneration for his poetry on a scale generous for the time and advance payments for travel letters by the publishers of the *Saturday Evening Post* and the editor of the *United States Gazette*, as well as a conditional engagement by Horace Greeley, made it possible for him to take (1844–46) the coveted trip to the Old World which was his university education His study in Germany and his happy roaming through Scotland, England, France and Italy are described in his *Views Afoot* (1846), which went through a number of editions After a brief period of country journalism Taylor moved to New York city. The year 1848 brought him several lucrative magazine and newspaper offers, the most important of which was with the New York *Tribune*. The excitement of the gold rush at this period was responsible not only for his passionate Californian ballads but for his trip to the Pacific coast as correspondent for the *Tribune*, which he recounted in *Eldorado* (2 vols., 1850). The wanderlust was in his blood. His trips to almost every part of the globe continued till the end of his life, and, although the popularity of his narratives of travel has diminished, his vivid pictures of remote places, such as *A Journey to Central Africa* (1854) or *Northern Travel* (1857), in their day won many readers

For several years his lectures were equally in demand Quiet was afforded him in his country home, Cedarcroft, in which he entertained hospitably and read and wrote copiously. Some of the works of his later period are *The Poet's Journal* (1862), *The Picture of St. John* (1866); the translation of *Faust* (1870–71); *Home Pastorals* (1875); and the novels *Hannah Thurston* (1863), *Joseph and His Friend* (1870), and *The Story of Kennett* (1866). As a novelist Taylor is undistinguished; as a poet he is at his best in the *Poems of the Orient* (1854) or his rich and sonorous rendering of *Faust* in the original metres.

In 1862 Taylor had entered the diplomatic service as secretary of the legation at St. Petersburg, and in the following year he became *chargé d'affaires* at the Russian capital His disappointment at not being made minister there, which caused him to leave the service, was atoned for by his being made minister to Germany early in 1878. He died on Dec. 19, 1878.

Taylor's *Studies in German Literature* (1879) and *Critical Essays and Literary Notes* (1880) were published posthumously. Collected editions of his *Poetical Works* and of his *Dramatic Works* appeared in 1880. Besides co-operating with H. E Scudder in the publication of the valuable *Life and Letters of Bayard Taylor* (1884), Mrs. Taylor wrote an interesting volume of reminiscence, *On Two Continents* (1905). A. H. Smyth has a good biography (1896), with bibliography.

TAYLOR, BROOK (1685–1731), English mathematician, was the son of John Taylor, of Bifrons House, Kent, was born at Edmonton in Middlesex on Aug. 18, 1685. He was educated at St. John's College, Cambridge, and studied mathematics under John Machin and John Keill He obtained in 1708 a remarkable solution of the problem of the "centre of oscillation," which, however, remaining unpublished until May 1714 (*Phil. Trans.*, vol.

xxviii. p. 11), his claim to priority was unjustly disputed by John Bernouilli. Taylor's *Methodus Incrementorum Directa et Inversa* (London, 1715) added a new branch to the higher mathematics, now designated the "calculus of finite differences." Among other ingenious applications, he used it to determine the form of movement of a vibrating string, by him first successfully reduced to mechanical principles. The same work contained the celebrated formula known as "Taylor's theorem" (*see* INFINITESIMAL CALCULUS), the importance of which remained unrecognized until 1772, when J. L. Lagrange realized its powers and termed it *"le principal fondement du calcul différentiel."* In his essay on *Linear Perspective* (London, 1715, revised ed. 1719) Taylor set forth the true principles of the art in an original and more general form than any of his predecessors; but the work suffered from the brevity and obscurity which affected most of his writings.

Taylor was elected a fellow of the Royal Society early in 1712, sat in the same year on the committee for adjudicating the claims of Newton and Leibniz, and acted as secretary to the society from 1714 to 1718. From 1715 his studies took a philosophical and religious bent. Taylor died on Dec. 29, 1731, at Somerset House, and was buried at St. Ann's, Soho. As a mathematician, he was the only Englishman after Sir Isaac Newton and Roger Cotes capable of holding his own with the Bernouilli; but a great part of the effect of his demonstrations was lost through his failure to express his ideas fully and clearly. *See* also TAYLOR'S THEOREM.

See the lives of Taylor prefixed to his Contemplatio philosophica (ed. Sir W. Young, 1793), and to his *New Principles of Linear Perspective* (ed. Colson 1749).

TAYLOR, FREDERICK WINSLOW (1856–1915), American engineer, was born March 20, 1856, at Germantown, Pennsylvania. In 1875 he was apprenticed as pattern-maker and machinist in a small Philadelphia shop. As early as 1880 or 1881, while gang boss in the employ of the Midvale Steel Company, controversy with workers had led him to realize the necessity of accurate measurement of what constituted a day's work on any operation. This in turn led to a series of careful experiments resulting in important achievements in two fields; in mechanical engineering, the discovery with Maunsel White of a new method of tempering tool steel permitting metal-cutting operations at high speed (1898); and in the field of management, perfection of that system of shop management which later came to be known as scientific management. The remainder of his life was spent in forwarding the principles of this system, by practising the new profession of consulting engineer in management for many plants (1893–1901), lecturing, and writing.

He died on March 21, 1915, in the city of Philadelphia.

Taylor's writings include *Notes on Belting* (1893); *The Adjustment of Wages to Efficiency* (1896); *On the Art of Cutting Metals* (1906); *Shop Management* (1911); *The Principles of Scientific Management* (1911). *See* F. B. Copley, *Frederick W. Taylor, Father of Scientific Management* (1923); C. B. Thompson, *The Taylor System of Scientific Management* (1917).

TAYLOR, SIR HENRY (1800–1886), English poet and political official, was born on Oct. 8, 1800, at Bishop-Middleham, Durham. After a few months' service in the navy he obtained a clerkship ashore. From 1824 to 1872 he held important appointments in the colonial office, where he rendered active assistance to Sir James Stephen in drafting the Act of Emancipation. He died at Bournemouth on March 27, 1886. Taylor was the author of several plays, of which *Philip van Artevelde* was the most famous. His dramatic poetry is generally better than his lyrical work, but some of his lyrics, notably "If I had the wings of a dove" have found a place in many anthologies.

Taylor's *Autobiography* (2 vols. 1885) should be supplemented by his *Correspondence* (1888), edited by Edward Dowden. His *Works* were collected in five volumes in 1877–78.

TAYLOR, HENRY MARTYN (1842–1927), English mathematician, was born at Bristol on June 6, 1842. He was educated at Wakefield Grammar school and at Trinity college, Cambridge. He was appointed tutor in 1874, and remained on the mathematical staff at Cambridge until he retired in 1894. Taylor's work in mathematics was on geometry, but he is known chiefly for his effort to make scientific knowledge available to the blind. He lost his sight completely soon after he left Cambridge. He learnt Braille and transcribed a number of textbooks on mathematics, astronomy and geology. Hampered by the high cost of production of the books in Braille, he started a fund which the Royal Society accepted as a trust in 1913. Taylor died at Cambridge on Oct. 16, 1927.

TAYLOR, JEREMY (1613–1667), English divine and author, was baptized at Cambridge on Aug. 15, 1613. His father, Nathaniel, a barber, was a man of some education, for Jeremy was "solely grounded in grammar and mathematics" by him before he became a pupil of Thomas Lovering, at the newly founded Perse grammar school. Lovering is first mentioned as master in 1619, so that Taylor probably spent seven years at the school before he was entered at Gonville and Caius College as a sizar in 1626. He was elected a Perse scholar in 1628, and fellow of his college in 1633. He took holy orders in 1633, and, took the place of Thomas Risden for a short time as lecturer in St. Paul's. Archbishop Laud sent for Taylor to preach before him at Lambeth, and took the young man under his special protection. Taylor retained his fellowship at Cambridge until 1636, for Laud desired that his "mighty parts should be afforded better opportunities of study and improvement than a course of constant preaching would allow of," but he seems to have spent much of his time in London. In November 1635 he had been nominated by Laud to a fellowship at All Souls, Oxford, where, says Wood (*Athen. Oxon.*, Ed. Bliss, iii. 781), love and admiration still waited on him. He seems, however, to have spent little time there. He became chaplain to his patron the archbishop, and chaplain in ordinary to Charles I. After two years in Oxford, he was presented, in March 1638, by Juxon, bishop of London, to the rectory of Uppingham, in Rutlandshire. In 1642 he was appointed to preach in St. Mary's on the anniversary of the Gunpowder Plot, and apparently used the occasion to clear himself of a suspicion, which, however, haunted him through life, of a secret leaning to the Roman Catholic communion. This suspicion may have arisen from his intimacy with Christopher Davenport, better known as Francis a Sancta Clara, the learned Franciscan chaplain of Queen Henrietta; but was probably strengthened by his known connection with Laud, as well as by his ascetic habits. More serious consequences followed his attachment to the Royalist cause. The author of *The Sacred Order and Offices of Episcopacy or Episcopacy Asserted against the Aerians and Acephali New and Old* (1642) could scarcely hope to retain his parish, which was not, however, sequestrated until 1644. Taylor probably accompanied the king to Oxford. In 1643 he was presented to the rectory of Overstone, Northamptonshire, by Charles I. There he would be in close connection with his friend and patron Spencer Compton, 2nd earl of Northampton.

Taylor seems to have been in London during the last weeks of Charles I.'s life, and is said to have received his watch and some jewels which had ornamented the ebony case in which he kept his Bible. He had been captured while besieging Cardigan castle on Feb. 4, 1645. He found refuge, as private chaplain, with Richard Vaughan, 2nd earl of Carbery (1600–1686), whose hospitable mansion, Golden Grove, Carmarthenshire, is immortalized in the title of Taylor's great manual of devotion, and whose first wife was a constant friend of Taylor. The second Lady Carbery was the original of the "Lady" in Milton's *Comus*. Mrs. Taylor had died early in 1651. His second wife was Joanna Bridges, said on very doubtful authority to have been a natural daughter of Charles I. She owned a good estate, though probably impoverished by Parliamentarian exactions.

From time to time Jeremy Taylor appears in London in the company of his friend Evelyn, in whose diary and correspondence his name repeatedly occurs. He was three times imprisoned: in 1654–5 for an injudicious preface to his *Golden Grove;* again in Chepstow castle, from May to October 1655, on what charge does not appear; and a third time in the Tower in 1657–8, on account of the indiscretion of his publisher, Richard Royston, who had adorned his "Collection of Offices" with a print representing Christ in the attitude of prayer.

Much of his best work was produced at Golden Grove. In 1646

appeared his famous plea for toleration, Θεολογία'Εκλεκτική, *A Discourse of the Liberty of Prophesying.* In 1649 he published the complete edition of his *Apology for authorized and set forms of Liturgy against the Pretence of the Spirit,* as well as his *Great Exemplar . . . a History of . . . Jesus Christ,* a book which was inspired, its author tells us, by his earlier intercourse with the earl of Northampton Then followed in rapid succession the *Twenty-seven Sermons* (1651), "for the summer half-year," and the *Twenty-five* (1653), "for the winter half-year," *The Rule and Exercises of Holy Living* (1650), *The Rule and Exercises of Holy Dying* (1651), a controversial treatise on *The Real Presence . . .* (1654), the *Golden Grove; or a Manuall of daily prayers and letanies . . .* (1655), and the *Unum Necessarium* (1655), which brought upon him the accusation of Pelagianism. In reply to a request from Katherine Phillips (the "matchless Orinda"), he wrote his *Discourse of the Nature, Offices and Measures of Friendship* (1657). His *Ductor Dubitantium, or the Rule of Conscience . . .* (1660) was intended to be a standard manual of casuistry and ethics for Christian people.

He probably left Wales in 1657, and his immediate connection with Golden Grove seems to have ceased two years earlier. In 1658, through the kind offices of his friend John Evelyn, Taylor was offered a lectureship in Lisburn, Ireland, by Edward Conway, second Viscount Conway. At first he declined a post in which the duty was to be shared with a Presbyterian, or, as he expressed it, "where a Presbyterian and myself shall be like Castor and Pollux, the one up and the other down," and to which also a very meagre salary was attached. He was, however, induced to take it, and found in his patron's mansion at Portmore, on Lough Neagh, a congenial retreat.

At the Restoration, instead of being recalled to England, as he probably expected and certainly desired, he was appointed to the see of Down and Connor, to which was shortly added the small adjacent diocese of Dromore. He was also made a member of the Irish privy council and vice-chancellor of the university of Dublin. None of these honours were sinecures. Of the university he writes, "I found all things in a perfect disorder . . . a heap of men and boys, but no body of a college, no one member, either fellow or scholar, having any legal title to his place, but thrust in by tyranny or chance." Accordingly he set himself vigorously to the task of framing and enforcing regulations for the admission and conduct of members of the university, and also of establishing lectureships. His episcopal labours were still more arduous. There were, at the date of the Restoration, about seventy Presbyterian ministers in the north of Ireland, and most of these were from the west of Scotland, and hated episcopacy. The new bishop had nothing to offer the Presbyterian clergy but the bare alternative—submission to episcopal ordination and jurisdiction or deprivation. Consequently, in his first visitation, he declared thirty-six churches vacant; and of these forcible possession was taken by his orders. At the same time many of the gentry were won by his undoubted sincerity and devotedness as well as by his eloquence. With the Roman Catholic population he had no success. At the instance of the Irish bishops Taylor undertook his last great work, the *Dissuasive from Popery* (in two parts, 1664 and 1667), but, as he himself seemed partly conscious, he might have more effectually gained his end by adopting the methods of Ussher and Bedell, and inducing his clergy to acquire the Irish tongue. He died at Lisburn on Aug 13, 1667 and was buried in the cathedral of Dromore.

Of a genuine poetic temperament, fervid and mobile in feeling, and of a prolific fancy, Taylor had also the sense and wit that come of varied contact with men. All his gifts were made available for influencing other men by his easy command of a style rarely matched in dignity and colour. With all the majesty and stately elaboration and musical rhythm of Milton's finest prose, Taylor's style is relieved and brightened by an astonishing variety of felicitous illustrations, ranging from the most homely and terse to the most dignified and elaborate.

The whole works of . . . Jeremy Taylor with a life of the author and a critical examination of his writings was published by Bishop Reginald Heber in 1822, reissued after careful revision by Charles Page Eden (1847–54). His most popular works, *The Liberty of Prophesying, Holy Living,* and *Holy Dying* have been often reprinted. *The Poems and Verse-translations of Jeremy Taylor* were edited by Dr. A. B. Grosart in vol. i. of the *Miscellanies of the Fuller Worthies Library* (1870). The first biographer of Jeremy Taylor was his friend and successor, George Rust, who preached a funeral sermon (in 1668) which remains a valuable document. His life has been written by John Wheeldon (1793), H. K. Bonney (1815), T. S. Hughes (1831), R. H. Willmott (1847), George L. Duyckinck (New York, 1860) and by Edmund Gosse (1904) in the "English Men of Letters" series The chief authority is still Eden's revision of Bishop Heber's memoir, which includes much valuable correspondence. S. T. Coleridge was a diligent student and a warm admirer of Jeremy Taylor, whom he regarded as one of the great masters of English style. A series of comments by Coleridge are collected in his *Literary Remains* (1838, vol. iii, pp. 203–390).

TAYLOR, JOHN (1580–1653), English pamphleteer, commonly called the "Water-Poet," was born at Gloucester on Aug. 24, 1580. After fulfilling his apprenticeship to a waterman, he served (1596) in Essex's fleet, and was present at Flores in 1597 and at the siege of Cadiz. On his return to England he became a Thames waterman, and was at one time collector of the perquisites exacted by the lieutenant of the Tower. He was an expert in the art of self-advertisement, and achieved notoriety by a series of eccentric journeys With a companion as feather-brained as himself he journeyed from London to Queenborough in a paper boat, with two stockfish tied to canes for oars *The Pennyles Pilgrimage, or the Moneylesse Perambulation of John Taylor . . . how he travailed on foot from London to Edenborough in Scotland . . .* 1618, contains the account of a journey perhaps suggested by Ben Jonson's celebrated undertaking, though Taylor emphatically denies any intention of burlesque He went as far as Aberdeen. At Leith he met Jonson, who good-naturedly gave him 22 shillings to drink his health in England Other travels undertaken for a wager were a journey to Prague, where he is said to have been entertained (1620) by the queen of Bohemia, and those described respectively in *A very merry, wherry ferry voyage, or Yorke for my money,* and *A New Discovery by sea with a Wherry from London to Salisbury* (1623). At the outbreak of the civil war Taylor began to keep a public-house at Oxford, but when the Royalists surrendered the city he returned to London, where he set up a similar business at the sign of "The Crown" in Phoenix Alley, Long Acre. He was buried in the churchyard of St Martin's-in-the-Fields on Dec 5, 1653.

Sixty-three of Taylor's "works" appeared in one volume in 1630 This was reprinted by the Spenser Society in 1868–69, being followed by other tracts not included in the collection (1870–78) Some of his more amusing productions were edited (1872) by Charles Hindley as *The Works of John Taylor* They provide some very entertaining reading Mr Hindley edited other tracts of Taylor's in his *Miscellanea Antiqua Anglicana* (1873).

TAYLOR, JOSEPH (*c.* 1586–1652), English actor, is mentioned in the folio Shakespeare of 1623 as one of the 26 who took principal parts in all of these plays. He was with the duke of York's company in 1610, but involved himself in a lawsuit with John Hemings by leaving them to join the Lady Elizabeth's in the next year. He appeared in the actor list of the latter company in *The Honest Man's Fortune* (1613) and *The Coxcomb* (1613). From 1616 he was one of the prince's company, but left them to join the king's men in 1619. He remained with them until he retired, playing several of Burbage's parts, including Ferdinand in *The Duchess of Malfi,* and Hamlet There is a legend that he was trained by Shakespeare to play Hamlet. In many of Beaumont and Fletcher's plays he had a leading role, and he is one of the ten actors who signed the dedication of the first folio of these dramatists (1647). He led the king's men, with Lowin, after Hemings and Condell, and in 1630, after Hemings's death, obtained two shares in the Globe, and one in the Blackfriars theatres. In 1639 he was appointed yeoman of the revels. He died at Richmond, where he was buried on Nov. 4, 1652.

TAYLOR, ROWLAND (d. 1555), English Protestant martyr, was born at Rothbury, Northumberland; he took minor orders at Norwich in 1528 and graduated LL.B. at Cambridge in 1530 and LL.D. in 1534. Adopting reformed views he was made chaplain by Cranmer in 1540 and presented to the living of Hadleigh, Suffolk, in 1544 He was further preferred to a canonry of

Rochester (1547) and the archdeaconry of Exeter (1552). Apparently he advocated the cause of Lady Jane Grey, for on the 25th of July 1553, only six days after Mary's proclamation as queen, he was committed to the custody of the sheriff of Essex. He was released not long afterwards, and with the support of his parishioners offered strenuous resistance to the restoration of the Mass. He was consequently imprisoned in the King's Bench prison on March 26, 1554. He was sentenced on Jan. 22, 1555, and burnt on the 9th at Aldham Common near Hadleigh.

See Thomas Quinton Stow's *Memoirs of Rowland Taylor* (1833); *Dict. of Nat. Biogr.* lv. 463–4, and authorities here cited.

TAYLOR, TOM (1817–1880), English dramatist and editor of *Punch*, was born at Bishop Wearmouth, on Oct. 19, 1817. He was a fellow (1837) of Trinity college, Cambridge, and for two years professor of English literature at University college, London. He was called to the bar (Middle Temple) in Nov. 1846, and went on the northern circuit until, in 1850, he became assistant secretary of the Board of Health. On the reconstruction of the board in 1854 he was made secretary, and on its abolition his services were transferred to a department of the Home Office. He retired on a pension in 1876. Four burlesques of Tom Taylor's were produced at the Lyceum in 1844. He made his first hit with *To Parents and Guardians* (Lyceum, 1845). He also wrote some burlesques in conjunction with Albert Smith and Charles Kenny, and collaborated with Charles Reade in *Masks and Faces* (1852). Before the close of his life his dramatic pieces numbered over 100, amongst the best known of which are *Our American Cousin* (1858), produced by Laura Keene in New York, in which Sothern created the part of Lord Dundreary; *Still Waters Run Deep* (1855); *Victims* (1857); and the *Ticket of Leave Man* (1863).

Taylor wrote leaders for the *Morning Chronicle* and the *Daily News*. He was on the staff of *Punch* until 1874, when he succeeded Shirley Brooks as editor. He was a good amateur actor, an artist, and an art critic of *The Times*. He died at Lavender Sweep, Wandsworth, on July 12, 1880.

TAYLOR, ZACHARY (1784–1850), twelfth president of the United States, was born in Orange county, Virginia, Sept. 24, 1784. Within the year his father, Richard Taylor, an officer in the Revolutionary War, made a new home for his family in Kentucky where Washington appointed him collector of the port of Louisville, then on the border and Spaniards and Indians were still a menace. In this environment Zachary Taylor spent his youth, and gained what little schooling he was to enjoy from Elisha Ayres, a New England tutor, who was employed by the elder Taylor to ground his numerous family in the rudiments. In 1806 he volunteered during the difficulties caused by Aaron Burr's southwestern schemes and saw brief service. Two years later through the instrumentality of his relative, James Madison, and others, Zachary Taylor was given a commission by Jefferson as first lieutenant in the seventh infantry, the beginning of his military career of 40 years duration.

As captain and major he served through Harrison's Indian campaign and the War of 1812 in the northwest territory and at the close of the war temporarily left the army because reduction to peace-time strength had lowered his rank. However in 1816 President Madison reappointed him to his old rank and there ensued twenty years of garrison life at various posts, varied in 1832 by an expedition against Black Hawk. The outbreak of the Seminole War in 1837 found him an infantry colonel in the Northwest and soon orders came for him to take his command to the Everglades. In this bewildering warfare he spent three years gaining promotion to the rank of brigadier-general by brevet for his service in the battle of Kissimmee on Lake Okeechobee and receiving command of operations. He was able to make little impression against these Indian foes and in 1840 asked to be relieved. He was given command of the first department with headquarters in Louisiana, which enabled him to acquire a plantation at Baton Rouge and establish a home where he spent many intervals between tours of inspection. When Texas was acquired in 1845 it fell to him to protect the new possession and he was ordered by the War department to occupy the borders of Texas; by the spring of 1846 he had moved down to the mouth of the Rio Grande with a force of over 3,000 men and established Ft. Brown. The Mexican army was concentrated across the river with orders to drive the Americans out of the contested area; the result was a skirmish on the American side of the river, April 24, and war was immediately declared. Taylor found himself in a precarious situation because of the exposed position of his base of supplies at Pt. Isabel and while manoeuvring to protect this base he fought the Mexican army winning two victories at Palo Alto (*q.v.*) and Resaca de la Palma (*q.v.*) on May 8 and 9, 1846. These victories sent the Mexicans across the river to Matamoras. Taylor was unprepared to follow up his advantage so when he finally crossed the river and occupied Matamoras (May 18), the enemy had gone. The news of these victories was received with great appreciation throughout the country and various persons including Whig editors and politicians began to see the possibilities of a presidential candidate in the victorious general. Thereupon, because Gen. Winfield Scott, commander of the army, was so slow in preparing to take active charge, President Polk placed Taylor in command of the invasion of Mexico and appointed him major-general at first by brevet and then in full rank. After slow preparations at Matamoras he moved in August to the head of navigation on the Rio Grande where he established a depot at Camargo and then set out for his first objective, Monterey. September 21–24 witnessed a series of vigorous skirmishes, heroic assaults and grave errors. Taylor with little knowledge of military science or the use of artillery resolved to take the town by bayonet assault which caused considerable slaughter of his own men. But the fighting was so effective that on the third day the Mexicans agreed to surrender if they be permitted to retreat and be granted an eight weeks' armistice, subject to the approval of the respective governments. Taylor accepted these terms, and "Old Rough and Ready," was acclaimed once more throughout the land.

Vexations followed. The War department began to make suggestions as to the movements of his subordinates and the administration disapproved the armistice. These matters incensed Taylor who was becoming convinced that Polk and Marcy were trying to discredit him because of their political differences. He vetoed the plans for his subordinates, wrote a letter to Gen. Gaines criticizing the administration which later found its way into the press and brought down Marcy's rebuke, and moved on to Saltillo which he occupied Nov. 16, deciding to take possession of the territory between that point and the sea-coast where Tampico had fallen into the hands of the navy. While carrying out these plans he received a letter from Gen. Scott informing him that Scott was to lead an expedition into Mexico and, without divulging the plan, indicated that he would need most of Taylor's troops, requesting a meeting to perfect the details. Taylor upon receiving this note decided that instead of meeting Scott he would go as far away as he could, and accordingly went to Victoria which Quitman had lately occupied. When Scott learned of this move, he contented himself with ordering the greater part of Taylor's troops to the coast to embark for Vera Cruz while with the remainder Taylor was to defend the occupied territory in northern Mexico. Taylor protested to the War department and informed Senator Crittenden that he was a receptive candidate for the presidency. Reluctantly he led the remnant of troops left him by Scott back to Monterey, but instead of remaining there moved southward where word came that Santa Anna with 20,000 troops was advancing upon Taylor who had only a quarter of that number. The armies met at Buena Vista (*q.v.*), Feb. 22, 1847, and in spite of his lack of skill, his army inspired by his presence snatched a victory from defeat and the north of Mexico was saved. At home, the feeling was general that Taylor had been stripped of his troops by a jealous administration and left to perform the impossible. This ended his military activity but his political availability increased.

Shrewd politicians had become increasingly convinced of his potentialities as a candidate. The Whig party was especially in need of a strong candidate to retrieve the defeat of 1844. Very early in the war, Thurlow Weed of New York began pushing him and popular enthusiasm made his task easier. His correspondence was skillfully handled; he was reluctant, he maintained, and with truth, to be a seeker for the office; he had never voted and though

a Whig in sympathy was not an avowed partisan. As a slaveholder also he was certain to gain votes in the South where there was a good deal of suspicion that northern influences dominated the Whig managers. These advantages were sufficient to ensure success and in the Whig convention on the fourth ballot, Taylor won the nomination from Clay, Webster and Scott. An opportune split in the Democratic party ensured his victory and on March 5, 1849 he was inaugurated.

Few presidents have had less knowledge of what was expected of them. The new executive expected to be a non-partisan president, leaving to Congress all legislative matters and confining himself to executing the laws. With Col. Bliss, his son-in-law, to phrase his thoughts, he, at first, was more or less influenced in his policies by Vice-Pres Fillmore, but it was not long before the superior astuteness of Sen. Seward, Fillmore's rival in New York State, accomplished results The new president became convinced that it was his duty to build up the Whig party by means of clever patronage, and deserving Whigs began to come into their own.

With these preliminary lessons learned, Taylor found his most perplexing problem to be the status of the newly acquired territory. As a soldier he was anxious to see stable government established. In order to hasten this he authorized Congressman King of Georgia to go to California and urge an application for statehood. When Congress met, Dec. 1849, the President had the pleasure of reporting that California was ready to become a State and that New Mexico would be soon. He recommended the admission of California and hoped that the slave issue would not be injected into the situation. When Southern representatives objected because California had prohibited slavery, he resented their protests. He declared himself willing to accept any law providing for admission, passed by Congress and warned Southern leaders that he would take the field if necessary to carry out such a law and hang any who resisted. His attitude was the natural reaction of a military executive to those opposed to the regular process of law and order Consequently he was not in favour of conciliating those opposed and referred contemptuously to the Compromise measures of 1850 as the "Omnibus Bill." In other respects his administration was not proving a sinecure; charges were made against his secretary of war, Crawford, to the effect that he had used his official position to pursue a claim successfully before the secretary of the treasury by which he benefited financially. This charge involving the secretaries of war and the treasury as well as the attorney-general, deeply mortified Taylor who prided himself on scrupulous honesty and he determined to reorganize his cabinet. Then came the fatal July 4, 1850, when exposure to the heat and injudicious eating combined with worry, aggravated an attack of typhus fever, which caused his death five days later

A combination of honesty, simplicity, determination and common-sense had brought him successfully through a variety of difficult situations and by a strange turn of the wheel carried him to the White House.

Taylor had six children, three of whom survived him. One daughter, Sarah Knox Taylor, gained his reluctant consent to marry a young subaltern, Jefferson Davis, in 1835, surviving the marriage but three months His only son, Richard Taylor (1826–1879) graduated from Yale in 1845 and after a short service in his father's camp, became a sugar-planter and politician in Louisiana. At the outbreak of the Civil War he entered the Confederate army and served in various capacities, finally commanding an army which surrendered in May 1865

TAYLOR, an anthracite-mining borough of Lackawanna county, Pennsylvania, U S A., on the Lackawanna river. Pop. (1920) 9,876 (29% foreign-born white).

TAYLOR, a city of Williamson county, Texas, U S A, 35 m. N E. of Austin, on the Missouri-Kansas-Texas and the Missouri Pacific railways. Pop. (1920) 5,965 (23% negroes) estimated locally at 7,500 in 1928. The city gins 40,000 bales of cotton in a normal year; has three chick hatcheries, railway shops and other manufacturing industries. Natural gas was turned into the city mains on Sept. 1, 1928. Taylor was founded in 1876, incorporated in 1882 and has had a commission-manager form of government since 1910. It was named after General Zachary Taylor.

TAYLOR'S THEOREM, the statement of a formula discovered by Brook Taylor (*q.v.*) in 1712, and published three years later in his *Methodus incrementorum directa et inversa* (1715). The formula provides for the expansion of a function of $x+h$ as follows:—

$$f(x+h) = f(x)+hf'(x)+\frac{h^2}{2!}f''(x)+ \dots$$

A related formula, published by the Scottish mathematician Colin Maclaurin (1698–1746) in 1742 and bearing his name, gives the expansion of a function of x in the following manner:

$$f(x) = f(o)+xf'(o)+\frac{x^2}{2!}f''(o)+ \dots$$

It often happens that the value of such expressions as sin$x$, tan$x$, log$x$, and e^x is required to a higher degree of accuracy than is given by available tables; for example, the value of tan 1·2 radians. In this case tan$x$ can be expanded by such formulae and its value can be found by substituting 1·2 for x. (*See* SERIES) (D. E. S.)

TAYLORVILLE, a city of central Illinois, U.S.A., on the Sangamon river, 26 m. S.E. of Springfield; the county seat of Christian county. It is served by the Baltimore and Ohio, the Chicago and Illinois Midland and the Wabash railways. Pop 5,806 in 1920 (92% native white); estimated locally at over 11,000 in 1928. There are four large coal mines near by.

TCHEREPNIN, NICOLAI (1873–), Russian composer, was born at St. Petersburg (Leningrad) on May 15, 1873. He first studied law, and it was not until 1895 that he decided to take up music. He then entered the conservatoire, where he took composition with Rimsky-Korsakov. In 1901 he was appointed conductor of the Belaeiev orchestral concerts in St. Petersburg and from 1908–14 he conducted for Diaghilev in Paris and elsewhere. In 1914 he returned to Russia and from 1918–21 was director of the conservatorium at Tiflis, after which he settled in Paris. His best known works are the ballets *Le pavillon d'Armide* and *Narcissus. A Russian Fairy Tale* was produced by Madame Pavlova's company. In 1925 he wrote *The Romance of a Mummy.* Other works are: *Narcissus and Echo* and *The Enchanted Garden* (symphonic poems), two masses, and a string quartet.

His son ALEXANDER TCHEREPNIN, born in St. Petersburg in 1899, is a well-known pianist and composer, his principal works being: *The Frescoes of Ajanta* (ballet, produced by Pavlova, 1923), a piano concerto and sonatas, a concerto for flute and violin with small orchestra op. 33 (1925), and a string quartet, op. 36, entitled "Liebesopfer der heiligen Therese vom Kinde Jesu."

TCHERNAIEV, MIKHAIL GREGORJOVICH (1828–1898), Russian general, a member of a noble family, was born on Oct. 24, 1828. Educated at the Nicholas Staff college, he entered the army in 1847, and distinguished himself in the Crimean war and in the Caucasus. After serving as divisional chief of the staff in Poland, he went to Orenburg in 1858 as assistant to the commander of the line of the Syr-Darya, and the following year commanded an expedition to support the Kirghiz tribes on the borders of the Sea of Aral against the Khivans. He did duty on the staff of the army of the Caucasus for a time, and returned to Orenburg as chief of the staff. In 1864, having reached the rank of major-general, he made his famous march with 1,000 men across the steppes of Turkestan to Chimkent in Khokand, to meet another Russian column from Semipalatinsk, in Siberia, in conjunction with which he successfully stormed Chimkent, and then unsuccessfully attacked Tashkent, 80 miles farther south. Wintering at Chimkent, he captured Tashkent the following year. This was contrary to his instructions, and although he was received in St. Petersburg with enthusiasm, and presented with a sword of honour by the emperor, he was not again employed in the military service, and retired from it in July 1874. He bought, and edited with great success, the *Russkiy Mir* in Slavonic in-

terests, devoting himself to the Panslavic idea. In the summer of 1876 he was appointed commander-in-chief of the Serbian army, but on entering Turkey was driven back by Osman Pasha, who followed him into Serbia defeating him at Zayechar and Yavor in July, and the campaign in Serbia proved disastrous. He rashly proclaimed Milan king of Serbia in September, and in October Aleksinats and Deligrad were in the hands of the Turks, and the road open to Belgrade. An armistice was concluded, and Tchernaiev resigned his command. In 1877 he visited Austria in connection with his propaganda, but was expelled, and lived for a time in France. In 1879 he organized a Bulgarian rising, but was arrested at Adrianople and sent back to Russia. He succeeded Kaufmann (*q.v.*) as governor of Turkestan in 1882, but his aggressive policy led to his recall two years later, when he was appointed a member of the council of war at St. Petersburg. In 1886 his opposition to the Central Asian Military railway caused him to lose his seat in the council. He died on the 16th of August 1898, at his country seat in the province of Mogilev.

TCHERNOV, VICTOR (VICTOR OLIENIN), co-founder and for many years the principal leader of the Russian socialist revolutionary party, was first associated with its predecessor, the "people's right" group. Until 1914 he occupied a centrist position in the party, but during the world war he differed from other leading members by reason of his anti-war attitude. He participated in the Zimmerwald conference of 1915. After the February 1917 revolution he held the position of minister for agriculture in the coalition government of May 1917, but soon withdrew owing to the opposition of the other coalition parties to his radical agrarian proposals. During 1917 he was unable to control his party or to get its various groups to adopt a single programme, and his position as leader of the "peasants' party" was largely stultified in consequence. Still, he was elected President of the All-Russian Constituent Assembly which opened on January 18th, 1918 and, after a single day's session, was dispersed by the Bolshevist Government. After this, Tchernov took an active and leading part in the anti-Bolshevist movement on the Volga. After the end of civil war, he readapted his centrist attitude and, as the editor of *Revolutionary Russia*, he continued his activity as one of the leaders of the Social-Revolutionary Party. He escaped from Russia in 1918 and has since been living in exile.

TCHIHATCHÓV, PIERRE ALEXANDROVICH (1812–1890), Russian naturalist and geologist, was born at Gatchina near St. Petersburg, in 1812. He entered the diplomatic service and was (1842–44) attached to the embassy at Constantinople; whence he visited Asia Minor, Syria and Egypt. In 1844, he was charged with a scientific mission to the Altai mountains. He died at Florence on the 13th of October 1890 (N.S.).

His publications include: *Voyage scientifique dans l'Altai oriental et les parties adjacentes de la frontière de Chine* (with atlas, 1845); *Asie Mineure; description physique, statistique et archéologique de cette contrée* (4 vols. with 3 atlases, 1853–69); *Le Bosphore et Constantinople* (1864, another ed. 1877); *Considérations géologiques sur les Iles Océaniques* (1878); and *Espagne, Algérie et Tunisie* (1880).

TCZEW (German DIRSCHAU), a town of Poland, in the province of Pomorze, on the left bank of the Vistula, 20 m. S. from Danzig, at the junction of the main railway lines Danzig-Bydgoszcz and Berlin-Königsberg. The river is here crossed by two fine iron bridges. The chief industries are railway workshops and the manufacture of sugar, cement and agricultural implements. In 1923 it was found impossible to deal with the whole timber export from Poland at Danzig alone. Part of the goods, therefore, were unloaded at Tczew. The project is therefore being considered of connecting the town with the sea by a canal. If this is realized, Poland will have two ports to supplement the city of Danzig.

TEA, the name given to the leaves of the tea bush (Chinese *cha,* Amoy dialect *té*), prepared as a beverage. The term is by analogy also used for an infusion or decoction of other leaves, *e.g.,* camomile tea; and similarly for the afternoon meal at which tea is served.

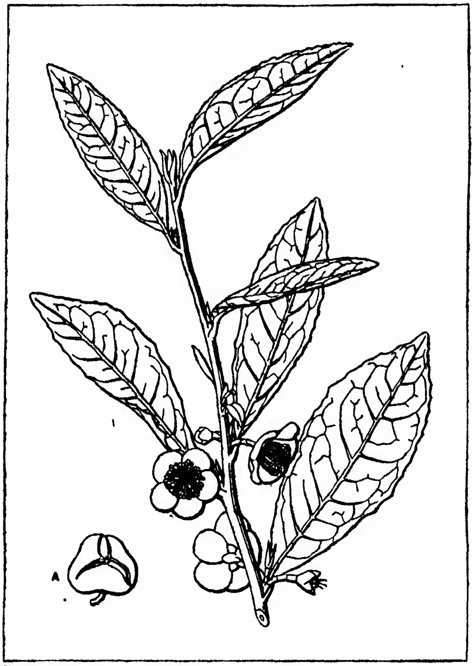
The Discovery of Tea.—The early history of tea as a beverage is mainly traditional. According to Chinese legend, the virtues of tea were discovered by the Emperor Shên-nung, 2737 B.C., to whom all agricultural and medicinal knowledge is traced. A tradition exists in China that a knowledge of tea travelled eastward to and in China, having been introduced A.D. 543 by Bodhidharma, an ascetic who came from India on a missionary expedition. Bodhidharma vowed that he would contemplate the virtues of Buddha through 9 unsleeping years. At the end of 3 years he slept and in his anger at his weakness he cut off his eyelids and threw them on the ground beside him. After a further five years of contemplation he again felt drowsy and plucking some leaves from a nearby shrub he found stimulation to complete his 9 years. This shrub was called *cha,* or tea. The use of tea in China in the middle of the 9th century is known from Arab sources (Reinaud, *Relation des Voyages,* 1845, p. 40). From China a knowledge of tea was carried into Japan, and there, according to historical records, the cultivation was established during the 9th century.

The earliest mention of tea by an Englishman is probably that contained in a letter from Mr. Wickham, an agent of the East India Company, written from Firando in Japan, on the 27th June 1615, to Mr. Eaton, another officer of the company, resident at Macao, and asking for "a pot of the best sort of *chaw.*" It was not till the middle of the century that the English began to use tea, and they also received their supplies from Java till in 1686 they were driven out of the island by the Dutch. At first the price of tea in England ranged from £6 to £10 per lb. In the *Mercurius Politicus,* No. 435, of September 1658, the following advertisement occurs:—"That excellent and by all Physitians approved China Drink called by the Chineans *Tcha,* by other nations *Tay, alias Tee,* is sold at the Sultaness Head, a cophee-house in Sweetings Rents, by the Royal Exchange, London." Thomas Garway, the first English tea dealer, and founder of the well-known coffee-house, "Garraway's," in a curious broadsheet, *An Exact Description of the Growth, Quality and Virtues of the Leaf Tea,* issued in 1659 or 1660, writes, "in respect of its scarceness and dearness, it hath been only used as a regalia in high treatments and entertainments, and presents made thereof to princes and grandees." In that year he purchased a quantity of the rare and much-prized commodity, and offered it to the public, in the leaf, at fixed prices varying from 15s. to 50s. the lb., according to quality, and also in the infusion, "made according to the directions of the most knowing merchants and travellers into those eastern countries." Pepys's often-quoted mention of the fact that on September 25, 1666, "I did send for a cup of tee, a China drink of which I never had drunk before," proves the novelty of tea in England at that date.

Until the Revolution no duty was laid on tea other than that levied on the infusion as sold in the coffee-houses. By 1 William and Mary, c. 6, a duty of 5s. per lb. and 5 per cent. on the value was imposed. For several years the quantities imported were very small, and consisted exclusively of the finer sorts. The first direct purchase in China was made at Amoy, the teas previously obtained by the Company's factors having been purchased in Madras and Surat, whither it was brought by Chinese junks after the expulsion of the British from Java. During the closing years of the century the amount brought over seems to have been, on the average, about 20,000 lb. a year. The average price of tea at this period was 16s. per pound.

As the 18th century progressed the use of tea in England rapidly increased, and by the close of the century the rate of consumption exceeded an average of 2 lb. per person per annum, a rate in excess of that of to-day of all people except those of Mongol and Anglo-Saxon origin. The business being a monopoly of the East India Company, and a very profitable one, the company at an early stage of its development endeavoured to ascertain whether tea could not be grown within its own dominions. Difficulties with China doubtless showed the advisability of having an independent source of supply. In 1788 Sir Joseph Banks, at the request of the directors, drew up a memoir on the cultivation of economic plants in Bengal, in which he gave special prominence to tea, pointing out the regions most favourable for its cultivation. About the year 1820 David Scott, the first com-

missioner of Assam, sent to Calcutta from Kuch Behar and Rangpur—the very districts indicated by Sir Joseph Banks as favourable for tea-growing—certain leaves, with a statement that they were said to belong to the wild tea-plant. But it was not till 1834 that Captain Francis Jenkins proved the fact of the genuine tea-plant being a native of British territories in Upper Assam In the meantime a committee had been formed by Lord William



FLOWERING SHOOT OF THE TEA PLANT (CAMELLIA THEA, LINN.), AND (A) SEED POD

Bentinck, the governor-general, for the introduction of tea culture into India. Evidence of the abundant existence of the indigenous tea-tree was obtained; and the directors of the East India Company resolved to institute an experimental establishment in Assam for cultivating and manufacturing tea.

In 1834 the monopoly of the East India Company was abolished and an era of rapid progress in the new industry began. In 1836 there was sent to London 1 lb. of tea made from indigenous leaves; in 1840 there were grown, and offered at public auction in Calcutta early the following year, 95 packages, "the produce of the Government tea plantation in Assam." This auction is most interesting as being the first of British-grown tea, and it included about 6,000 lb. In Jan. 1840 the Assam Company was formed to take over the early tea garden of the East India Company.

The Dutch were rather earlier than the English in attempting to establish tea growing in their eastern possessions. A beginning was made in Java in 1826, but probably because of the even more marked influence of Chinese methods and Chinese plant, the progress was slow and the results indifferent. Later, however, by the introduction of fine Assam seed and the adoption of methods similar to those in use in India, great success was achieved.

Somewhere about 1860 the practical commercial growing of tea was introduced into the island of Formosa. The methods of cultivation and manufacture followed there differ in many ways from those of the other large producing countries, but the industry has been fairly successful throughout its history.

Attempts were repeatedly made to introduce tea culture in Ceylon, under both Dutch and British authority. No permanent success was attained till about 1876, when the disastrous effects of the coffee-leaf disease forced planters to give serious attention to tea. Since that period the tea industry has developed with marvellous rapidity, and now takes first rank in the commerce of the island.

Since the beginning of the 20th century tea-growing has been established in certain districts in Africa and also in Sumatra, where in 1926 the production exceeded 138,000,000 pounds (X.)

Botany of Tea.—The tea bush or tree is a member of the family Theaceae (formerly included under Ternstroemiaceae) and closely related to the well-known ornamental shrub the Camellia. As cultivated in China it is an evergreen shrub growing to a height of from 3 to 5 ft. The stem has numerous and very leafy branches; the leaves are alternate, leathery, elliptical, obtusely serrated, strongly veined and placed on short, channelled foot-stalks. The under side of the young leaf is densely covered with fine hairs, which disappear with increasing age. A characteristic feature of the cellular structure of the tea-leaf is the presence of large, branching, thick-walled, smooth cells (idioblasts), which, although they occur in other leaves, are not found in such as are likely to be confounded with or substituted for tea The flowers are white, axillary and slightly fragrant, often two or three together on separate pedicels The fruit is a woody capsule containing one to three or more nearly spherical seeds about the size of a hazel nut. The plant was originally described by Linnaeus as one species, *Thea sinensis.* Later, Linnaeus recognised two species, as previously described by Hill, viz, *Thea viridis* and *Thea Bohea,* and it was erroneously assumed that the latter was the source of black tea, while *Thea viridis* was held to yield green tea. In 1843, however, Robert Fortune found that black and green tea were produced from the leaves of the same kind of plant by varying the manufacturing process.

For botanical reasons the tea plant is now referred to the genus *Camellia* and is usually described as *Camellia Thea Linn.*, though some authorities, on grounds of priority, would prefer the name *Camellia theifera* (Griffith) Dyer.

Sir George Watt (*Jour. Roy Hort Soc.*, vol xxxii, 1907) described the recognised varieties and races of *Camellia Thea* (with special reference to those of India) and placed them in the following classification:

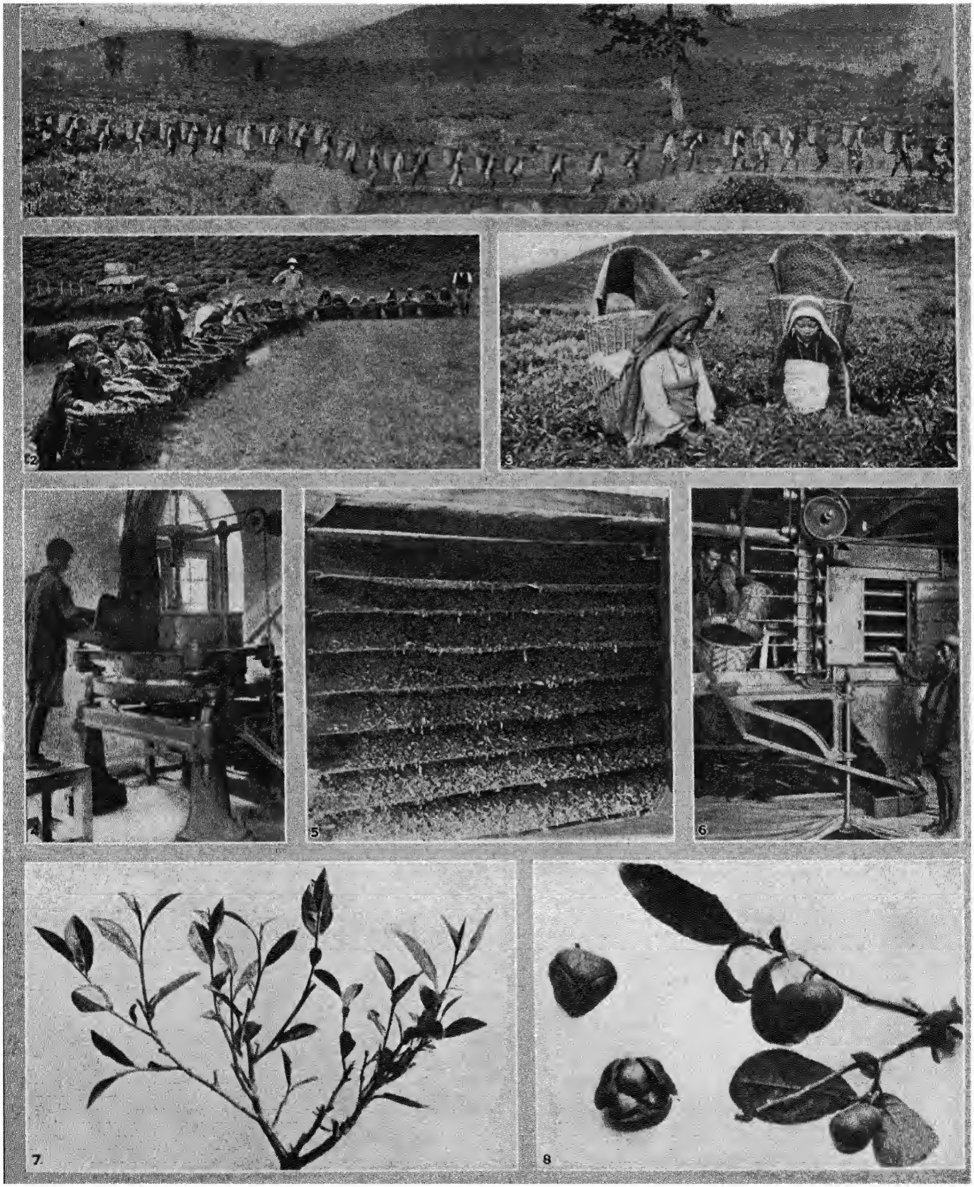
A. Variety *viridis* —races
1. Assam Indigenous.
2. Lushai.
3. Naga Hills.
4. Manipur.
5. Burma and Shan.
6. Yunan and Chinese.

B. „ *Bohea.* (China, Japan, Formosa, India.)

C. „ *stricta.* (India, China)

D. „ *lasiocalyx.* (Malacca, Penang.)

Teas of Commerce.—Of the foregoing, the teas of commerce are derived almost entirely from the varieties *viridis* and *Bohea* The Assam Indigenous, in its two sub-races of Singlo and Bazelona, and the Manipur have, with various intermixtures and crossings, been used to cover the greatest areas of all the more modern planting in India, Ceylon and the Dutch East Indies (Java and Sumatra). The large size of leaf when fully developed (4 to 9 in. long and 2 to $3\frac{1}{2}$ in. broad) has made them in demand because of the heavy yields. From the variety *Bohea,* or from hybrids of descent from it, came the China teas and the earlier plantings in India grown from imported China stock. The leaves of this variety are generally about half the size of those of the Assam Indigenous and Manipur sorts. The bush is in every way smaller than the Assam types. The latter is a tree attaining in its natural conditions, or where allowed to grow unpruned as in a seed garden, a height of from 30 to 40 feet. Full information regarding the botanical classification of the plants yielding China teas is not yet available, but it would seem that in the main they fall under the varieties *viridis* and *Bokea.*



BY COURTESY OF THE INDIAN TEA ASSOCIATION, LONDON

CULTIVATION OF TEA

1. Chinese coolies transporting tea from the fields in baskets. 2. Young coolies waiting in line to have their baskets of tea weighed. 3. Plucking tea leaves in the field. Both hands are used. 4. Rolling the tea. A twist is imparted to the leaves by the top and bottom tables which revolve in opposite directions. 5. Withering the tea leaves. This is the most important of all operations in tea manufacture. About 18 hours are needed to complete the process. 6. Firing the tea in a "Venetian" drier. A temperature of 220° F. is maintained. 7. A tea shoot. Only the bud spike and the first two leaves are plucked. 8. Tea seeds

Much controversy has taken place as to the original home of the tea-plant. The modern view is that the plant is probably indigenous to the whole monsoon region of Eastern Asia, notably the Assam-Yunan area.

Tea Planting.—The following account of the planting, harvesting and manufacture of tea may be taken as generally representative of the practice adopted in India, Ceylon, Java and Sumatra which, apart from China and Japan, are the chief tea-producing countries.

Climate and Soil.—For its successful cultivation as a crop plant tea requires a warm, sub-tropical climate and a moist, steaming atmosphere resulting from frequent, copious rains. It thrives best in rich, light, friable soils, containing stores of humus, well drained and of good depth. Undulating, well-watered tracts where the rain escapes freely, yet without washing away the soil, are the most valuable for tea gardens. Propagation is from seed obtained from special plants set apart for seed purposes. The young plants are raised in carefully prepared nurseries and, when about 6 or 8 inches high, are set out in the plantation at a distance of from 4 to 6 ft. each way. Much attention is paid to the cultivation of the soil and the weeding of the plantation.

The value of manures is now widely recognised by planters, and animal, chemical and "green" manures are used.

Pruning.—Pruning is a most important operation and is designed to produce a bush of convenient size for plucking and to increase leaf-production. Commonly, the plant when one or two years old is cut down to within less than a foot of the ground. The main stem thus removed is replaced by three or four lateral branches which, after growing for two years, are cut back at the second pruning and later themselves bear laterals. Subsequent prunings in India are usually carried out annually, or at longer intervals in Southern India and in Ceylon. Old bushes yielding poor crops are often "heavy pruned" by cutting down to within 12 or 15 inches from the ground.

Plucking.—A very small crop of leaf may be obtained in the second year after planting out; in the third year about 150 lb. of finished tea per acre per annum is obtained in the Indian plains; and by the sixth or eighth year the bushes should be in full bearing yielding from 400 lb. to 1,000 lb. of finished tea per acre annually. In India plucking is carried out every seven to ten days, there being 20 to 30 pluckings during the season. The first plucking or "tipping" is done when the new shoots are about 9 inches long and with not less than five or six leaves, excluding the apical bud and the scale-leaf at the base of the shoot.

This plucking removes the apical bud and the two youngest leaves and is carried out more for the purpose of inducing further "flushes" (young shoots) from the axils of the remaining leaves than of obtaining leaf. The flushes are taken every seven or ten days. In the best practice the tip of the shoot, including two leaves and the terminal bud, is the standard pluck; one leaf and the bud yields a finer tea, while a pluck of three or four (older) leaves gives a coarser tea. Late in the season a heavy "close pluck" of nearly all leaf growth is commonly taken to secure a heavy crop. The finest teas are produced at high elevations in Darjeeling (India) and Ceylon and in the plains of Assam.

Pests and Diseases.—Among insect enemies of the tea plant the so-called "mosquito" (*Helopeltis theivora*), a plant-bug, is the most serious, other important pests being "red spider" (a mite, *Tetranychus bioculatus*), pink mite (*Eriophyes* [*Phytopus*] *theae*), the misnamed "green fly" (a plant-bug, *Chlorita flavescens*) and "thrips" (*Physothrips setiventris,* the common thrips; and *Haplothrips tenuipennis,* the black thrips); a number of caterpillars and scale insects also cause damage. All these pests attack the leaves or young shoots. Among blights of vegetable origin the so-called "red-rust" of the leaves and shoots, caused by an alga (*Cephaleuros parasiticus*), is probably the most serious. The chief fungus diseases are "grey blight" (*Pestalozzia Theae*) and "blister blight" (*Exobasidium vexans*) which attack the leaves and shoots; while "pink disease" (*Corticium salmonicolor*), branch canker (*Nectria* sp.) and "die-back" are stem diseases; root diseases caused by fungi also occur.

Tea Manufacture.—In the making of a good quality tea much depends upon the character of the plant and the circumstances of its growth and cultivation, but satisfactory methods of manufacture in dealing with the plucked leaf are also essential. Formerly, the processes were carried out by hand methods, but in the most modern practice machinery is employed in practically every operation. In the manufacture of tea the most important feature is the regulation of the fermentation (oxidation) process. This fermentation is the cardinal feature in the making of black teas (which form by far the greater part of the teas entering commerce), but in preparing green teas the fermentation is prevented.

Black Tea.—The following are the stages in the manufacture of black tea:

(1) *Withering.* The plucked leaf is brought at once into the shady withering house and spread thinly in sterilised shallow trays made of hessian, bamboo or wire netting and arranged on racks; or, the leaf is commonly spread on clean withering floors. Withering is complete when the leaf has become soft and flaccid. The process usually occupies from 18 to 20 hours but must obviously depend upon varying conditions of temperature and moisture of the air. On this account special machines for withering the leaf under conditions which may be readily controlled are now being widely used. The immediate object of withering is to obtain the leaf in a physical condition suitable for the subsequent rolling, but during the process the oxidising enzyme (ferment) present in the leaf, which brings about the important changes in the later fermentation process, greatly increases in quantity, while other chemical changes also take place.

(2) *Rolling.* The withered leaf is fed into the "jackets" of rolling machines which operate by rubbing the leaf, under adjustable pressure, between two metal surfaces. The time occupied in the rolling varies from 15 to 60 minutes after which the rolled leaf is sifted and the older leaves treated again; irregular balls of leaf are broken up by revolving beaters fitted to the sieves. Rolling imparts to the tea it's characteristic "twist," but the operation is essentially subservient to the fermentation process which is an oxidation of the cell-contents of the leaf. The rolling ruptures the leaf-cells and the juice (sap) is pressed out on to the surface of the tissue where, under the influence of the oxidising enzyme (oxidase) present, its constituents combine with the oxygen of the air. This is the commencement of the fermentation.

(3) *Fermentation.* This process is designed to encourage the chemical action initiated during the rolling. The leaf removed from the rolling machines is transferred to the darkened fermenting rooms where it is spread out in layers 1 or 2 inches thick to give full access to the air which is freely admitted. In large factories special fermenting floors made of cement, tiles or plate glass squares, which can be readily sterilised when necessary, are used. The atmosphere of the room is kept moist usually by suspending wet cloths or by mechanical water sprays. During fermentation the leaf colour changes to a bright copper shade. The colourless "tannin" present becomes partly oxidised into reddish-brown products, giving "body" and colour to the tea liquor; while the characteristic odour and flavour of tea are also developed. The oxidation, however, must not be allowed to proceed too far or the quality of the tea is affected as a result of an excess production of insoluble brown substances. Investigations have shown that a number of micro-organisms (chiefly yeasts and bacteria) are always present in fermenting tea leaf. The organisms are present on the fresh leaf and increase during the withering and fermentation. Improvement in the flavour and aroma of the tea appears to be associated with increased numbers of yeast cells. It is possible to improve the qualities of the tea by the use of cultures of "pure" selected yeasts.

(4) *Firing or Drying.* The action of the oxidising enzyme is arrested at the desired moment by means of heat. The fermenting leaf is transformed to machines ("tea driers") where it passes automatically over a series of moving "tables" in the drying chamber through which hot air is passed. The firing is completed in about half an hour, though a second firing may be necessary. The firing arrests fermentation by the destruction of the enzyme and also dries the tea.

(5) *Grading.* The fired tea is subsequently sifted into grades which in the main correspond to the size of the leaf. The four chief grades of black tea, arranged in descending order of quality are Orange Pekoe, Pekoe, Pekoe Souchong and Souchong, the first-named being the youngest leaf.

The graded tea is stored in air-tight receptacles until it is required for packing. Previous to the latter it is again dried by machinery (the final firing) and is then ready for packing in the familiar lead-lined chests which are now usually made of three-ply wood.

GREEN TEA.—In making green tea the primary object is to prevent the occurrence of the chemical changes which take place in the withering and fermenting processes of black tea manufacture. The plucked leaf is therefore subjected to heat as the first process in the manufacture, with a view to the destruction of the oxidising enzyme in the leaf tissue. In China the method is by heating in cast-iron pans, but in India and Ceylon, where green tea is also made on a small scale, the plucked leaf is placed in a cylindrical steam heater for one or two minutes. Subsequently the moisture is removed in a centrifugal machine and the leaf subjected to a short and light rolling. The green tea is then fired (dried), graded and packed as in the case of black tea. The total tannin in green tea is higher than that in black tea made from similar leaf This results from the fact that, during the fermentation of black tea, a proportion of tannin is converted (oxidised) into red and brown substances which are not extracted by hot water (S E. C.)

TEA: CONSUMPTION AND TRADE. The world's annual consumption of tea is in the region of 900 million pounds. This is exclusive of the tea consumed by the population of China which, in the nature of things cannot even be estimated.

The sources of supply, with their fluctuations during the last thirty years, may be gauged from the following table:

Exports of Tea

Year	*India	†Ceylon
	Pounds	Pounds
1896–7	150,421,245 (100)	110,005,194 (100)
1905–6	214,224,000 (142)	170,184,000 (154)
1915–6	338,470,000 (225)	215,633,000 (195)
1925–6	325,733,000 (216)	209,700,000 (190)
1926–7	349,264,000 (233)	217,082,000 (197)
	China	**Java**
1896–7	240,106,266 (100)	
1905	132,367,000 black and green; 61,494,000 brick, tablets and dust (80)	25,650,156 (100)
1915	143,662,000 black and green; 93,777,000 brick, tablets and dust (98)	101,603,000 (400)
1925	88,020,000 black and green; 23,048,000 brick, tablets and dust (46)	94,774,000 (376)
1926	82,897,000 black and green; 29,012,000 brick, tablets and dust (46)	118,713,000 (472)

*India, fiscal year
†Ceylon, calendar year as in left hand column.

(The percentage figures have been added in brackets for the sake of comparison) India and Ceylon, as sources of the world's tea supplies, show a steady increase Java, thanks to the energy and enterprise of the Dutch, exhibits a remarkable advance

The acreage under tea in India during the same period with the production therefrom is shown by the following table:

Year	Acreage	Production
		lbs.
1895–9 (average)	467,291	158,375,000
1906	532,208	241,077,000
1915	634,940	372,203,000
1926	739,700	392,918,000

In 1927, Ceylon produced 226 million pounds of tea from 403,000 acres. Java and Sumatra together produced, 136 million pounds from 250,000 acres.

Japan's production was in the same year 176,153 piculs, equal to 23½ million pounds, very little of which found its way into the United Kingdom. The Island of Formosa (Japanese) produced 22 million pounds in 1925, mostly Oolong.

Of the varieties of tea, the great proportion produced in British India and in Ceylon is good, sound black tea. Thus, while India exported 360 million pounds of black during the season 1927–8, only 945,000 pounds of green left the country. During 1927, the proportions exported from Ceylon were 225 million pounds of black to about 2 million pounds of green. The latter figures compare with over 5 million pounds of green in 1913, a symptom of the general decline in the taste for green tea. The export of tea from China is divided into several kinds. Thus in 1926, the proportions were: black, 39 million pounds; green, various sorts, 43 million pounds; brick and tablet (mostly exported to Russia through North Pacific ports) 18 million pounds; other sorts, including unfired, scented, siftings, dust and stalk, 10 million pounds.

Of the smaller producing states, it is noteworthy that Nyasaland sends small quantities to the British market, nearly a thousand packages having been sold during the first half of the year 1928. Kenya Colony had in 1927, 3,156 acres under tea, producing 8,700 lb.—a pioneer industry which is likely to expand. Other centres of production for local consumption are Natal, Persia, the Caucasus, Annam, Burma, Palestine, and even the southern part of the United States. The quantity is very small in each case.

Importation and Consumption.—Great Britain and Northern Ireland consume more tea than all other countries combined. On the authority of the Tea Brokers' Association of London the following figures of imports are given:

Imports of Tea for Home Consumption

Countries	1927	1926
	lbs.	lbs
Great Britain and Northern Ireland	416,152,552	408,836,871
United States of America	88,518,696	95,926,377
Australia	49,672,000	46,950,000
Canada	38,116,897	37,629,652
Russia (European)	35,794,450	31,768,607
Irish Free State	23,767,045	23,596,281
Holland	22,453,000	21,153,000
Persia	12,000,000	12,341,617
Union of South Africa	11,812,072	10,303,132
Germany	11,409,361	10,115,689
Morocco	11,000,000	11,183,672
New Zealand	10,827,381	10,863,556
Countries consuming less than ten million pounds	60,825,046	57,872,385
TOTAL	792,348,500	778,540,839

(The figures for 1926 are revised those for 1927 provisional)

Of the total imports of tea into Great Britain and Northern Ireland in 1927,—539,348,620 pounds valued at £41,751,333—416,152,552 pounds were retained for home consumption. The sources of this tea were as follows:

Importation of Tea for Home Consumption into Great Britain and Ireland, 1927

From	Quantity
	lbs.
British East Indies (except Ceylon)	232,534,080
Ceylon	109,754,985
China, including Hongkong and Macao — black	10,567,308
China, including Hongkong and Macao — green	82,289
Java, Sumatra and other Dutch Possessions and Netherlands	61,240,148
Other countries	1,973,742
	416,152,552

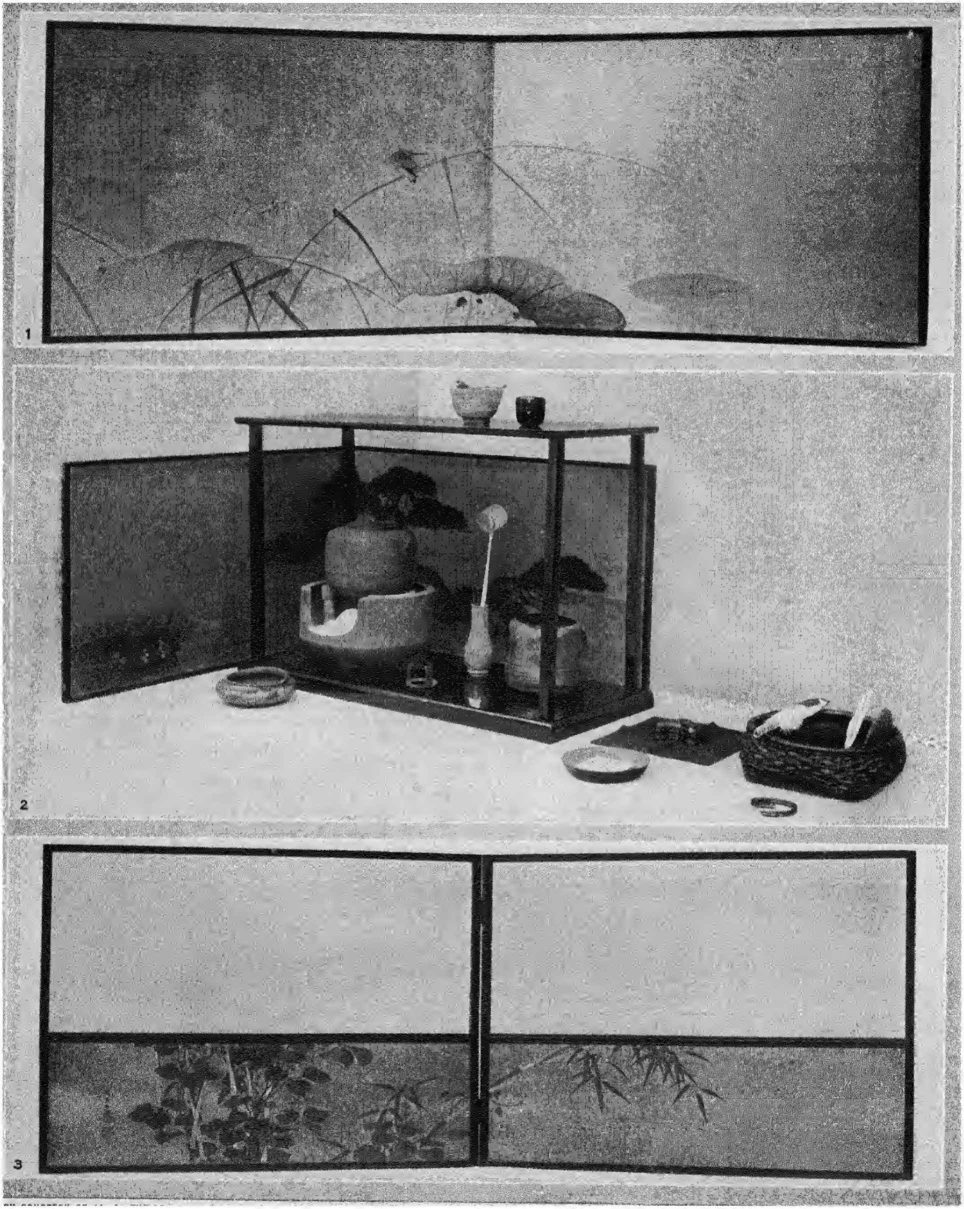
TEA DRINKING AND TEA DRINKING UTENSILS

1. *Koi-cha* (thick tea). Head guest receiving bowl from hostess
2. *Usu-cha* (thin tea). Host drinks tea after guests have finished
3. Japanese hostess brewing tea. Note the beautiful arrangement like a picture
4. *Chaseki*, a tea house, in the garden of Katsura Detached Palace in Kyoto
5. Stoneware tea caddy
6. Iron hot water kettle with oven
7. Porcelain tea caddy containing pulverized tea leaves
8. Ceramic tea pots and bags in which they are kept
9. Pottery jar used for holding water for washing tea bowl after each guest drinks
10. Carved lacquer incense box containing tea ceremony incense
11. Pottery tea bowl
12. Ornamental iron hot water kettle



BY COURTESY OF (1, 3) THE TOKYO IMPERIAL HOUSEHOLD MUSEUM, (2) THE METROPOLITAN MUSEUM OF ART, NEW YORK

TEA SET AND SCREENS USED IN THE TEA CEREMONY

1. Tea-screen painted in black monochrome on gold by Hashimoto Gaho, 20th century. Height, about 2½ ft.; length of each panel, 3 feet.
2. Tea ceremony set. On top of the table are a tea caddy and a tea bowl. On the lower part a covered iron kettle stands on a fire-iron in the iron fire-pot, in which ashes are built up to receive the coal. To the right is an incense box on a silk napkin, a cake dish and a coal basket containing the charcoal, the mat to set the kettle on, and the feather to brush the ashes
3. Tea screen by Ko Sukoku (1730–1804), painted in colour suggesting mists in gold dust. Height, 10 in.; length of each panel, 3 feet

METHOD OF PREPARING TEA FOR THE TEA CEREMONY

1. The host has just brought in a basket of charcoal to replenish the fire in the brazier and a can of incense to perfume the room. The charcoal is manipulated with a pair of iron sticks like chop sticks and so placed that it will ignite and burn quickly
2. Having brought everything in to the *chaseki* (*see* fig. 4, Plate I.), the host is sitting in front of the iron kettle, making obeisance before proceeding to prepare the tea
3. Picking up the dipper of bamboo, which he holds before him as he would a mirror, he is about to remove the lid of the kettle
4. Pouring hot water into the tea bowl, to rinse it with the aid of the whisk, which is to be used for stirring the pulverized tea in hot water
5. About to take the lid off the water jar. Of many ways in which the lid may be removed, etiquette permits only one, the most beautiful. Each movement must be beautiful, not only in itself, but in its relation to that which precedes and follows it
6. Having placed some pulverized tea in the bowl, the host is taking up the dipper to get hot water from the kettle to pour over the tea which will then be whipped with the whisk already rinsed

PLATE IV

TEA CEREMONY

BY COURTESY OF JIRO HARADA

ETIQUETTE OBSERVED BY HOST AND GUEST IN THE TEA CEREMONY

1. After having eaten the sweet, the guest receives a bowl of tea, places it on the mat upon which he sits, and makes obeisance to the host before taking it up to drink
2. The guest bringing the bowl of tea to his forehead in token of respect before proceeding to drink. His mind should be so attuned to higher things that it may be susceptible to any aesthetic suggestion the bowl of tea may induce
3. The host about to offer another bowl of tea to the guests who, having finished their tea, persuade him to partake of it, having placed the sweets near him
4. Correct manner of holding tea bowl. It is held securely in both hands, a perfect balance being essential to the maintenance of the mental equilibrium. The beauty of the green beverage, whose bubbles may suggest the effervancence of life, should not escape the notice of him who drinks
5. Drinking the tea in three sips and a half, the last being accompanied by an appreciative sound of drawing the last drop. After wiping the edge where his lips touched, he looks into the bowl at the tea design, which may possibly give him a clue for an aesthetic contemplation
6. End of the tea ceremony. The host is about to open the sliding door to take away the utensils from the *chaseki*. Etiquette requires that he be kneeling when opening or shutting the sliding screens

Tea Consumption per Head.—The present per capita consumption, in the principal consuming countries of tea in pounds per head, arrived at by dividing the figures as given above for home consumption by the latest ascertainable number of the population, is as follows: Great Britain and Northern Ireland, 9·4; New Zealand, 9; Australia, 8·3; Irish Free State, 7·6; Canada, 4; Holland, 3·2; South Africa, 1·7; United States of America, ·84; European Russia, ·27; Germany, ·18; France ·07.

Value of Imports and Duty.—The average landing values of tea in the United Kingdom for the following years may be compared:

Country	1899	1913	1916	1927
	d. per lb.	d. per lb.	d. per lb.	d. per lb.
India	9·25	9·24	11·25	19·06
Ceylon	8·80	9·04	11·49	20·20
China	7·24	9·00	11·22	16·31
Java and Netherlands	..	8·03	10·68	14·22

The duty since 1900, when it was raised from 4d. to 6d. per lb., has been as follows: 1904, 8d.; 1905, 6d.; 1906, 5d.; 1914, 8d.; 1915, 1s.; 1919, 10d. British grown, 1s. foreign grown; 1922, 6⅔d. British grown, 8d. foreign grown; 1924 and since, 3⅓d. and 4d.

How Consumed.—In Great Britain, Ireland and the British Dominions, tea is drunk simply as an infusion and usually with milk and sugar. In Russia, the samovar is traditional and a pot of strong China tea is made. A little of the liquor is put in a glass and filled up with boiling water from the samovar, and a spoonful of jam or a slice of lemon, and a lump of sugar added. In America, iced tea is a hot-weather drink. (C. L. T. B.)

TEA-CADDY, a box, jar, canister or other receptacle for tea. The word is believed to be derived from *catty*, the Chinese pound, equal to about a pound and a third avoirdupois. The earliest examples that came to Europe were of Chinese porcelain, and in shape resembled the ginger-jar. They had lids or stoppers likewise of china, and were most frequently blue and white. The English kilns at first imitated them, but speedily devised forms and ornament of their own, and there was hardly a ceramic factory in the country which did not compete for the supply of the new fashion. But tea-caddies were not for long confined to porcelain or faience. They were presently made in a variety of materials, and in an equal variety of shapes. On the whole the mahogany or rosewood caddy of the latter part of the 18th and the early years of the 19th century was, from the artistic point of view, the most elegant and satisfying.

TEA CEREMONY is a time-honoured institution in Japan—an institution rooted in the principles of Zen (a sect of Buddhism) and founded upon the adoration of the beautiful in the daily routine of life, such as preparing a meal and tea, cleaning the house and garden, etc. The Japanese word for tea ceremony, *Cha-no-yu*, literally hot water of tea, means an aesthetic way of entertaining guests, usually five at a time, with thick and weak tea of pulverized tea-leaf whipped in hot water, preceded by a meal, according to the established rules of etiquette. The entertainment takes place in the tea-room (*chaseki*), usually a small building constructed to suggest a refined poverty, though with great forethought and after endless trouble in the choice of the material and in the construction. The room in which the guests are entertained is generally about 9 ft. square, or smaller, containing an alcove for ornaments and a small fire-place for boiling the kettle, sunk into the floor. Into that room each guest in humility crawls through a small opening less than 3 ft. square. It is connected with the waiting room by stepping stones through a garden path (*roji*), which should contain a water basin (*tsukubai*) for the guests to rinse mouth and wash hands before entering the tea-room.

In this ancient institution—for it was founded under the Shogun Yoshimasa (1449–73) and perfected by Sen-no Rikyu in the 16th century—which still continues to influence the life of the Japanese people and all their art, the spirit of old Japan still lives.

TEACH [Thatch or Thach], **EDWARD** (d. 1718), English pirate, popularly known as Blackbeard, is believed to have been born at Bristol. He is said to have gone out to the West Indies during the war of the Spanish Succession, to have engaged in privateering, and after the declaration of peace (1713) to have turned pirate, but he is not actually heard of in this capacity till the end of 1716. The following year he captured a large French merchantman, rechristened her "Queen Anne's Revenge," and converted her into a warship of forty guns. His outrages in the Spanish main, the West Indies, and on the coasts of Carolina and Virginia, quickly earned him an infamous notoriety. He made his winter quarters in an inlet in North Carolina, the governor of which colony was not above sharing in the proceeds of his crimes, but the governor of Virginia at last despatched two sloops, manned from the British warships on the station, to cut him out. On Nov. 22, 1718 Lieutenant Maynard boarded Teach's sloop, after a sharp fight, and himself shot the pirate dead.

TEACHERS, TRAINING OF. The training of teachers dates, in England, from the beginning of the 19th century, when the National Society for Promoting the Education of the Poor in the Principles of the Church of England and its Nonconformist rival, the British and Foreign School Society, first attacked the problem of elementary education on a national scale. Both these societies adopted the "monitorial system," the principle of which was that picked older scholars should learn their lessons from the adult teacher in charge of the school and hand them on to the younger children. Some training of the instruments of this system was found to be necessary and training schools were accordingly set up to give it. One of these developed into the Borough Road training college which is still in existence. About 1840 James Kay (afterwards Sir James Kay-Shuttleworth), a far-seeing official to whom, more than to any other single man, the English educational system is due, began the movement which replaced the monitors by "pupil-teachers," *i.e.*, boys and girls who were regularly apprenticed for a period of five years from the age of 13, and both learnt the art of teaching and continued their education under the head teacher of an elementary school. Kay's scheme also involved training colleges where the professional and academic education of at least the best pupil-teachers could be carried to a higher stage after their apprenticeship was completed. He himself founded the college which, as St. John's College, Battersea, London, was taken over by the National Society and furnished a model widely imitated. Within a few years the Church had training colleges in a large proportion of its dioceses and there was a smaller number of others founded by Nonconformist bodies. As the result of Kay-Shuttleworth's efforts these colleges came into a definite relation with the Government; they received financial assistance towards the cost both of building and of maintenance, a competitive examination was instituted upon the results of which "Queen's Scholarships" were awarded to ex-pupil-teachers who came to them for a period of training, and contributions were made to the salaries of the teachers they turned out. As a condition of this financial aid to the colleges and their students, the Government laid down the courses to be followed, conducted the examinations on the results of which it awarded to successful candidates its Elementary School Teacher's certificate and required the colleges to submit to inspection.

The "voluntary" colleges which developed upon this basis became and are still a very important factor in the elementary school system. They now number nearly 50 and supply about one-half of the trained teachers who enter the elementary school service. At the beginning of the present century the length of their course became standardized at two years; they are, accordingly, known officially as two year colleges.

The monopoly of training enjoyed by the colleges was broken in 1893, when new regulations made it possible for the universities to open grant-aided departments for the training of teachers for elementary schools. All the universities and university colleges, to the number of 22, have taken advantage of these regulations. The Education Act of 1902 made it possible also for local educational authorities to found and maintain training colleges. There are now about 20 of these "council" training colleges and their

annual output of teachers is more than half that of the "voluntary" colleges. They differ from the latter type of colleges in the absence of any religious affiliation and in the circumstance that they are often "day" as distinguished from "residential" colleges.

The act of 1902 produced a much more important modification of the existing system in that it led to drastic changes in the education of pupil-teachers Under the act the local authorities were given powers in connection with secondary as well as elementary education and could establish secondary schools. It thus became possible for the Board of Education to insist that entrants to training colleges should normally have taken a four year course in a secondary school. The effect of this reform upon the culture and outlook of the elementary school teacher—who had hitherto spent his life, as a rule, within the confines of the elementary system—has without doubt been beneficial in a very high degree. It has also led to the gradual disappearance of the pupil-teacher system, now only in vogue in some country areas; for as the customary standards of secondary education have risen it has proved impossible for the young intending teacher to comply with them, and at the same time to receive the old thorough training in teaching In recent years pupil-teachers have, accordingly, tended to give place to "student-teachers," who have had an uninterrupted general education until the age of 17, and at that age enter upon a year of preliminary training in an elementary school chequered by continued attendance at their secondary school But the departmental committee on the training of teachers for elementary schools reported in 1925 against the perpetuation even of this remnant of the old system; and although many of the provincial authorities still cling to a belief in its efficacy there is a growing tendency to follow the recommendations of the report and to allow intending teachers to complete the full secondary course terminating at the age of 18, and to enter college without passing through any considerable period of professional probation or initiation. The advantages looked for are a still wider and deeper culture in the teachers and the preservation of a power of growth which the older system, it is alleged, often destroyed; it is, on the other hand, only fair to note that the strain upon the disciplinary powers of the young teacher —which only the drastic training of the old system could enable him to meet—has largely disappeared under modern conditions

The curriculum in the two year colleges has always included academic and professional elements side by side, though with the improvement in the educational standard of the entrants and the attenuation of their preliminary training there is a growing tendency to emphasize the professional side of the work. The academic studies are practically confined to subjects which enter into the curriculum of elementary (including central) schools; the professional work comprises instruction in the theory of education, methods of teaching, hygiene, practical subjects such as music, drawing and needlework, and teaching practice under supervision in schools. Hitherto the curricula have been laid down by the Board of Education and the board has, as a rule, conducted the final examination with a view to the award of the Elementary School Teacher's certificate. A change which must have far-reaching consequences is, however, now in progress. The board's examination is to be discontinued, the training colleges have been classified into groups around the several regional universities, and the universities will, with varying degrees of fullness of responsibility, step into the place which the board has vacated. Boards or delegacies, either appointed by the universities or largely filled by their representatives will conduct the final examination and, as an inevitable corollary, will prescribe the syllabuses of instruction The Board of Education will, however, retain the right of judgment of the efficiency of the practical training given by the colleges. It is hoped in some quarters that intimate and fruitful relations between the colleges and the universities may develop from their association in the work of examination.

During the present century there have been important developments in the training departments of the universities. These were established to enable a select number of intending elementary school teachers to come under the broadening influences of university life and teaching; they have developed into institutions by whose aid future teachers in secondary and elementary schools may obtain a university degree and professional training. For some years the maximum length of the course was three years and professional training was given concurrently with the student's academic studies. It was, however, found that the full value of the scheme could not thus be obtained; the course was, accordingly, extended to four years, of which the first three are devoted practically entirely to preparation for a degree while the last is given wholly to a course of professional training comprising much the same elements as the professional course in the two year colleges. Students admitted to the four year course receive free academic teaching and professional training and, like the two year students, also receive an annual grant for maintenance from the Board of Education.

The original theory of the four year course was that it was to supply the elementary school system with teachers of superior ability, education and training; but a very large proportion of the graduates it turned out actually found their way into secondary schools Eventually the board recognized the situation officially. It extended its grant system to include graduates in honours in the secondary training departments of the universities, and permitted four year students who had taken a degree in honours at the end of the third year to be transferred to those departments So slight a change in official regulations has not often produced greater consequences Formerly training expressly intended to fit teachers for secondary school work was an almost negligible factor in the English system; now some hundreds of young men and women, graduates in honours who have received such training, are entering the secondary schools annually from the universities. *See* also EDUCATION: *England* (T P. N)

France.—Elementary teachers are generally recruited from the higher elementary school They enter the training college at the age of 15 after passing the *brevet simple* or its equivalent and after a three year course take the *brevet supérieur,* and a test in teaching. All State teachers have to be trained In the non-State schools the head alone of the teachers has to possess the *brevet simple.* Secondary teachers in the other classes of the *lycées* generally recruited from the *école normale supérieure,* have to pass the *agrégation,* a stiff competitive examination in knowledge and the art of setting forth a subject; teachers in the other classes are not obliged to be trained, their academic qualifications are deemed sufficient; teachers in the preparatory classes must possess the elementary certificate.

Germany.—Elementary teachers attend the ordinary training college. Those who teach in the secondary schools undergo a severe apprenticeship in the school to which they are attached, and pass an examination conducted by the Government inspector.

BIBLIOGRAPHY.—Lance Jones, *The Training of Teachers in England* (1923); Frank Smith, *The Life of Sir James Kay-Shuttleworth* (1923); *Report of the Departmental Committee on the Training of Teachers for Elementary Schools* (1925). *See* also EDUCATION; EXAMINATIONS (X.)

NORMAL SCHOOLS AND TEACHERS' COLLEGES IN THE UNITED STATES

Teacher training schools in the United States, exclusive of departments of education in colleges and universities, fall into five general classes. State normal schools, State teachers' colleges, city normal schools and teachers' colleges, county normal schools and high schools and private normal schools The first school for the preparation of teachers was opened at Lexington, Vt., in 1823 by Rev. Samuel Reed Hall, who had been a teacher as well as preacher, and who accepted the pastorate of the Congregational Church at Lexington on condition that he might conduct a seminary for teachers. The school continued for seven years.

State Normal Schools.—Massachusetts was the first State to establish normal schools James G. Carter, who is called the "father of normal schools," being primarily responsible. Through his influence the State Board of Education of Massachusetts was established and the normal school bill was passed in 1838. Three normal schools were established, the first being opened at Lexington in 1839. New York established a normal school at Albany in

1844; Connecticut and Michigan authorized normal schools in 1849 and the Connecticut school opened the same year, the Michigan in 1852. In 1928 all but five of the 48 States have State teachers' colleges or normal schools.

Normal schools were established for the purpose of training teachers for the common schools, which generally meant the ungraded schools. The curriculum of the normal school at Lexington provided for a study of "all the common branches, particularly and fully; together with composition, geometry, algebra, physiology; natural, intellectual and moral philosophy; botany, political economy, bookkeeping, vocal music and the art of teaching."

State Teachers' Colleges.—The rise of many normal schools to the rank of teachers' colleges was a natural result of the development of education and especially of the remarkable growth of the high school. From the very first some of the normal school graduates, especially in the middle West, found their way into high schools; entrance requirements were gradually advanced, and in some the curriculum was extended to four years. In 1893 the Normal school at Albany became the Albany State Teachers' college and began to confer degrees. In 1897 the Michigan State Normal school became the Michigan State Normal college and was given the power to grant degrees. Other States in the middle West soon followed. The World War stimulated greatly the development of the teachers' colleges, for the lack of teachers called attention to the institutions which were largely responsible for training them. In 1920 the (U.S.) bureau of education listed 46 teachers' colleges, four of which were private institutions; in 1922 the number had increased to 80, in 1924 to 88, and in 1926 to 101. Since the 1926 bulletin was published several States have advanced their normal schools to full collegiate rank.

Other Normal Schools and Teachers' Colleges.—County normal schools were organized to supplement the State normal schools in the preparation of teachers for the rural schools. The curriculum in some States is one year beyond high school and in some two years. Among the States which have such institutions are Michigan, Wisconsin and Nebraska. In 1926 every State with the exception of New Hampshire reported teacher training in high schools. In a majority of instances the training is a part of the high school course. In other instances it is preceded by high school graduation. In some States the county normal organization is separate and apart from the public school system.

City normal schools or teachers' colleges have been established in connection with many of the larger city school systems. The length of the curriculum varies from two to four years. Institutions giving a four year course are generally called teachers' colleges and some grant the collegiate degree.

The private normal schools, of which the Bureau of Education lists 64, are largely schools for the training of teachers of physical education and for the kindergarten and primary grades. Most of these schools are associated with religious organizations. The curriculum of study is generally two years in length. (C. McK.)

TEACHERS' PENSIONS: *see* Pensions in the United States; Pensions: *Civil Service, Municipal.*

TEACHERS REGISTRATION COUNCIL. Originally authorized by the English Education (Administrative Provisions) Act of 1907, the Teachers Registration Council was established by an Order in Council of Feb. 29, 1912. It consisted of 44 members, all of whom were teachers or persons recently engaged in teaching. These members were elected by the appointing bodies named in the first schedule of the Order in such a manner that eleven universities and 42 associations of teachers were represented on the council, 11 members being drawn from each of the four main groups of teachers.

Under a new Order, officially known as the "Teachers Registration Council Order, 1926," the number of the council may be increased to 50. There are four groups representing, respectively, university teachers, teachers in public elementary schools, teachers in secondary schools, specialist teachers with teachers in technical institutes, and each group is represented by 12 registered teachers engaged in the type of teaching work to which the group belongs. These 48 elected members may, if they choose, co-opt two additional members to represent any type of teaching work which, in their opinion, is inadequately represented among their own number. The period of office for each Council has been extended from three to five years. The 12 university members are appointed by the 12 universities now existing in England and Wales.

Representatives of teachers other than university teachers are elected directly by the registered teachers of the country, who vote according to the types of teaching work to which they belong, and have a number of votes equal to the number of representatives assigned to that particular type in the Order.

For admission to the register, the council has framed conditions which must be fulfilled by all applicants. The great variety of examinations in special subjects renders the task of standardization very difficult, but already the council has established standards of attainment and of professional training in connection with the teaching of such subjects as music, art, handwork and domestic science. The main principle that is being kept in view is that no one should be permitted to become a fully recognized teacher, or to claim professional status who has not undertaken a suitable course of study and a course of training in the art of teaching.

The council has recently taken steps to bring within its purview not only those who are eligible to become registered, but also those who are likely to become eligible, by the institution of a list of associate teachers, open to all who have passed an approved entrance examination. The council has decided to remove from the list of associate teachers all who do not become fully registered within seven years of their admission to the list. (G.)

In the United States there is no teachers' organization that corresponds to the Teachers Registration Council. There the governmental agencies certificate teachers directly, and there is no register kept except the list of persons who have been granted governmental certificates.

TEACHING, METHODS OF, for countries other than the United States *see* Education. The following section deals with a special phase of educational methods in the United States.

American students of education define teaching as the learning process. To promote the learner's growth is the teacher's objective, but growth, it is contended, results only from the activity of the learner himself. American educational theory looks upon the direct imparting of knowledge as a subordinate rather than a major function of the teacher. Especially does it condemn the "lecture method," and in the elementary and high schools anything resembling this method has long been taboo. The use of textbooks has been subjected to serious criticism, although the prevailing "pattern" of teaching still comprises (1) assignment of a textbook lesson, (2) independent study of the lesson by the pupils and (3) a class meeting or recitation for testing the pupils' efforts to learn the assigned materials.

Late in the '90s, the Herbartian "developmental" method was brought to the attention of American teachers through the writings especially of Charles DeGarmo and Charles A. and Frank M. McMurry. As crystallized in the "five normal steps of the recitation," developmental teaching aimed to lead the learner to make his own inferences and formulate his own conclusions, after a careful study of the facts in each case. This method also emphasized the importance of having the learner conscious of the aim or purpose of each lesson.

The "problem" method, in part an outgrowth of the Herbartian movement, gained its chief support from other sources. The theories of Froebel, at first limited in their application to the kindergarten (*q.v.*), tended to emphasize throughout the field of elementary education the importance of "doing" as contrasted with "knowing." Manual training, introduced as a complement to and corrective of mental training, was gradually integrated with the latter; problems of construction in the workshop provided a field of application for the lessons of the classroom, and the needs of construction furnished motives for learning new lessons. John Dewey's insistence that school is life rather than merely preparation for life also encouraged the educational use of problems that arise in the everyday experience of children. The development of a dynamic psychology added strength to the growing conviction that knowledge may be most effectively

brought to the learner, not in a logically organized form, but rather in the context of real problems and as a means of meeting real needs and conquering real obstacles.

The "project" method has been the natural outcome of this increasing recognition of the problem as the basic unit in teaching and learning. Long used in schools of architecture, the term "project" was taken over by secondary vocational education about 1912 and applied particularly to "home projects" in agriculture and the household arts. The conception of the project as a relatively large problem "carried to completion in its natural setting" was amplified by Werrett W. Charters and John A. Stevenson and applied to educational fields other than strictly vocational. Under this conception, a large problem arising under conditions closely approximating those of real life may become the centre around which can be organized some of the skills, facts and principles the learner is expected to master.

A less restricted conception of the project method has been developed by William H. Kilpatrick. In Kilpatrick's theory, the essential characteristic of a true project is not to be sought in any set of objective conditions, but rather in the attitude of the learner toward his learning activities Some advocates of project teaching hold that the teacher's primary duty is to watch for these learning activities, to seize upon such of them as are worthy, and then to guide the learner toward their realization. According to this view all learning activities should originate in the learner's own spontaneous purposes and any imposition of learning tasks by the teacher would be an injustice. This limitation obviously excludes assigned lessons or prearranged courses of study. In fact a radical wing of the project group would have the school curriculum grow from day to day—even from hour to hour—in response to the interests and purposes of the learner.

While the theory of project teaching has had a pronounced vogue and is, indeed, the central and dominant doctrine of the "Progressive Education" (*q.v*) movement, certain other proposals, not in harmony at all points with the project theory, have attracted attention The plans for intensive individual instruction proposed by Mrs. Helen Parkhurst (the Dalton plan) and Carleton W. Washburn (the Winnetka plan) give a central place to carefully organized and closely articulated subject-matter assignments which the learner masters *seriatim*, progressing at his own rate but having advice and guidance from the teacher.

Closely related to these plans are the numerous devices for promoting individual learning developed as a result of the testing movement: practice exercises which provide drill on the essentials of arithmetic and language; remedial exercises to correct the weaknesses revealed by diagnostic tests; and "self-administered" measures of various types which enable the learner to note the progress that he makes. These devices provide "problems" for learning, as do the assignments of the Dalton and Winnetka plans, but not the type of problem that the project theory emphasizes.

TEAK, one of the most valuable of known timbers. The Sanskrit name of teak is *saka,* and it is certain that in India teak has been known and used largely for more than 2,000 years. Teak is a large deciduous tree, of the family Verbenaceae, with a tall, straight but often buttressed stem, a spreading crown, and the branchlets four-sided with large quadrangular pith. It is a native of the Indian peninsula, Burma and Siam, and is also found in the Philippine islands, in Java and elsewhere in the Malay archipelago, although there is no record of its being native in these places. In India proper its northern limit is 24° 40′ on the west side of the Aravalli hills, and in the centre, near Jhansi, 25° 30′ N. lat. In Burma it extends to near Myitkyina, in lat 25° 30′. In Bengal or Assam it is not indigenous, but plantations have been formed in Assam as far as the 27th parallel. In the Punjab it is grown in gardens to the 32nd. Teak thrives best in districts with a mean annual rainfall of more than 50 in. The mean annual temperature which suits it best lies between 75° F and 81° F. Near the coast the tree is absent, and inland the most valuable forests are on low hills up to 3,000 ft. It grows on a great variety of soils, but there is one indispensable condition—perfect drainage or a dry subsoil. On level ground, with deep alluvial soil, teak does not always form regularly shaped stems, probably because the subsoil drainage is imperfect.

During the dry season the tree is leafless; in hot localities the leaves fall in January, but in moist places the tree remains green till March At the end of the dry season, when the first monsoon rains fall, the fresh foliage comes out The leaves, which stand opposite, or only whorled in very young specimens, are from 1 to 2 ft. in length and from 6 to 12 in. in breadth. On coppice shoots the leaves are much larger, and not rarely from 2 to 3 ft. long. In shape they somewhat resemble those of the tobacco plant, but their substance is hard and the surface rough. The small white flowers are very numerous, on large erect cross-branched panicles, which terminate the branches

The tree seeds freely every year, but its spread by self-sown seed is impeded by the forest fires of the dry season, which in India generally occur in March and April, after the seeds have ripened and have partly fallen. Germination is slow.

The bark of the stem is about half an inch thick, grey or brownish grey, the sapwood white; the heartwood of the green tree has a pleasant and strong aromatic fragrance and a beautiful golden-yellow colour, which on seasoning soon darkens into brown, mottled with darker streaks. The timber retains its aromatic fragrance to a great age.

Durability of Teak.—The principal value of teak timber for use in warm countries is its extraordinary durability In India and in Burma beams of the wood in good preservation are often found in buildings several centuries old, and instances are known of teak beams having lasted more than 1,000 years In one of the oldest buildings among the ruins of the old city of Vijayanagar, on the banks of the Tungabhadra in southern India, the superstructure is supported by planks of teakwood 1½ in thick These planks were examined in 1881; they were in a good state of preservation and showed the peculiar structure of teak timber in a very marked manner. They had been in the building for 500 years (*Indian Forester*, vii. 260). In the wall of a palace of the Persian kings near Baghdad, which was pillaged in the 7th century, two Americans found in 1811 pieces of Indian teak which were perfectly sound (Ouseley, *Travels in Various Countries of the East,* ii 280, n. 67). In the old cave temples of Salsette and elsewhere in western India pieces of teak have been found in good preservation which must have been more than 2,000 years old.

Teak is used for shipbuilding, for furniture, for door and window frames, for the construction of railway carriages, and for many other purposes. White ants eat the sapwood, but rarely attack the heartwood of teak. It is not, however, proof against the borings of the teredo, from whose attacks the teak piles of the wharves in the Rangoon river are protected by metal.

Growth.—In its youth the tree grows with extreme rapidity. Two-year-old seedlings on good soil are 5 to 10 ft high, and instances of more rapid growth are not uncommon In the plantations which have been made since 1856 in Burma, the teak has on good soil attained an average height of 60 ft. in 15 years, with a girth, breast high, of 19 inches. This is between 16° and 18° N. lat, with a mean annual temperature of 78° F and a rainfall of 100 inches. In the Burma plantations it is estimated that the tree will, under favourable circumstances, attain a diameter of 24 in. (girth 72 in.) at the age of 80. Timber of that size is marketable, but the timber of the natural forests which is at present brought to market in Burma has grown much more slowly, the chief reason being the annual forest fires, which harden and impoverish the soil. In the natural forests of Burma and India teak timber with a diameter of 24 in. is never less than 100 and

often more than 200 years old. The trees are not generally more than 100 to 150 ft. high, even under favourable circumstances.

THE TEAK TRADE

While it is true that by far the largest volume of the teak wood produced is used in India and Burma, Ceylon, and the East, nearly all of the best quality is exported to other parts of the world, the demand from all countries having been on a continually increasing scale. Nearly all the produce of the forests of Travancore, Cochin, Madras Presidency, Coorg, Mysore, Bombay, Berar, and the Central Provinces is so consumed, although small supplies from Travancore and the Madras and Bombay Presidencies have continued almost annually to find their way to Europe. The actual output from Burma, shipped from Rangoon and Moulmein, far exceeds anything which is produced from any other source, the volume for 1926 being 550,000 loads. Next in volume is that produced in Siam and shipped from Bangkok: certain quantities have been regularly shipped from Java and Saigon, but of late the export from Java has been much restricted on account of the Dutch Government regulations.

The timber brought to the Burma ports is derived:—(1) from the forests in the British coast provinces, Pegu and Tenasserim; (2) from the forests in the former kingdom of Burma, floated to Rangoon down the Sittang and Irrawaddy rivers; (3) from the forests in the Shan States formerly tributary to Burma, from the Karenni country, and from western Siam, whence it is floated to Moulmein by the Salwin river.

In British India, including Burma, a large portion of the teak-producing tracts have since 1856 been placed under conservancy management with the object of preventing overcutting and maintaining a permanent and gradually increasing supply. Similar measures have been taken in Siam and in the teak-producing native States in the peninsula. The teak plantations in Java had come into bearing by 1908, and while it was expected at that time that teak might be produced from the Philippine islands, this expectation has not been fulfilled. (X.; A. L. H.)

TEAL, a small and beautiful duck, highly esteemed for the table. It inhabits the whole of Europe and Asia, visiting northern Africa in winter. In habits and nesting sites this species (*Anas crecca*) resembles the wild duck (*q.v.*) though it more often nests at a distance from water. It is replaced in North America by the green-winged teal, *A. carolinense* or *Nettion carolinense,* and in China by the Mandarin-duck, *Aix galericulata.* Hardly less showy than these are the two species of the subgenus *Eunetta,*—the Falcated duck, *E. falcata,* and the Baikal teal, *E. formosa.*

TEANO (anc. *Teanum Sidicinum*), a town of Campania, Italy, in the province of Frosinone, 21 m. N.W. of Caserta on the old main line to Rome from Naples, forming conjointly with Calvi an episcopal see. Pop. (1921) 9,154 (town); 11,683 (commune). It stands at the south-east foot of Rocca Monfina, 643 ft. above sea-level. There is a feudal castle built by the dukes of Sessa in the 15th century.

The ancient Teanum Sidicinum (there is a Teanum Apulum in Apulia) was the capital of the Oscan tribe of the Sidicini which drove the Aurunci from Rocca Monfina. Remains of the city walls, of a theatre and an amphitheatre still exist, and some extensive baths and some Roman dwellings, both some way below the modern town. A tomb with a mosaic representing the visit of the three kings to Bethlehem was found in 1907.

TEA-POY (Hindustani *tēpāi*), a small table, supported upon a tripod, for holding a tea-service.

TEAR GAS: *see* CHEMICAL WARFARE.

TEASEL. Wild teasel is a common plant of the English copses and hedges, with a tall, stout, rigid, prickly stem, bearing large spreading opposite leaves, the midrib of which is prickly, and conspicuous oblong heads, the purplish flowers in which are subtended by very long, narrow, stiff, upright bracts. The plant is known botanically as *Dipsacus sylvestris.* Fuller's teasel, *D. fullonum,* in which the bracts are hooked, is probably a cultivated form of the wild species; the dry heads are used to comb up the nap on cloth. The wild teasel is extensively and the fuller's teasel sparingly naturalized in the eastern parts of the United States.

TEA SHOP: *see* CAFÉ and CAFETERIA.

TEATE MARRUCINORUM: *see* CHIETI.

TEBESSA (the Roman Theveste), a town of Algeria in the department of Constantine, 146 m. S.E. of Bona by rail and 12 m. W. of the Tunisian frontier, on a plateau 2,950 ft. above the sea. Pop. 7,018, of which 1,614 are Europeans. The modern town, which is within the walls of the Byzantine citadel, boasts nothing of interest save a church built out of the ancient ruins. The Byzantine walls, pierced by three gates, are in tolerable preservation. They are strengthened by numerous square towers. One of the gates is formed by the quadrifrontal arch of Caracalla, a rare form of construction. The arch, erected A.D. 214, is in good preservation. A pair of monolithic columns, disengaged, flank each façade. The most important ruins are those of the great basilica. This building, one of the finest Roman monuments in Algeria, bears evidence of having been built at various epochs; the earlier portions probably date from not later than the beginning of the 2nd century A.D. The basilica was partially destroyed by the Berbers in the 5th century, and was rebuilt in A.D. 535 by the Byzantine general Solomon, who surrounded it with a wall about 25 feet high, still standing. The tessellated pavement which covers the basilica proper is in almost perfect condition. Next the basilica are the ruins of the forum.

Theveste was founded towards the close of the 1st century A.D. In the succeeding century it was connected with Carthage by a great highway. In the 5th century, under Vandal dominion, it declined in importance. Refounded by the Byzantines in the 6th century, the city disappeared from history at the time of the Arab conquest of the country in the 7th century. In the 16th century the Turks placed a small garrison of janissaries in the place, but Tebessa continued to be but a small village until the establishment of French rule. Near by are the phosphate quarries of Jebel Kouif, with annual output of 450,000 tons.

See Sir R. Lambert Playfair, *Handbook for Travellers in Algeria and Tunis* (1895), pp. 233–240, *Guides-Joanne, Algérie et Tunisie* (1928); Abbé Kopp, *Tébessa, guide historique* (Tebéssa, 1923); Pierre Castel, Tébessa, 2 vol.

TEBU ("Men of Tu," *i.e.,* "of the rocks"), a nomad negro-Berber race of the eastern Sahara. Their westernmost settlements are the oases of Agram, Kawar and Jebādo, their northernmost the district of Gatron (Qatrūn) within the Fezzan frontier, while south and south-east they merge in the negroid populations of Kanem, Bornu (Chad basin), Wadai and north-west Darfur. But the bulk of the nation is concentrated in Tibesti or Tu, hence their name. There are two main divisions—the northern Teda, or less negroid Tebu, and the southern Daza, or more negroid Tebu. Less closely connected are the Baele of the eastern and south-eastern oases and the Zoghāwa (Zaghwa) of Darfur.

The Tebu are usually identified with the Garamantes of Herodotus (iv. 183), whose capital was Garama (Idrisi's Germa) in Phazania (Fezzan), and of whom Ptolemy spoke doubtfully as Ethiopians (Negroes ?). But Leo Africanus transfers them to the Berber connection, whose fifth great division he deals with under the names of Gumeri (Garamantes ?) and Bardaei or Bardoa, that is, the Teda of the Bardai oasis, Tibesti.

TECHNICAL EDUCATION. Technical education (Greek τέχνη, art or craft) may be defined as the special training of persons in the arts and sciences that underlie the practice of some trade or profession. The description "vocational training" (*q.v.*) is often used, particularly in the United States, as an alternative; and when so used includes commercial education.

THE UNITED STATES

The first technical instruction in the United States appears to have been given in connection with the U.S. Military Academy, organized in 1802 at West Point. Naturally the instruction was concerned with military problems. In 1824 Rensselaer Polytechnic Institute was founded at Troy, N.Y., and started the work of training "civil" so called in distinction to "military" engineers. Rensselaer conferred its first engineering degrees in 1835. Harvard opened the Lawrence Scientific School and Yale established the Sheffield Scientific School in 1847. The University of Michigan began instruction in engineering in 1853.

In 1862 Congress passed the Morrill Land Grant Act and thus laid the foundation of the Land Grant colleges from which have grown the State universities The Act in setting aside public lands for the support of these colleges specifically prescribed that they shall teach "such branches of learning as are related to agriculture and the mechanic arts." Under the impetus of this Act and the economic pressure due to the needs of a new country engineering grew apace. The School of Mines at Columbia was founded in 1864, the Massachusetts Institute of Technology in 1865, Cornell University and Worcester Polytechnic Institute in 1868.

Technical education of university grade has grown therefore under two auspices, namely private ownership and State ownership. In the first group are to be found technical schools of high grade independent of general educational functions as illustrated by the Massachusetts Institute of Technology, and Rensselaer Polytechnic Institute. Again many large privately endowed universities such as Harvard, Yale, Cornell, etc., have engineering colleges which are integral parts of a group of colleges that comprise the university In some of the State universities the colleges of engineering and agriculture are separated from the general courses not only educationally but geographically as well. Thus the University of Michigan proper is at Ann Arbor, while the Michigan College of Agriculture and Mechanic Arts is at Lansing some distance away The increase in the number of technical schools of collegiate rank is noteworthy. In 1866 there were but six engineering colleges of established reputation and only 300 men had been graduated in the previous thirty-one years. In 1929 the U S. Bureau of Education listed 148 technical colleges with a total enrollment in 1928 of 65,520.

While there is considerable variation in the entrance requirements of this large group in general a high school education is required The colleges of highest grade require plane and solid geometry, advanced algebra and trigonometry, a certain amount of language training and sometimes elementary chemistry or physics in addition to such standard requirements as English, history, etc In general, the entrance requirements of the privately endowed colleges are somewhat higher than those of the State institutions, the latter from the nature of State educational systems being closely articulated with the high schools of the state.

There is also a singular degree of uniformity in the curricula of the better type of technical college. This is necessarily so in a measure since engineering is an application of the basic sciences of mathematics, physics and chemistry and their derivatives Analytic mechanics, which is a key course, is usually completed by the middle of the third year leaving at least one year and a half of the four year course for engineering fundamentals and applications. There is considerable variance however in the matter of instruction for specific technical callings. Practically all colleges recognize the three principal fields of engineering, namely, civil, mechanical and electrical. For the most part also the higher technical schools recognize the necessity of offering a limited amount of instruction in specialized fields such as heat-power, radio, industrial, hydraulic engineering, etc., in the senior year, usually as optional studies There is always, however, a strong pressure from the industrial field in the direction of highly specialized courses with their beginnings much earlier and not a few colleges have yielded to this pressure. For the most part, however, educators have become convinced that the student's time is best spent during the first three years, at least, in acquiring fundamentals Specialization should be deferred as long as possible and any extended special study should be carried to a fifth year study. All technical colleges of repute offer graduate study.

Until comparatively recent years the technical colleges were the principal centres of research work in engineering and the chief sources of engineering data The growth of commercial research laboratories has changed this situation but there is still an immense amount of research conducted in college laboratories. There is a growing tendency for industrial enterprises to co-operate with college laboratories in the prosecution of special problems. If properly conducted such joint efforts are most fruitful since the commercial concern can supply the practical data for the problem and the funds for its prosecution while the college can supply the necessary apparatus and knowledge.

The growing tendency of the engineer to take a leading place in industrial administration has given rise to a need for a broadening of the curriculum by the introduction of economics, accounting and subjects of a more liberalizing character such as history, etc. While a certain amount of such topics have been introduced into the standard four-year courses any great addition necessitates a lengthening of the curriculum and five-year courses are coming into use. Whether this tendency will result in extending the curriculum to five or six years in length or in eventually making the engineering colleges graduate institutions as some even now advocate remains to be seen.

No outline of American technical education would be complete without mention of the co-operative methods now in operation in many colleges whereby the student spends part of his time in practical work and part in study thus obtaining his practical training and theoretical work at the same time. Students in such courses may "earn as they learn" and contact with industry stimulates interest in theory. There is also an important group of polytechnical institutes offering instruction in technology somewhat below the level of the higher schools but of great importance. Pratt Institute in Brooklyn may be cited as an excellent illustration. It is possible that this type of school may be increased by certain tendencies in the state educational plans. The high schools tend more and more to prepare boys and girls specifically for life and to lay less accent on college preparation Many state educational departments are even now offering technical training in the high school grades If the tendency to create junior colleges, by adding two or more years to the high school curriculum, continues we may look for the introduction of technical training in such colleges equivalent in value at least to the first two years of the present college courses.

Technical education in the United States, it will be noted, is still growing and is still somewhat in a state of flux though its principal characteristics seem to be fairly well evaluated. In any case it is an entity that has grown up as an independent educational function and which in all probability must be developed along its present lines rather than through any radical readjustments. (D. S. K)

ENGLAND

In Great Britain, technical education (including commercial education [*q v*]) and adult education are the two main divisions of the system of continued education Adult education (*q.v*) differs from technical education in that it has no specific relation to vocational demands. Both technical and adult education had their origins in the industrial revolution of the nineteenth century, although it was not until the twentieth century that technical education began rapidly to take the place of the system of apprenticeship which dated back to the mediaeval craft guilds The first "mechanics' institute" in England and Wales was set up in London at the Birkbeck College in 1824 Similar institutes were rapidly established in other parts of the country; by 1841 there were over 200, and by 1860 there were 750, of which the majority were in the industrial towns of the Midlands and of Lancashire and Yorkshire The mechanics' institutes were mainly designed to give, at evening classes, scientific and technological instruction to workmen (*See* COMMERCIAL EDUCATION.)

Legislation.—The Great Exhibition of 1851 led to the formation of the Science and Art Department, and until 1879 the main income of the mechanics' institutes and "science and art" schools, some of which had been built under the Public Libraries Act, was derived from grants made by that department in respect of students successful at its annual examinations. The arrangements were criticised before the Royal Commission on Technical Education which heard evidence in 1882 and 1883. In 1879 the City and Guilds of London Institute began its support of technological instruction from funds placed at its disposal by the City Livery Companies. During the last forty years the Companies have given about £2,000,000 for secondary and technical educational purposes.

The City of London Parochial Charities Act, 1883, fostered the development of polytechnic institutions in London (*q.v.*). In 1889, the Technical Instruction Act empowered county councils and county borough councils to aid technical education and in 1891 the Local Taxation (Customs and Excise) Act provided these bodies with funds (colloquially known as "whiskey money") for that purpose, although some of this was afterwards diverted for secondary education (*q.v.*). In 1899 the Science and Art Department and the Education Department of the Privy Council were merged into one national department called the Board of Education. The Education Act of 1902, which was applied to London in 1903, made the county councils and the county borough councils responsible for supplying or aiding the supply of technical education, and these powers enlarged by the Education Act of 1918 were subsequently incorporated in the Education (Consolidation) Act of 1921.

Municipal Technical Schools.—From 1889 to 1899 there was great activity in the provision of sites and buildings for science, art and technology. In London two more polytechnic institutions were established, and the London County Council inaugurated its policy of "maintained" technical schools, that is, schools supported entirely by the local education authority. Among such schools were the technical institutes at Shoreditch, Westminster, Wandsworth and Norwood, the Central School of Arts and Crafts, the Camberwell School of Arts and Crafts, the School of Photo-Engraving and Lithography, the School of Building at Brixton, and the School of Engineering and Navigation at Poplar. Many of the great towns, such as Birmingham, Blackburn, Brighton, Halifax, Huddersfield, Hull, Leicester, Loughborough, Manchester, Oldham, Rochdale, Salford and West Ham, provided new or enlarged technical schools. In 1898–9, £866,063 was spent by public authorities on technical education in England and Wales, apart from the amounts raised by loan, and nine out of ten of the county councils and the county borough councils had voted grants in aid.

The Education Act of 1902, by adding the provision of secondary and university education to the responsibilities of the local education authorities, slowed down the rapid developments in technical education which had previously occurred. London enlarged five of the polytechnics and five technical schools, and built new schools at Hammersmith and Lambeth, while building work was also done at twenty-one other large towns.

The most characteristic development was the establishment in 1907 of the Bloomsbury Trade School for Girls, the first trade school to be provided in the English educational machinery on self-contained premises and organised on independent lines. Other trade schools were founded in London, Middlesex and elsewhere. Fostered by a system of trade scholarships awarded to girls at the age of thirteen, they have achieved a notable success with employers and have created opportunities for skilled employment for girls. In 1913 full time day technical classes for boys and girls, which were definitely pre-apprenticeship or trade schools, became eligible for state aid under regulations for "junior technical schools."

Under municipal auspices all the large towns of Great Britain have established technical schools of the first rank, and these are effectively organised to meet the requirements of local industries. Throughout the country, however, both industry and commerce had attained a high development before the support of technical education became a duty of the education authorities.

Statistics.—Since 1919 technological instruction in universities and constituent colleges has ceased to be aidable by the Board of Education, University Grants Committee now undertaking this function. The number of students in England and Wales under technical instruction, as defined by the regulations of the Board of Education, was 781,034 in 1926–27. The public expenditure on technical education is about £3,000,000 annually. The technical and continuation schools included 145 junior schools, 54 senior full-time courses, 134 technical day classes, 237 senior art schools, 67 day continuation schools and 4,911 evening institutes and evening courses in colleges. About 19 persons for each 1,000 of population were under technical instruction and other forms of continued education as compared with 10 per 1,000 under instruction at secondary schools. In London nearly 250,000 students attend day and evening continuation schools of all kinds, equivalent to about 40 persons per 1,000 of population; 37 evening institutes and 21 technical schools each have over one thousand students; the number of female students is slightly in excess of the number of male students, while the number of adults, that is persons over eighteen years old, is the same as the number of young persons between 14 and 18 years of age.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

An important development of technical education was the founding in 1907 of the Imperial College of Science and Technology. A Royal Charter merged the Royal College of Science, the Royal School of Mines, and the City and Guilds (Engineering) College, institutions at South Kensington, which had been established at different times during the nineteenth century, into a federation under the name of the Imperial College of Science and Technology, for the specific purpose of the highest education and research in science, especially in its application to industry. (*See* EDUCATION AND INDUSTRY, ENGINEERING EDUCATION.) Buildings of the Imperial College in 1928 numbered seven. The governing body is constituted from representatives appointed by the Crown, the Board of Education, the University of London, the London County Council, the City and Guilds of London Institute, of professional bodies and of the Dominions Overseas.

The College is mainly supported by grants from public authorities and industrial organisations. For the period 1925–29 the London County Council granted £27,000 yearly, and this was voted on the assumption that the Treasury, through the University Grants Committee, would vote at least three times that amount. The Rubber Growers' Association raised a fund of £30,000 for development purposes in 1921, and the Air Ministry, and the Ministry of Agriculture and Fisheries pay contributions for research carried out on their behalf. Other contributors to its financial resources include the Empire Cotton Growing Association and the Goldsmiths' and Clothmakers' guilds. About thirty per cent of the students are now engaged in post-graduate work and research. In the north of England the Manchester College of Technology, an institution of university rank, provides facilities on somewhat similar lines, while the Shirley Institute conducts very important research for the textile industry. (*See* also UNIVERSITIES.)

SCOTLAND

Modern technical education in Scotland had its origin in the founding of Anderson's University in Glasgow at the close of the eighteenth century. Dr. George Birkbeck founded the Mechanics' Institution in 1823, and these two foundations have since become the Royal Technical College, Glasgow.

A Technical Schools Act was passed in 1887. In 1893, the first "Scotch Code of Regulations for Evening Schools" appeared, and this led to a consolidation of effort and the development of a homogeneous system of continuation class instruction. In 1897, the Education Department of Scotland was separated from that of England, and the administration of science and art grants was transferred to a Scottish education department.

Section 87 of the Code of 1901 constituted the technical colleges and schools of art in Edinburgh, Glasgow, Dundee and Aberdeen, and certain other colleges as special institutions ("Central Institutions"). These institutions were relieved of their more elementary teaching and received subsidies which enabled them to develop higher studies.

Some of the central institutions such as the Heriot-Watt College, Edinburgh, the Royal Technical College, Aberdeen, and Robert Gordon's Technical College, Aberdeen, are of University rank, co-operating closely with the corresponding universities in the provision of degree courses. In most of the districts the general continuation class system is linked up with the central institutions, subjects and courses are correlated, and bursaries are available to provide financial aid to the poor student.

The Education (Scotland) Act, 1908, provided that "it shall be the duty of a School Board to make suitable provision of

continuation classes for the further instruction of young persons above the age of 14 years with reference to the craft and industries practised in the district. . . ." In 1923 and 1926, regulations were introduced which strengthened the tie between day school and continuation class education, and adapted the latter to changes of industrial conditions and educational requirements.

NORTHERN IRELAND

Technical education in Northern Ireland is mainly derived from the Department of Agriculture and Technical Instruction which was set up in Dublin by an Act of 1899 Under this Act county boroughs, urban districts and counties which struck a special rate for the purpose were enabled to receive grants for approved schemes of technical instruction. The Northern Ireland Education Act of 1923 made the City Councils of Belfast and Londonderry and the six county councils the education authorities for their own areas. Twenty-five technical schools have been transferred to the County Education Authorities The special rate for technical education disappeared as a rule and the general rate for education took its place In 1926–27, 23,704 students were in attendance at technical schools and a system of junior technical and day commercial schools had been inaugurated. A trade scholarship scheme is in operation and apprentice scholarship courses are held

IRISH FREE STATE

The Department of Education set up in 1924 took over the functions of the Technical Instruction Branch of the Department of Agriculture and Technical Instruction established by the Agricultural Technical Instruction (Ireland) Act, 1899. Technical instruction schemes are now all under the management of local Statutory Committees, State grants being contingent on the raising of a local contribution from the rates. The chief technical schools are at Dublin, Cork, Galway, Limerick, Rathmines, Tralee, Waterford. In 1927, the total number of students enrolled in classes in technical schools was 22,718, while 35,437 students (mainly evening students) enrolled in classes conducted under county schemes of technical instruction elsewhere than in established technical schools. Instruction in the Irish language forms the largest portion of the work done in the county schemes The Local Government (Temporary Provisions) Act empowered councils to strike a rate not exceeding 1d. in the £ of rateable valuation for instruction in Irish, the administration being placed in the hands of the committees of technical instruction. In preparation for employment in trades, there are ten trades preparatory schools, the largest of which is at Cork The Report of the Commission on Technical Education, which was issued in 1927, referred to the meagreness of technical instruction, particularly in rural areas.

BRITISH DOMINIONS OVERSEAS

Australia.—The expenditure on technical education for Australia is comparatively small. In 1925, the total expenditure on maintenance was £599,077 and on buildings £138,161 The expenditure on maintenance amounted to 2s. per head of the population, as compared with 27s 10d per head for primary and secondary education. New South Wales adopted a co-ordinated scheme of technical education in 1913.

In Victoria a Royal Commission was appointed in 1899, and in 1910 the control of the schools passed from local councils to the Education Department. In Queensland, under the Technical Instruction Act of 1908 and an amending act of 1918, the State was empowered to assume the control of technical institutions, and this power has been steadily exercised. The policy of combining technical colleges with high schools in the country centres has proved successful in some States, and peripatetic schools of Domestic Science and Manual Training, housed in specially fitted railway cars, visit the smaller towns. In four States, systems of apprenticeship operated by commissions are linked up with industry.

A Director of Technical Education for South Australia was appointed in 1916, and in 1921 further steps were taken, by proclamation, to develop the technical education of apprentices. All technical schools in Western Australia are under the control of the Education Department, which also employs a director of technical education. In Tasmania, a trained technologist was appointed as organiser in 1917, and a Technical Education Branch established in 1918.

New Zealand.—Technical schools are well distributed throughout New Zealand. Any young person between 14 and 17 years of age who is not otherwise receiving a suitable education may be compelled to attend a technical or continuation class. Although not yet in full operation, these compulsory powers have been applied to a number of school districts.

Canada.—Technical education in Canada is now organised in accordance with the Dominion Technical Education Act of 1919 In 1926, the number of municipalities providing day and evening schools was 238, the teachers employed numbered 3,478 and the number of students enrolled was 88,961. The Federal grants amounted to nearly one million dollars, the grants to local boards to nearly two million dollars.

South Africa.—As the outcome of a conference at Durban in 1924, vocational education in South Africa was transferred from Provincial to Union control. Under the Union Education Department there were in 1926–27 seven technical colleges, seventeen part-time technical schools and thirteen departmental trades, housecraft and agricultural schools. These schools were attended by 16,364 students. The largest technical schools are the Witwatersrand Technical Institute, the Cape Technical College, Cape Town, and the Natal and Pretoria Technical Colleges Technical and commercial examinations are regularly held under the supervision of the Union Department of Education with the object of stimulating vocational education in combination with or in continuation of the ordinary school curriculum.

India.—In recent years there has been a demand in India for more facilities for technical education In 1925 there were 556 technical institutes, amongst the most notable being the Sydenham College of Commerce at Bombay, the Technological Institute at Cawnpore, and the Technical Institute at Jamshedpur, the centre of the iron industry. (For the Dominions *see* also UNIVERSITIES)

FRANCE

In France the arrangements for technical and commercial education were re-organised by the *Loi Astier* of 1919, and by a decree of 1922 the organisations, public and private, interested in vocational guidance were placed under an Under-Secretary of State for Technical Education. Each department into which France is divided has a committee for technical instruction and the majority of them have offices for vocational guidance. Apprentices and young employees under eighteen years of age can, in districts specified by Ministerial Order, be compelled to attend *cours professionels* There has been in recent years a considerable increase in the number of full-time schools of industrial and commercial education (*écoles pratiques de commerce et d'industrie et écoles de métiers*). In 1926, technical and vocational schools were attended by 311,753 students; the number of vocational schools in 1924 was 1,085 as compared with 143 in 1892. Among the most famous schools of the first rank are the École Centrale (Marine Engineering), the École Nationale des Arts et Métiers at Châlons, the École des Mines and École des Ponts et Chaussées. In all there are 6 national schools of arts and crafts, 5 national vocational schools, 114 practical schools of commerce and industry, 30 courses in household arts for girls, and about 650 compulsory vocational courses in 82 departments and 332 communes. In Paris have been organised schools of industrial heating, for foundry work, milling, dietetics, an institute for sanitation and hygiene in industries, an optical institute, and, at Sèvres, an institute of ceramics. A law of 1918 authorised the development of agricultural education, and by 1924, 32 practical schools of agriculture had been formed while meetings for the dissemination of agricultural knowledge were being conducted under expert guidance.

GERMANY

The characteristic aim of technical education in Germany has

been to build up a great industrial nation by systematic training of all grades, from leaders to workmen. The Technische Hochschule is an institution of university type, providing facilities for scientific research and degrees in engineering. In 1926 the commercial college at Berlin began to confer the doctorate in economics. The Charlottenburg Institution in Berlin, which was completed in 1884 at a cost of about £450,000, includes departments for the highest specialised instruction in nearly all technological subjects. The success of this institution was one of the factors which led to the establishment in London of the Imperial College of Science and Technology. Although the Federal Continuation School Law is, for financial reasons, largely inoperative, Saxony, Thuringia, Anhalt, Brunswick and Hamburg have introduced compulsory attendance for both sexes; other states require it of boys for skilled trades. Since the war, evening classes have become more numerous, particularly in connection with the continuation and engineering schools. "The contrast between the fragmentary beginnings of the system of continuation schools which this country (*i.e.*, Great Britain) can show," reported in 1927 Sir Arthur Balfour's Committee on Industry and Trade—*Factors in Industrial and Commercial Efficiency*—"and the wide and rapidly extending provision in Germany is a fact of very great importance."

The city of Berlin maintains two schools of arts and crafts. In Leipzig there is an arts and crafts section of the City High School and of the Technical Academy, to the latter of which has been added a school of mechanics. Bavaria has two state schools of applied art, one at Munich and the other at Nuremberg. In 1921–22, the German Republic had 11,747 vocational full-time and continuation schools with 1,013,019 male and 329,475 female students.

OTHER COUNTRIES

Austria.—In Austria, the first arts and crafts schools were founded in the nineteenth century; to-day the Republic possesses a variety of such schools. At Vienna are the Polytechnic School and the Graphic School and Experimental Institute. Included in the federal trade schools are higher sections for training students to qualify as owners or directors of industrial establishments in such occupations as the building trades, engineering, and the chemical and textile industries. Successful attendance reduces the period of apprenticeship, while students who pass out with honours are entitled to attend the Austrian Technical University or the College for World Commerce. There are also two-year and one-year educational establishments for women's trades, and special schools for weaving and textiles, locksmiths, watchmaking, electrotechnics, woodwork, metalwork and stonework, ceramics and decorative painting. In 1923–24 there were 148 special vocational schools.

Italy.—Technical education in Italy is regulated by the Ministry of National Economy and by decree of 1923. Vocational training is given in people's schools for workers or preparatory schools, in industrial or apprenticeship schools, at courses for journeymen for developing the working capacity of apprentices or workers, in industrial institutes for training future managing and technical staff in factories, industrial workshops and technical laboratories, and at experimental establishments for furthering technical progress in industry by means of study, research, analysis and inquiries.

In 1921–22, the number of industrial schools (apprenticeship schools, vocational schools for girls, and special schools) was 174, of which 93 were royal (*i.e.*, set up by royal decree) and 81 free (*i.e.*, set up by local authorities or private organizations), and the number of pupils was 28,091. There were also 282 (18 royal and 264 free) part-time schools with 26,292 pupils.

The most important of the industrial institutes is the Institute for Vocational Education at Rome. It has two sections, one for the training of expert mechanics and electricians, and the other for training experts in the building industry.

Scandinavia.—In Sweden, technical schools are of comparatively recent origin; it was not until 1918 that they were brought together into a systematic organization. In 1920, a Central Institute for Training Vocational Teachers was established in Stockholm. Technical instruction is now provided at full-time workshop schools, apprenticeship schools, trade schools, and schools of commerce and domestic economy. Technical trade schools and technical gymnasiums are, for the most part, maintained by the State, although there are private commercial gymnasiums. In Norway, continuation schools have been established both in cities and country districts.

Holland.—There are many trade and vocational schools in Holland, where most of the chief industries have higher and lower technical schools. There were in 1925, 12 technical high schools and numerous other technical, trade and agricultural schools.

Switzerland.—In Switzerland, continuation schools are, as a rule, organized by the communes, although the state has made them compulsory in many of the cantons. Vocational schools, whether municipal or cantonal, are subsidised by the Confederation. The country also possesses a federal "Polytechnicum" at Zürich, which is of university rank. The national industries, also, have stimulated the establishment of schools for the industrial arts, while vocational guidance is being developed by the *Association Suisse des Conseils d'Apprentissage*. Zurich has a bureau of vocational guidance, and a beginning has been made with psychological tests at the Institut J. J. Rousseau in Geneva and at the Psychotechnisches Institut in Zürich. Efforts are also being made to develop continuation courses in agriculture, in 1926, there were 22 agricultural schools.

Czechoslovakia.—The organization of continuation schools in Czechoslovakia is fixed by orders of the State, based upon a law of 1919. Every trade apprentice is required to attend a continuation school and to remain in attendance for eight to fourteen hours weekly. Specialised technical instruction is provided for groups of at least seven students in a general trade continuation school. Professional continuation schools are, however, steadily replacing general trade schools. In 1925–26 there were 2,615 continuation schools attended by 203,227 pupils, of whom 49,631 were girls.

Estonia.—In Estonia, trade schools were constituted by a law of 1925. Vocational training in Finland is provided in commercial, agricultural, technical and trade schools. Lower and higher technical schools are organized in Poland, as well as artisans' schools, evening continuation, commercial and agricultural schools. In Latvia, the number of students at the technical and commercial middle schools increased from 285 in 1919–20 to 2,610 in 1924–25. A Royal Decree of 1923 determined the organization of technical institutes in Italy; other vocational schools are organized by the Ministry of National Economy.

Japan.—Technical education in Japan is for the most part provided at government and public institutions. In the category of technical schools are included also agricultural schools, commercial schools, nautical schools, fishery schools. Generally speaking, students admitted must be above twelve years of age. Industrial schools are provided for children of superior attainments, and technical continuation schools for children from elementary schools who are engaged in industry. In 1924, there were 15,528 public and 193 private technical schools, staffed by 17,620 teachers and attended by 1,206,098 pupils. Most of the schools were junior continuation schools. The higher technical schools, of which there were 35 under the direct control of the Department of Education, provide advanced studies in the same subjects as are found in the curricula of European institutions. (*See* also, for the above countries, UNIVERSITIES.)

(G. H. GA.)

TECHNIQUE IN ART. Technique is the manner of artistic execution, the performance or method of manipulation in any art, but as to just how inclusive this definition should be regarded is a question. Certain authorities claim that technique is distinct from any consideration of general effect or expression, while others assign to it the meaning of the doctrine of the arts in general. The first conception might be called "Mechanical technique" and the latter "Technique principle"

In this work the mechanical technique in each art is treated under each individual heading as the mechanical techniques vary considerably in detail—that of the sculptor being different from that of the wood-engraver, and that of the painter differing from that of the etcher. This article will therefore deal only with the broader conception of the definition—the technique principle, or those underlying rules which are found to be true in the practice of all of the arts.

It may be said that such a discussion falls within the field of aesthetics, but the difference lies in the fact that while aesthetics is a metaphysical discussion of man's conception of beauty, the technique principle is a discussion of how to obtain beauty or human appeal in a work of art The one is philosophy and the other is a practical science based upon observation and reason The one has to do with a discussion of the result, while the other shows how this result, indescribable as it sometimes may seem, can be obtained The means whereby man can appeal to man in the creation of beauty, modern science has analyzed to a remarkable degree, and just as Henri Bergson in *L'Evolution Créatrice* destroyed the old philosophical conception of negation by the application of modern psychology, so have many of the old principles of philosophic aesthetics been destroyed by like methods The modern artist must not only have mastered rules of anatomy and perspective through study such as that of many of the old masters over the dissection tables, and of mathematics, but must inquire into the psychological reactions caused by light or by various colours, the chemical action of his paints, the analyses of movement as revealed by the motion picture camera and many other phases of modern scientific development, and therefore the old conception of the artist as an intuitive being dreaming his way through life and seizing now and then with the aid of a divine fire a dream which he in some inexplicable way makes tangible and durable for his fellowmen, must be cast aside The artist may dream, as the man of science or the inventor dreams of the creation of some remarkable work, but the work itself is a painstaking process of reason and the result may often be quite different from the cloudy original blur which was the first conception. The study of the subconscious has done much to explain intuition, and the modern man has learned to place less faith in the vision of glory which used to move his forefathers, for he realizes that these immediate apprehensions of "truth" are topsy-turvy mirages of what may or may not be proved true by the searchlight of modern scientific reason The modern artist is first of all a modern man in every sense abreast of the times, and, as an indispensable prerequisite, every artist must first learn to appeal to his fellowmen. (*See* AESTHETICS)

Although the modern artist is perhaps more awake to the necessity of adopting this viewpoint, because of the recent marvelous developments of science, nevertheless many of the great masters of the past have also expressed themselves clearly along the same lines. Leonardo da Vinci has said "Thou, O God dost sell unto us all good things at the price of labour" and throughout all of his writings Da Vinci has laid stress upon reasonable labour rather than trust to inspiration. Rodin said, "Nothing will take the place of persevering study—to it alone the secret of life delivers itself." Turner stated that he had no secret but hard work, and Pliny relates that the secret of Apelles was due to constant practice. Hundreds of other examples might be quoted, but it is sufficient to say that throughout the ages both in the Far East, where a great painter has been quoted as saying, "Man cannot call himself an artist until he has painted 10,000 pictures," to the western schools represented by such quotations as above, artists in writing of their own work have laid great stress upon the labours of pure reason involved, while critics in writing of art (that field in which they have as a rule never practised) explain it on the grounds of a mysteriously intuitive and God-sent passion. Due to the critics, art has too long been considered a gift of the gods and artists who are usually contented to let the results of their labours speak for themselves have too long been misunderstood. Let us therefore examine a few of the processes of thought of which they make use. (*See* PAINTING.)

Conception.—The original conception of a work of art or of an invention of any sort is usually largely intuitive, in that it may be said to reach out beyond the regular step by step procedure of pure reason. The possibility of such and such a thing often occurs suddenly after a long and arduous searching of the facts which may be more or less involved The mind grasping the trend in which the assembled facts seem to be leading will reason ahead of the yet unproved result and the inventor or artist may say to himself that if such and such could only be done the result would be desirable, and he then sets himself to obtain this result as he conceives it Thomas Edison must have said something of the sort to himself when he first made an electric wire glow in a vacuum and suddenly perhaps imagined the possibility of stringing these glowing bulbs along a street so that it might be illuminated by a current of electricity. The artist's conception is similar. He suddenly realizes that a certain grouping of figures under an illumination of a certain sort producing certain highlights and shades would give a magnificent effect for some cathedral mural decoration For years this general idea may be kept in the back of his mind until the opportunity offers itself and certain other relative conditions fall into line and make it possible for him to attempt its development.

His first step is often a preliminary sketch which is rough and undetailed and which is only a sort of notation aiding him to keep his general scheme in mind. He may then proceed to work out the details just as does an inventor. "Will such an arm if lifted procure a more rhythmical line in the composition?" "Would such a raising of the arm be natural to the figure?" "Is this shadow to be darker than that or would it be too much of a spot and should it glow with a diffused light reflected from some nearby surface?" "What surface could be brought to use in the reflecting of this light?" and similar questions occur in his mind and must be solved logically and reasonably

During the solution of these questions he may make innumerable sketches or notes just as the scientist takes notes during the various steps of experimentation in his laboratory, and it is through the assembling of the more important of these various considerations that finally the work of art is actually conceived and constructed

Expression of Material.—Among the fundamental considerations of every great artist is that of the appropriate expression of the material in which his work is to be executed. Watercolours should not be handled in such a way as to resemble oil; brass should not be finished to imitate bronze; and the reason for this is that people who may never have consciously thought about art have learned to associate certain characteristics with each substance they find about them. There is a feeling of disconcerting surprise when these characteristics are not evidenced, like the sensation when one touches one of the metal desks made to appear so perfectly like wood One may never have considered consciously the warmth of wood though subconsciously one's mind has taken note of it. This surprise whether to the sense of touch or sight is always misleading and is usually ruinous to the effect of what might otherwise be an excellent work of art. We know for instance that iron is so strong that man cannot bend a slender rod of it and if we are confronted therefore with an iron garden gate made of thick and uselessly heavy pieces of metal we mistrust that it is iron and suspect that it may be lead or some other substance. Tapestry lends itself to a certain sort of design which can be better expressed in its weave than it can in a mosaic or fresco. (*See* WATER COLOUR PAINTING, OIL PAINTING, TAPESTRY, etc.)

The faculty for properly expressing the medium, avoiding its limitations and taking advantage of its possibilities, is one not arrived at by intuition but by careful research and practice, so that the artist sometimes learns almost *to think* in the medium

which he has studied. Thus a painter may actually learn to see a landscape in brush strokes, or a composer of music associate at once a certain section of the score with the tone quality of a certain instrument or group of instruments.

The Expression of the Tool.—Fully as important as the consideration of material is that of the characteristics of the tjantjing tools with which it is to be worked. The brush of sable, the tjantjing, the etching point, the chisel, the wheel of the gem cutter or even the fingers of the sculptor modelling in clay, will each make a certain cut, mark or impression which must be studied in relationship to the material. (*See* ART, FAR EASTERN METHODS.) It is unpleasant to see clay carved with a sharp instrument as though it were wood, or stone, or to behold what appears to be a woodblock print and find that it has been painted with the brush.

Not only must the mark of the tool be considered in relationship to the material but it is capable if properly handled of a beauty in itself comparable to the single note drawn by a master hand from a fine violin. Look at the line drawn upon a piece of paper by a master draftsman. Is it not similar to the violin note with its gradations of shade and its sweeping curve? The expression of beauty in a masterful handling of the tool so that each note is pleasing was a joy to the ancient artist and he would often spend years acquiring this deftness which many modern artists have been fooled into thinking is unnecessary because of the stressing of originality and spontaneity in art training.

But even this carelessness, deplorable as it is, is more forgivable than the custom of the last century of deliberately faking tool marks. Wood cut by machines to give the appearance of being hand-hewn and iron artistically dented to appear hand-forged had come to be almost universally accepted though nothing could show greater evidence of dishonesty of technique and bad taste.

Style.—No two artists can paint the same face or the same landscape in the same way any more than two business men can sign their names in the same way. Neither the style nor the personality of the artist need be thought about and certainly should not be artificially cultivated. However, if one is to permit his style to grow he must not hamper it by the slavish copy of some other artist's personal style. He may to advantage copy works of art again and again, but should do so simply to broaden his outlook, as a writer may read the books of many other writers.

The present day stressing of originality in art teaching is responsible for much of the worst of our modern art. Technique is all that can be taught. Style and originality of real value can only come after the artist's experiences both in life and in art have broadened and enriched his personality, for the artist cannot express a personality until he has one and, if he has one, he cannot help but express it. (*See* THEATRE; DIRECTION AND ACTING.)

Suitability.—Suitability to surroundings is an element often lacking in the art of to-day due to a strange occurrence which took place during the decadence of the Renaissance. It is interesting to know that during the best periods of art the distinction between fine arts and applied art was not clear. In Egypt it was unknown. In Greece sculptors did as masterful work for the pediment of a building as for a pedestal. In the Orient the distinction has not existed for thousands of years and a porcelain vase or a piece of lacquer may be regarded just as highly as a painting or a piece of sculpture.

Michelangelo and Cellini did not recognize the distinction and were as proud of what might be called their craftsmanship or works of applied art as they were of those which could be labelled "fine art." Both were craftsmen at heart and unspoiled by what occurred immediately following their times.

"Fine Arts" as a term came into use meaning painting, sculpture, music and poetry, with sometimes the inclusion of architecture or those arts which exist for the pleasurable qualities alone and apart from any utilitarian consideration, but "fine arts" came to be thought of as of greater importance than applied arts for, if some of the arts are termed fine, the implication is that the other arts are less fine, and the result of this usage was that people came to consider art which had no application superior to art which was applied. They argued "Yes, that is beautiful for its purpose, but this is finer for the very reason that it has no purpose other than that of being beautiful." (*See* FINE ARTS.)

The result was a tendency toward less and less consideration of the principles of application of art. Sculptors preferred to work in their studios than to co-operate with architects. Great painters ceased to do murals and worked upon easel pictures. Recently, however, there has occurred a happy revolt against this attitude, more especially in America because it was found there that applied art paid better than fine art. In other words the public had judged and with the disappearance of the marble pedestal and whatnot from the Victorian interior, there was also a disappearance of bibelots and the old time easel paintings so that the artist is now confronted with the necessity of studying the antique as did the great masters and the principles of proper spacing, and must adopt the more modest attitude that his work, in order to be successful, must be considered as only part of an ensemble. (*See* SCULPTURE; GARDEN; LAMPS.)

Time Consideration.—Works of art differ from works of nature in that they cannot reproduce themselves and should therefore express in some way their vulnerability before the onslaughts of time. Part of the appeal of the antique is due to the fact that it is bowing with such grace and such pathetic dignity and beautiful spirit before the inevitable. The patina of an old bronze or the iridescence of an ancient glass vase is the touch of great Nature bidding it return to its original state. (*See* BRONZE AND GLASS.)

Structure.—Structure itself may be considered but an admission of the necessity for fortification against time and when proper structure is not observed one can foresee at a glance the indignity of the final defeat. Some works of art like some people grow more beautiful with age, for the scars of years serve only the more clearly to prove the sturdiness within. It is wise therefore for the artist to think of the final conditions of ruin of his work and build it in such a manner that it will be beautiful as long as it is recognizable. (*See* IRON.)

Fragility.—If structure appeals to us because of its intelligent defence against time, fragility undoubtedly appeals because of its pitiful bravery, for just as we have regard for some men for their reasonable sanity we like others for their careless daring. It is this appeal which has undoubtedly been responsible for the preservance of some of the delicate glass which has been passed from hand to hand down through the ages. Each hand though perhaps calloused by the sword or plough, though made careless by wine and laughter has touched it with a certain amount of care because of the realization of its brave stand against time. (*See* GLASS.)

A most strange and interesting study is this element, time, and our accounting for it, for though we realize that in it lies ultimate destruction we anxiously look for its touch on many works of art, feeling a mistrust for those things which have not proven themselves against it. Sculptors finish their bronzes with artificially applied patina not for the purpose of faking antiquity but simply to satisfy the eye as the boy with a new pair of shoes will scuff them in the dirt to take off the newness. A round corner is more beautiful than a sharp new one. Old polished wood is more beautiful than new and a painting, a statue or a piece of furniture finds a pleasing richness as the years impose a modification of the exact statements of the artist's brush or chisel.

Such considerations as those few outlined above will give the reader an idea of what the artist is thinking about as his work proceeds, and an understanding as to why and how it is made to appeal to the mind of his public. Abstract beauty may exist, though the philosophers seem to have some difficulty in defining it, but some of the elements of beauty which appeal to man in a work of art can thus be analyzed, weighed and combined by the artist into a worthy result. (W. E. Cx.)

TECK, a ducal castle in the kingdom of Württemberg, immediately to the N. of the Swabian Jura and S. of the town of Kirchheim, crowning a ridge (2,544 ft.) of the same name. It was destroyed in the Peasants' War (1525).

The duchy of Teck was acquired early in the 11th century

by Berthold, count of Zähringen, whose great-grandson Albert, or Adalbert, styled himself duke of Teck. In 1381 it passed both by conquest and purchase to Württemberg The title, which had lapsed with the extinction of the Zahringen line in 1439, was revived in 1495 by the German King Maximilian I, who bestowed it upon the dukes of Wurttemberg The dignity was renounced by Duke Frederick William Charles upon his elevation to the rank of king in 1806. In 1863 the title "prince of Teck" was conferred by King William I. of Wurttemberg upon the children of Duke Alexander of Wurttemberg (1804–1885) by his morganatic marriage with Claudine, countess Rhédey, ennobled as countess of Hohenstein; in 1871 Prince Francis, the eldest son of Duke Alexander, was created duke of Teck His eldest son Adolphus (b. 1868) was in 1910 the holder of the title.

TECUCI, the capital of the Tecuci department of Rumania, picturesquely situated among wooded hills on the right bank of the river Bêrlad, and at the junction of railways from Bacau, Bêrlad, and Galatz Pop. 21,000. Tecuci has a large transit trade in grain, timber, cattle and horses, between northern and eastern Moldavia and the Danubian ports.

TECUMSEH, TECUMTHE or **TECUMTHA** (*c.* 1768–1813), American Shawnee chief, was born probably in the old Shawnee village of Piqua, near the site of Springfield (O), between 1768 and 1780. While still a youth he took part in attacks on settlers passing down the Ohio river and in widely extended hunting expeditions or predatory forays to the west and south; and he served in the Indian wars preceding the Treaty of Greenville in 1795. His eloquence and his self-control made him a leader in conferences between the Indians and whites as early as 1800, and when in 1804 and 1805 the Indians of the North-west became aroused by a series of treaties calling for new cessions of their territory and by the prospect of war between Great Britain and the United States, the opportunity was presented to Tecumseh and to his brother Tenskwatawa (*i.e*, the Open Door), popularly called "the Prophet," to put into operation a scheme which followed the ambitious dream of Pontiac. With some scattered Shawnee clans as a nucleus, the brothers proceeded to organize, first near Greenville, Ohio, and later on the White and Tippecanoe rivers in Indiana, "the Prophet's town," which was based on a sort of Communism and was apparently devoted to industry and sobriety, but their actual plan was to combine all of the Indians from Canada to Florida in a great democratic confederacy to resist the encroachment of the whites Tribal organizations were to be disregarded, but all warriors were to be represented at periodical assemblages where matters of interest to all Indians were to be definitely decided. The twofold influence that was to dominate this league was the eloquence and political ingenuity of Tecumseh and the superstitious reverence aroused by "the Prophet." This programme alarmed the whites along the north-western border. In the course of the next three years Governor William Henry Harrison of Indiana held interviews with each of the brothers, and during one of these, at Vincennes in 1810, the respective leaders narrowly avoided a hostile encounter. Nevertheless "the Prophet" and Tecumseh reiterated their determination to remain at peace with the United States if the recent cessions, including that of 1809 which deprived the Indians of their best hunting-ground, were given up and if no purchases were made thereafter without the consent of the tribes Harrison refused to consider this arrangement, and during Tecumseh's absence in the South, made a hostile move against "the Prophet's town" The latter ventured to meet him, but was defeated Nov. 7, 1811, in the famous battle of Tippecanoe, which broke the personal influence of "the Prophet" and largely destroyed the confederacy built up by Tecumseh.

Tecumseh still professed to be friendly toward the United States, probably because his British advisers were not ready to open hostilities, but a series of border outrages indicated that the fatal moment could not long be postponed. With the breaking out of the War of 1812 he was commissioned a brigadier-general in the British army and participated in the skirmishes which preceded General William Hull's surrender at Detroit. He took an active part in the sieges of Fort Meigs, where he displayed his usual clemency towards his prisoners. After the battle of Put-in-Bay, when Col Henry Proctor began to retreat from Malden, Tecumseh bitterly reproached him for his cowardice and finally forced him to join battle with Harrison on the Thames river Oct. 5, 1813 In this battle Tecumseh was killed. "The Prophet" remained with a small band of Shawnees and died west of the Mississippi in 1834. Like Pontiac, whom he doubtless imitated consciously, he had a wonderful eloquence and a power of organization rare among the Indians. He is depicted in many historical plays and novels.

Webster, ***Harrison's Administration of Indiana Territory*** (1907), also sketches in Don Seitz, ***Uncommon Americans*** (1925); and Frances M. Perry, ***Four American Indians*** (1904), designed for juvenile readers.

TEDDER, HENRY RICHARD (1850–1924), English writer and bibliographer, was born in South Kensington in 1850 He studied in England and in France and dedicated himself chiefly to bibliography and library administration. In 1873 he became librarian to Lord Acton and several years later librarian of the Athenaeum Club. In 1889 he was also appointed secretary of the club and held both offices until his resignation in 1922 He was one of the active promoters of the first international conference of librarians held in London in 1877, out of which grew the Library Association of the United Kingdom of which Tedder was first honorary secretary and, from 1889 until his death, treasurer. He was active in all the society's meetings and undertakings and contributed about 20 papers to its different publications. He was treasurer of the Royal Historical Society from 1904 until his death, secretary to the Herbert Spencer Trustees and editor of a continuation of Spencer's *Descriptive Sociology,* and a member of the Royal Commission on Public Records from 1910 to 1919 He wrote a number of articles for the *Encyclopædia Britannica,* 11th edition, and also for the *Dictionary of National Biography* and the *Dictionary of Political Economy.* He died on Aug 1, 1924.

TEDDER: *see* CULTIVATING MACHINERY.

TEDDINGTON, an urban district in the Spelthorne parliamentary division of Middlesex, England, close to the Thames, 13 m. W.S W. of St. Paul's cathedral, London, on the N London and S railways. Pop. (1921) 21,213. The district is residential and the town is a resort of visitors both to the river and to Bushey park, which lies immediately south. (*See* HAMPTON)

TE DEUM, opening words of the ancient Latin hymn *Te Deum laudamus* (We praise Thee O God), at one time believed to have been written by St. Ambrose of Milan and now generally ascribed to Nicetas, Bishop of Remesiana in Dacia. Its noble character speedily procured its incorporation in the liturgy of the Latin church while it has been set separately by countless composers as a hymn of thanksgiving for special occasions.

TEE, in golf a small conical mound made of damp earth on which the ball is placed before making the first drive for a hole. Sometimes an artificial tee, usually made of rubber or wood is used. In some games, such as quoits, horseshoes, and hobs, the tee is the mark toward which the player throws.

TEELE, RAY PALMER (1868–1927), American economist, was born in Fillmore county, Minnesota, on Oct. 22, 1868 He was educated at the University of Nebraska (M.A, 1899), and from 1899 until his death was economist of the U S. Department of Agriculture. In 1910–12 and 1919–21 he served as special agent of the Census Bureau in charge of irrigation. He made investigations and wrote a number of government reports on water rights and irrigation and also contributed numerous articles to periodicals on these subjects. He was the author of a large number of government bulletins including "Land Reclamation Policies in the United States" (Dept. of Agri., Bull. No 1257, 1924) and "The western farmer's water right" (Dept. of Agri., Bull. No. 913, 1920). He also wrote ***Irrigation in the United States*** (1915), and ***The Economics of Land Reclamation in the United States*** (1927). He died at Myton, Utah, on Sept. 1, 1927.

TEEMANT, JAAN (1872–), Estonian statesman, was educated in law at Petrograd University. He practised in Reval, but in 1905 associated himself with the revolutionary movement for which he was condemned to death by the Russian government. He escaped to Switzerland where he lived a number of years, but in time returned to Russia and served a sentence of one and one-half years' imprisonment. He then resumed his practice in Reval. After the 1917 revolution he took an active part in the establishment of the new Estonian government, was a member of the Constituent Assembly, 1919–20, and after 1920 of the Estonian Diet. He rose to power as a leader of the Agrarian party and in December, 1925, became prime minister.

TEES, a river of England, rising on the east side of Cross Fell, and traversing a valley about 85 m. in length to the North sea. In the earliest part of its course it forms the boundary between the counties of Westmorland and Durham. The head of the valley (upper portion known as Teesdale) is not without desolate grandeur, the hills, exceeding 2,500 ft. in height at some points, consisting of bleak moorland. A succession of falls or rapids, where the river traverses a series of hard, black basaltic rocks, is known as Caldron Snout; and from a point immediately below this to its mouth the Tees forms the boundary between Durham and Yorkshire almost without a break. The dale becomes bolder below Caldron Snout, and trees appear, contrasting with the broken rocks where the water dashes over High Force, one of the finest falls in England. The scenery becomes gentler but more picturesque as the river descends past Middleton-in-Teesdale (Durham), the terminus of a branch of the North-Eastern railway from Darlington. In this locality lead and iron-stone are worked. The town of Barnard Castle, Eggleston abbey, and Rokeby hall, well known through Sir Walter Scott's poem, are passed; and then the valley begins to open out, and the river meanders across the rich plain east and south of Darlington. The river now becomes an important commercial waterway, having on its banks the ports of Stocton-on-Tees, Thornaby-on-Tees and Middlesbrough, and forming an outlet for the rich iron-working district of Cleveland in the North Riding of Yorkshire. The drainage area is 708 square miles.

TEETH, the modified papillae or elevations of the mucous membrane of the mouth, impregnated with lime salts. Each tooth has a biting part or crown covered by enamel, a neck where the gum surrounds it, and one or more roots or fangs fitting into sockets (alveoli) in the jaw bone. For surgery of the teeth *see* DENTISTRY.

There are 32 permanent teeth in man, 16 in the upper and 16 in the lower jaw; they are also arranged in symmetrical sets of 8 teeth on each side. The upper and lower symmetrical sets of 8 will be described. The two teeth from the mid-line in front are "incisors" and have chisel-shaped crowns. The central incisor of the upper jaw is broader than any of the others, and bites against the central and lateral incisors of the lower jaw; the same want of exact adaptation continues throughout the series, so that every tooth in the upper jaw except the last molar bites against its corresponding tooth of the lower jaw and also against the tooth behind that.

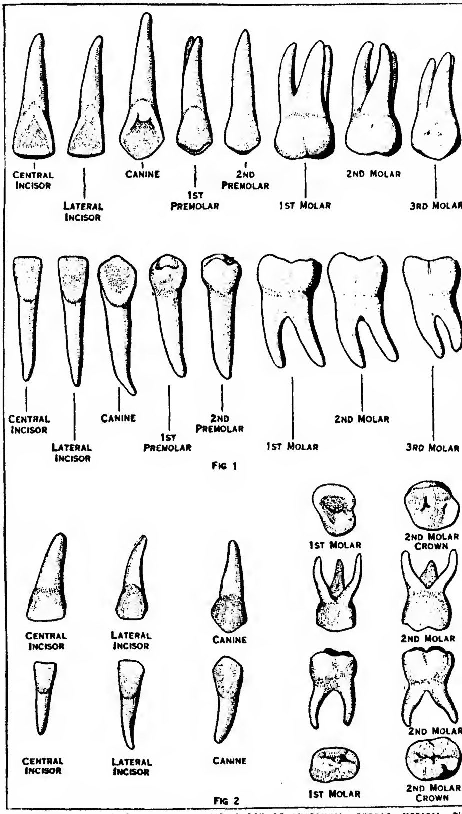
Next to the incisors comes the "canine (or eye) tooth," the crown of which is somewhat peg-shaped, while behind this are the two "premolars" or "bicuspids," whose crowns are flattened from before backward and bear two cusps, the larger of which is external. As a rule there is a single root, though sometimes in the first upper premolar it is double.

The three "molars" are placed behind the premolars, and the upper and lower sets can be easily distinguished because the upper have three roots while the lower have only two. The grinding surface of the crowns of the upper molars shows three or four cusps, while on the grinding surface of the lower molars four or five cusps are found.

Of the three molars the first is the largest, and the third, or wisdom tooth, the smallest, while the upper wisdom tooth is smaller than the lower.

In the "milk teeth" or temporary dentition of the child there are only 20 teeth, 10 in each jaw and 5 in each segment. They are two incisors, one canine and two so-called molars. These molars occupy the position which the permanent premolars later on take. The temporary teeth differ from the permanent in their smaller size, their whiter colour, the greater constriction of their necks, and in the fact that the roots of the molars are widely splayed.

The dates at which the milk teeth are cut are very variable. The lower central incisors come first between the sixth and ninth month, or even later; then come the central and lateral upper incisors; then the lower lateral incisors, followed closely by the first molars. After a rest of four or five months come the canines, while by about the end of the second year the second molars have appeared, and the milk dentition is complete. The milk teeth are cut in batches with resting intervals between.



FROM BIRMINGHAM IN CUNNINGHAM'S, "TEXTBOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

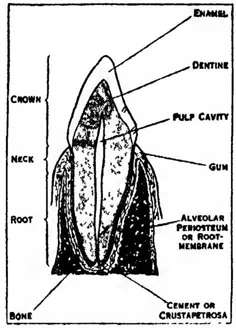
FIG. 1.—PERMANENT TEETH OF THE RIGHT SIDE, SHOWING INNER OR LINGUAL ASPECT. FIG. 2.—MILK TEETH OF THE LEFT SIDE

The first permanent tooth to be cut is the first molar, and this happens during or soon after the sixth year. It does not displace any of the milk teeth, but comes down behind the second milk molar. During the seventh year the central milk incisors fall out and their place is taken by the permanent ones; the shed teeth are mere shells of the crown, all the root having been absorbed.

The lateral incisors succeed their milk predecessors at about eight years old, the first premolar takes the place of the first temporary molar about nine, the second premolar that of the

second temporary molar about ten, the canine about eleven, while the second molar comes down behind the first about twelve The third molar, or wisdom tooth, usually appears between eighteen and twenty, but may be much later, indeed it is sometimes never cut at all, and when it is, it often does not come down to a level with the other teeth It is believed that man is gradually undergoing a suppression of his last molar teeth.

Histology.—In a vertical section the exposed part or crown is seen to be covered with enamel, which, microscopically, is composed of fine hexagonal prisms arranged at right angles to the surface of the tooth, and formed chiefly of calcium phosphate with small amounts of calcium carbonate, magnesium phosphate and calcium fluoride, but containing practically no organic matter. The enamel rests on the "dentine," of which hard yet elastic substance by far the greater part of the tooth is composed It is made of the same salts as the enamel, but contains in addition a good deal of organic matter and forms a structureless mass through which the fine "dentinal tubes" run from the pulp cavity to the periphery



FROM BIRMINGHAM IN CUNNINGHAM S, "TEXT BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 3.—VERTICAL SECTION OF CANINE TOOTH ILLUSTRATING ITS PARTS AND STRUCTURE

Surrounded by the dentine is the "pulp cavity," which is filled by the tooth pulp, a highly vascular and nervous mass of branched connective tissue cells, which, in a young tooth, has a layer of epithelial cells, the "odontoblasts," lying close against the wall of the cavity and forming new dentine Slender processes ("Tomes's fibrils") project from these cells into the dentinal tubes and are probably sensory. A nerve and artery enter the apex of the root of the tooth, but it is not understood how the nerve ends.

Surrounding the dentine where it is not covered by enamel is the "cement" or "crusta petrosa," a thin layer of bone which is only separated from the bony socket by the alveolar periosteum.

Embryology.—The lip is marked off in the mouth by a "lip groove," which, in the case of the lower jaw, grows obliquely downward and backward, and the mass of ectodermal cells bounding it penetrates for some distance into the surrounding mesoderm below the bottom of the groove. This is known as the "tooth band"

On the under surface of this oblique tooth band (still taking the lower jaw), and close to its edge, appear ten thickenings, below each of which the mesoderm rises up into a "dental papilla," and so moulds the thickening into a cap for itself—the "enamel organ." The superficial cells of the dental papilla become the "odontoblasts" and manufacture the dentine, while those cells of the cap (enamel organ) which are on its concave surface and therefore nearest the dental papilla are called "ameloblasts," and form the enamel The cutting or grinding part of the tooth is first formed, and the crown gradually closes round the dental papilla, so that at last, when the root is formed, the central part of the papilla remains as the pulp cavity surrounded by dentine except at the apex of the root. The roots, however, are formed slowly, and as a rule are not complete until some time after the tooth is cut. The mesoblastic connective tissue surrounding the developing tooth becomes condensed into a fibrous bag called the tooth-sac, and round this the lower jaw grows to form the alveolus. The crusta petrosa covering the root is developed from the tooth-sac. Hence of the various structures which make up a tooth, the enamel is derived from the ectoderm, while the dentine, pulp and crusta petrosa or cement are mesodermal.

Comparative Anatomy.—The details of the teeth vary so greatly in different animals, and, on account of their being the most durable tissues of the body, are so important for classificatory purposes, that they are dealt with freely in the various zoological articles. All that can be done here is to give a broad general survey, taking the details of man's dentition as a point of departure.

In some fishes the teeth are continuous over the edges of the jaws with the scales on the surface of the body, and there is no doubt that teeth should be regarded as modified scales which have migrated into the mouth.

In the Cyclostomata (lampreys and hags) the teeth are horny cones, but beneath them there are papillae of the mesoderm covered with ectoderm which resemble the dental papillae and enamel organs although no calcification occurs except in Bdellostoma. In the Elasmobranchii (cartilaginous fishes) the teeth are arranged in several rows, and as those of the front row fall out the hinder row take their place; sometimes they are triangular and very sharp as in the sharks, sometimes flattened and arranged like a pavement for crushing as in rays. These teeth only represent the crowns of man's teeth, and they are not embedded in sockets except the teeth in the saw of the saw-fish (Pristis), moreover the dentine of which they are largely composed resembles bone and fills up the whole pulp cavity. From its structure it is known as *osteodentine.*

In the Teleostomi (teleostean and ganoid fishes) there is great variability; sometimes, as in the sturgeon, there are no teeth at all, while in others every bone bounding the mouth, including the branchial arches, bears teeth As an example of a very full tooth armature the pike's mouth and pharynx may be instanced. Both in the pike and the hake hinged teeth occur; these bend backward during the passage of prey down the throat, but are re-erected by elastic ligaments As a rule, the dentine of the Teleostomi is osteodentine, but sometimes, as in the hake, it is vascular and is known as vasodentine.

In the Amphibia teeth are not so numerous as in the fishes, though like them they are not confined to the jaws, since vomerine teeth are very constant. The toad is edentulous, while the frog has no teeth in the lower jaw An extinct order of tailed amphibians, the Stegocephali, are often called labyrinthodonts on account of the complex way in which the enamel is involuted into the interior of the teeth

In the Reptilia various arrangements of the teeth are found In the Chelonia (turtles) there are no teeth, although the ectodermal ingrowth (dental band) from which they are developed in other animals is present in the embryo. The place of the teeth in these reptiles is taken by horny jaw-cases

In the Ophidia the non-poisonous snakes have two rows of teeth in the upper jaw, one on the maxillae and another on the palatine and pterygoid bones, while in the lower jaw there is only one row. These teeth are sharp pegs anchylosed to the bones and so strongly recurved that one of these snakes would be unable, even if it wished to do so, to let any prey which had once entered its mouth escape. The poisonous snakes have a special poison fang in the maxilla of each side; these have a deep groove or canal running down them which transmits the poison from the poison gland In the colubrine snakes, such as the cobra, the poison fang is always erect, but in the viperine, such as the adder and rattlesnake, there is a mechanism by which the tooth is only erected when the jaws are opened for striking. At other times the teeth lie flat in the roof of the mouth.

In the lizards or Lacertilia the teeth usually consist of a series of pegs in the upper and lower jaw, each resembling the one in front of it; sometimes, as in the chameleon, they are anchylosed by their bases to the bone, but at others, as in the iguana, they are fused by their sides to a ridge of bone which forms a low wall on their lateral surface. In the former case the dentition is spoken of as "acrodont," in the latter as "pleurodont."

In the Crocodilia the teeth are fitted into definite sockets as in mammals and are not anchylosed with the jaws. This arrangement is spoken of as "thecodont"

Existing birds are toothless, but palaeontology shows that they originally had teeth of a reptilian character.

In all these lower vertebrates, then, the teeth are similar or nearly similar in character; at least they are not divided into definite incisor, canine, premolar and molar regions. Their denti-

tion is therefore known as "homodont." Another characteristic is that in almost all of them there is an arrangement for a continuous succession of teeth, so that when one is lost another from behind takes its place, and to this arrangement the term "polyphyodont" is applied.

Mammalia.—In the Mammalia the different groups of teeth (incisor, canine, etc.) already noticed in man are found, and these animals are characterized, with some exceptions, by having a "heterodont" as opposed to a homodont dentition. In the mammals too the polyphyodont or continuous succession of teeth is reduced to a "diphyodont" dentition, which means that there is only one relay of teeth to replace the first set. In the marsupials the reduction of the succession is carried still further, for only one premolar in each segment of the jaw is replaced, while in the toothed whales there is no succession at all. When one set has to do duty throughout life the dentition is called "monophyodont."

It is uncertain how the complex back teeth of mammals with their numerous cusps were derived from the simple conical teeth which are generally assumed to have been the primitive arrangement. The "tritubercular" theory, which is most favoured, is largely based on the researches of E. D. Cope and H. F. Osborn, two American palaeontologists. According to this theory a simple peg-like ("haplodont") tooth develops two additional smaller pegs or cones, one in front and one behind the original main cone. This is known as the triconodont stage, and it is found in some of the oldest extinct mammals. As a later adaptation the two small cones become external to the original cone in the upper jaw and internal in the lower. The surface of the tooth has now a triangular shape with a cone at each angle, and this is the "tritubercular tooth" which is very common among the ancestral mammals. Other cusps may be developed later, and so the quadricuspid and quinquecuspid molar teeth of man and other mammals are accounted for.

Incisor teeth are those which in the upper jaw have their sockets in the premaxillary bone; they are generally chisel-shaped, and with their opponents of the lower jaw act like scissors. The *canine tooth* is the first tooth behind the premaxillo-maxillary suture, provided it be not far behind it; it is almost always the first of the premaxillary series, speaking accurately, which is elongated and sharply pointed. The *premolar teeth* are those in the maxillary bone which are preceded by milk teeth. The *molar teeth* are those, behind the premolars, which are not preceded by temporary teeth.

In front of the premolar teeth, and between them and the canine, if it be present, or the incisors, if it be absent, there is often a space called the "diastema." It is best marked in the Rodentia and Ungulata, and in the horse is familiar as the place where the bit lies. The elephant's tusks are modified incisors, those of the walrus and wild boar are modified canines.

Dental Formulae.—In recording the teeth of any particular mammal it saves time and space if a dental formula be used. This simply means setting down the number of each kind of tooth in one side of the upper and lower jaw in their order from before backward. Thus man's formula would be, incisors $\frac{2}{2}$, canines $\frac{1}{1}$, premolars $\frac{2}{2}$, molars $\frac{3}{3}$. This is condensed into $\frac{2.1.2.3}{2.1.2.3}$.

Some other types of dental formulae are—

Catarrhine (old world) monkeys	$\frac{2.1.2.3}{2.1.2.3}$
Platyrhine (new world) monkeys	$\frac{2.1.3.3}{2.1.3.3}$
Marmosets	$\frac{2.1.3.2}{2.1.3.2}$
Most lemurs	$\frac{2.1.2.3}{2.1.2.3}$
or	$\frac{2.1.3.3}{2.1.3.3}$
Insectivorous bats (full series)	$\frac{2.1.3.3}{3.1.3.3}$
Frugivorous bats	$\frac{2.1.2.3}{2.1.3.3}$
Insectivora (teeth variable)	
Hedgehog	$\frac{3.1.3.3}{2.1.2.3}$
Mole	$\frac{3.1.4.3}{3.1.4.3}$
Carnivora—	
Cat family (Felidae)	$\frac{3.1.3.1}{3.1.2.1}$
Dog family (Canidae), Bear family (Ursidae)	$\frac{3.1.4.2}{3.1.4.3}$
Civet family (Viverridae), Racoon family (Procyonidae)	$\frac{3.1.4.2}{3.1.4.2}$
Hyaena family (Hyaenidae)	$\frac{3.1.4.1}{3.1.3.1}$
Weasel family (Mustelidae)	$\frac{3.1.4.1}{3.1.4.2}$
Eared seal family (Otariidae)	$\frac{3.1.4.1}{2.1.4.1}$
Seal family (Phocidae)	$\frac{3.1.4.1}{3.1.4.1}$
Walrus family (Trichechidae), adult	$\frac{1.1.3.0}{0.1.3.0}$
In a young animal (probably)	$\frac{3.1.3.2}{3.1.3.1}$
Ungulata—	
Hippopotamus	$\frac{2.1.4.3}{2.1.4.3}$
Pig family (Suidae)	$\frac{3.1.4.3}{3.1.4.3}$
Camel	$\frac{1.1.3.3}{3.1.2.3}$
Chevrotain (Tragulidae)	$\frac{0.1.3.3}{3.1.3.3}$
Deer family (Cervidae)	$\frac{0.(0\text{ or }1).3.3}{3.1.3.3}$
Hollow-horned ruminants (Bovidae)	$\frac{0.0.3.3}{3.1.3.3}$
Tapir	$\frac{3.1.4.3}{3.1.3.3}$
Horse (Equidae)	$\frac{3.1.3.3}{3.1.3.3}$
Rhinoceros	$\frac{(0-2).0.4.3}{(0-1).(0-1).4.3}$
Procavia (Hyrax)	$\frac{(1-2).0.4.3}{2.0.4.3}$
Elephant	$\frac{d.i.1\ .i.1\ .c.0\ .d.m\ .(3-4)m.3}{0\quad 0\quad 0\quad (3-4)\quad 3}$

In this animal there are no premolars, but the milk molars (d.m.) and true molars gradually replace one another from before backward throughout life, so that there are never more than two back teeth in each segment of the jaw at any one time.

Rodentia—	
Typical rodents (Simplicidentata)	$\frac{1.0.(0-1).3}{1.0.(0-1).3}$
Hares and rabbits (Duplicidentata)	$\frac{2.0.3.3}{1.0.2.3}$

Cetacea.—In the living toothed whales (Odontoceti) the dentition is homodont and may be as great as $\frac{60}{60}$. There is every reason to believe, however, that they are derived from heterodont ancestors.

The homodont dentition of the whales is a retrograde process, and is therefore not comparable to the homodont dentition of the vertebrates below mammals.

Sirenia—The dentition is monophyodont. The manatee has i $\frac{2}{2}$, c. $\frac{0}{0}$, back teeth $\frac{11}{11}$.

In the Edentata the ant-eaters (Myrmecophagidae) and pangolins (Manidae) are toothless, though the latter have foetal tooth germs. The aard varks (Orycteropodidae) are somewhat heterodont, while the armadillos (Dasypodidae) and sloths (Bradypodidae) have a homodont dentition, which, like that of the whales, is retrogressive In the giant armadillo (*Priodon gigas*) the formula is $\frac{25}{25}$. This animal therefore has a hundred teeth. In none of the Edentata are the teeth covered with enamel.

In the Marsupialia the typical formula is $\frac{3\ 1\ 3\ 4}{3\ 1\ 3\ 4}$ They are divided into *diprotodont*, in which there are not more than $\frac{3}{3}$ incisors, often $\frac{3}{1}$ as in kangaroos, and *polyprotodont*, in which the incisors are more than $\frac{3}{3}$, as in the Tasmanian wolf (Thylacinus) and Tasmanian devil (Sarcophilus). The marsupial teeth are often regarded as all milk teeth

In the Monotremata the Echidna or spiny ant-eater is quite edentulous, while the duck-mole (Ornithorhynchus) has functional molar teeth in youth, though in the adult these are lost, and their place is taken by horny plates.

Reviewing the various tooth formulae of mammals the following is usually regarded as typical:

$$\frac{3\ 1\ 4\ 3}{3\ 1\ 4\ 3}.$$

This, it will be noticed, is the formula of the pig, and it is also that of almost all the Eocene Ungulata.

Brief Dental Glossary.—As the teeth are of such importance in the classification of animals, some of the chief terms by which they are described are recapitulated and briefly defined here

1. *Acrodont,* a tooth which is anchylosed by its base to the summit of a parapet on the jaw.
2. *Bilophodont,* a molar tooth having two transverse ridges on its grinding surface, as in the tapir
3. *Brachyodont,* a low-crowned molar tooth—the opposite of hypsodont.
4. *Bunodont,* a tooth bearing conical cusps.
5. *Diphyodont,* having two series of teeth (milk and permanent)
6. *Diprotodont,* a marsupial with not more than $\frac{3}{3}$ incisors, often only one on each side of the mandible.
7. *Haplodont,* a tooth having a simple conical crown with a single root.
8. *Heterodont,* a dentition in which the teeth are not all alike, chiefly characteristic of the Mammalia.
9. *Homodont,* a dentition in which the teeth are all alike, as in many of the lower vertebrates and some mammals.
10. *Hypsodont,* a high-crowned molar tooth, such as that of the horse,—the opposite to brachydont.
11. *Lophodont,* a transversely ridged molar tooth.
12. *Monophyodont,* having only one dentition (*cf.* diphy- and polyphy-odont).
13. *Multituberculate,* a tooth, the crown of which bears numerous conical cusps; held by some to be the primitive condition of the mammalian teeth.
14. *Pleurodont,* a tooth anchylosed to the inner side of a parapet on the jaw.
15. *Polybunodont,* a synonym for multituberculate.
16. *Polyphyodont,* having an endless succession of teeth, as in most vertebrates below the mammals.
17. *Polyprotodont,* a marsupial having an incisor formula of more than $\frac{3}{3}$.
18. *Protodont,* a stage met with in fossil mammals which is an advance on the haplodont tooth in that two small cusps are added to the main cone.
19. *Secodont,* a back tooth adapted to cutting, as in many of the Carnivora.
20. *Selenodont,* a molar tooth with crescentic ridges on its grinding surface, as in most ruminants
21. *Thecodont,* a tooth embedded in a socket or alveolus, as in mammals.
22. *Triconodont,* a fossil stage in advance of the protodont There are three well-marked cones in an antero-posterior line.
23. *Tritubercular,* a fossil stage succeeding the triconodont. The main cone is external in the lower teeth and internal in the upper A very common form of back tooth in fossil forms and one which gives its name to the "tritubercular theory."

TEETH, ARTIFICIAL. In the beginning of the restorative art in dentistry, artificial substitutes were human teeth, teeth of cattle and sheep, teeth carved from the tusks of the elephant, and from the tooth of the hippopotamus The first recorded substitute other than animal substances was a paste made of white wax, gum elemi and the powder of white mastic, of coral, and of pearl. It was originated by the Frenchman, Guillemeau, in 1710 In 1728 Fauchard, also a Frenchman, is credited with the development of a porcelain and a technique for making artificial teeth The porcelain teeth thus made in France were introduced into America in 1874 by Plantou Silica, kaolin and feldspar are the three basic materials used in the manufacture of porcelain teeth Silica is used as a vehicle for holding the form of the tooth; it is of selected high quality and has an exceptionally high fusing point. Kaolin adds density and strength and forms the body material of the tooth Felspar is the flux, which combines the silica and kaolin, thereby forming a porcelain that is the finest in texture, translucency and quality, with a high degree of strength, yet developed in the ceramic arts. Colour is supplied through the use of the oxides of titanium, platinum, cobalt, iron, gold and tin These materials, known as colouring frits, are incorporated with the basic ingredients to produce the tints desired.

Artificial teeth are first carved in plaster or other suitable material to a size approximately one-fifth larger than the desired finished product This allows for the shrinkage in the porcelain during the fusion process. Moulds of hard metallic substance are made from the enlarged plaster teeth and the porcelain is packed in them in the form of a paste. After hardening to a bisque form, the teeth are removed from the moulds, placed in a furnace, and fused at a temperature varying from 1,700 to 2,500° F. Crowns, facings and vulcanite teeth are the types required to meet individual needs Porcelain crowns are used to replace the crowns of natural teeth when their roots are in place. The porcelain crown is attached to the natural root by means of a post that is fitted and cemented to place. Facings are of the veneer type and are used to restore the loss of one or more teeth by bridge work Vulcanite teeth are generally used when partial or full sets of dentures are required. These teeth are attached to a base and made to fit over the various individual forms of the gums. Materials used for bases are hard rubber, gold, platinum or bakelite. The typal classification of selecting artificial teeth is the one now in current use. There are three basic typal forms of faces, square, tapering and ovoid, and the teeth harmonize with these types.

(M. M. H.)

TEGEA, an ancient Greek city of Arcadia, on a plateau enclosed by Mts. Parthenium and Maenalus on east and west, and by transverse ranges which separate it from the plateau of Orchomenus and from the Eurotas valley. Tegean territory occupied the southern part of this plain; the northern half belonged to Mantineia (*q.v.*). Its geographical position accounts for the conflicts which arose with Mantineia and with Sparta.

Tegea was one of the most ancient cities of Peloponnesus; tradition ascribed its concentration (*synoecism*) out of eight or nine primitive cantons to a mythical king Aleus. As several Cretan townships passed for colonies of Tegea, oversea connections may be inferred in prehistoric days. The prominence which legend assigns to its king Echemus in opposing the Heraclid invasion shows that it was one of the chief Peloponnesian communities in pre-Dorian days. For several centuries Tegea screened Arcadia against expanding Sparta; ultimately subdued about 550 B.C. it was allowed to retain independence and Arcadian nationality. During the Persian invasion the Tegeans displayed a readiness unusual among Peloponnesian cities; in the battle of Plataea they were the first to enter the enemy's camp. A few years later they headed an Arcadian and Argive league against Sparta, but after losing two pitched battles at Tegea and Dipaea they resumed their former loyalty about 468–467. In 423 there was open war with the Mantineians, and when the latter rebelled against Sparta and allied themselves with Argos and Athens, the Tegeans stood firmly by Sparta's side: in the decisive battle of Mantineia (418) their troops had large share in the overthrow of the coalition; and during the early 4th century Tegea continued to support Sparta against the Mantineians and other malcontents. But after the battle of Leuctra the philo-Laconian party was expelled with Mantineian help.

Tegea henceforth took an active part in the revival of the Arcadian League and in alliance with Thebes against Sparta (371–362), and the defection of Mantineia confirmed its federalist tendencies. The foundation of the new federal capital Megalopolis threw Tegea somewhat into the shade. Hostile to the Macedonians, in 266 it joined the Chremonidean League against Antigonus Gonatas. To the incorporation of Mantineia into the Achaean League (233) Tegea replied by allying itself with the Aetolians, who in turn made it over to Cleomenes III. of Sparta (228). From the latter it was transferred by Antigonus Doson to the Achaean League (222); in 218 it was again occupied by the Spartans but reconquered in 207 by the Achaean general Philopoemen. In Augustus' time Tegea was the only important town of Arcadia, but its history throughout the Roman and Byzantine periods is obscure; it ceased to exist as a Greek city after the Gothic invasion of 395. The site is now occupied by the small village of Piali.

Archaeology.—The temple of Athena Alea at Tegea is described by Pausanias as excelling all others in Peloponnese. The original temple built by Aleus, the founder of the city, was superseded by a larger one which was destroyed by fire in 395 B.C. Rebuilding was entrusted to Scopas, the great sculptor; and probably he also provided the pediment sculptures, representing at the front, the hunt of the Calydonian boar, and, at the back, the battle of Achilles and Telephus. Both subjects were intimately associated with the temple, for Atalanta had dedicated in it the face and tusks of the boar, and Telephus was the son of Heracles and the priestess Auge. Two heads of heroes and that of the boar were found before 1880; later excavation, in 1883, showed the plan of the temple, which had six columns at front and back, and thirteen at the sides. Like the temple at Phigalia (*q.v.*) it combined all three orders—Doric, Ionic and Corinthian. In 1900 the French School at Athens recovered more fragments, including a head of Heracles and the torso and possibly the head of Atalanta, these last two of Parian marble. *See* GREEK ART.

TEGERNSEE, a lake in Upper Bavaria, situated in a beautiful mountain country, 2,382 ft. above the sea, 34 m. south from Munich by rail to Gmund, a village on the north shore. The lake is 4 m. long, 1¼ broad, and about 235 ft. deep. Its waters discharge through the Mangfall into the Inn. It is one of the most frequented summer resorts in the vicinity of Munich.

The village of Tegernsee, on the east bank, has a 15th century parish church and a ducal castle (formerly a Benedictine monastery).

TEGETTHOFF, WILHELM VON, BARON (1827–1871), Austrian admiral, son of Lieutenant-Colonel Karl von Tegetthoff, was born at Maribor (Marburg) on Dec. 23, 1827. After passing through the naval college at Venice, he became ensign in 1848 and lieutenant in 1852. He served in the Crimean war, on the Mediterranean station, and in the North Sea against the Danes (1863). In 1866 he was placed in command of the effective force of the Austrian navy. The decisive victory of the Austrian fleet at Lissa over superior Italian numbers (July 20) was entirely due to the personal superiority of Tegetthoff and the officers whom he in great measure had trained. Tegetthoff was immediately promoted vice-admiral. In March 1868 he became head of the naval section of the War Office and commander-in-chief of the navy. He died at Vienna on April 7, 1871.

TEGNER, ESAIAS (1782–1846), Swedish writer, was born on Nov. 13, 1782, at Kyrkerud in Wermland. His father, a pastor, whose name had been Esaias Lucasson, took the surname of Tegnerus—altered by his fifth son, the poet, to Tegnér—from the hamlet of Tegnaby in Småland. In 1792 Tegnerus died. In 1799 Esaias Tegnér, educated in the country, entered the University of Lund, where he graduated in philosophy in 1802, and continued as tutor until 1810, when he was elected Greek lecturer. In 1806 he married Anna Maria Gustava Myhrman. In 1812 he was named professor, and continued as a lecturer in Lund until 1824, when he was made bishop of Vexiö. At Vexiö he remained until his death, twenty-two years later. Tegnér's early poems have little merit. He was comparatively slow in development. His first great success was a dithyrambic war-song for the army of 1808, which stirred every Swedish heart. In 1811 his patriotic poem *Svea* won the great prize of the Swedish Academy, and made him famous.

In the same year was founded in Stockholm the Gothic League (*Götiska förbundet*), of young and patriotic men of letters, of whom Tegnér quickly became the chief. The club published an excellent magazine, *Iduna*, in which it urged the study of old Icelandic literature and history. Tegnér, Geijer, Afzelius, and Nicander became the most famous members of the Gothic League. Tegnér's fame rests principally on three longer poems *Nattvardsbarnen* ("The First Communion," 1820), well known in Longfellow's version; *Frithjofs saga* (1820–25), a romantic paraphrase of an old saga, which was translated into nearly every European language; and the romance, *Axel* (1822). In later years Tegnér began, but left unfinished, two important epic poems, *Gerda* and *Kronbruden*.

The period of the publication of *Frithjofs saga* (1825) was the critical epoch of his career. It made him one of the most famous poets in Europe; it transferred him from his study in Lund to the bishop's palace in Vexiö; it marked the first breakdown of his health, which had hitherto been excellent; and it witnessed his unhappy passion for Euphrosyne Palm. On Nov. 2, 1846, he died in Vexiö. From 1819 he had been a member of the Swedish Academy, where he was succeeded by his biographer and best imitator Böttiger.

See Böttiger, *Teckning af Tegnérs Lefnad;* Georg Brandes, *Esaias Tegnér;* Thommander, *Tankar och Löjen;* E. Böök, *Esaias Tegnér* (vol. i., 1917).

TEGUCIGALPA (tä-gōō-thē-gahl'pą), the capital of Honduras and of the department of Tegucigalpa; 3,200 ft. above sea-

level, on the Choluteca, at the head of a highway to the port of San Lorenzo on Fonseca bay. Tegucigalpa is the only capital in the Americas excepting Asunción, Paraguay, which is without a railway. Pop. (1925) 38,950 Tegucigalpa became capital of Honduras, a status it had previously shared with Comayagua, in 1880. During the 18th century the neighbourhood was famous for its gold, silver and marble, but in modern times the mines and quarries have greatly declined in value, and farming is the chief local industry.

TEHRAN (tē-rahn′), capital of Persia and of a province of that name, is situated in 35° 41′ N., 51° 25′ E, at an elevation of 3,810 ft, on an extensive gravel deposit which slopes down from the foot of the Elburz mountains (some 10 m. distant) and extends for 5½ miles beyond the city, on the south. It occupies a radical position in Persia commanding routes in all directions, Isfahan being 224 m distant on the south, Bushire 677 m., Baghdad 500 m west, Tabriz 374 m. north-west, Meshed 471 m. north-east, Herat 672 m., and the Caspian sea 70 m. distant.

Streets and Buildings.—Formerly Tehran consisted of a fortified polygon of 4–5 m. circuit surrounded by a battlemented mud wall 20 ft. high flanked with circular towers and having a dry ditch and six gates. In 1869 Nasr-ud-Din Shah decided upon enlarging the city, the old walls and towers were demolished and replaced by a moat and earthen ramparts 12 m. in circumference, constructed on the plan of the fortifications of Pavis as they were before the Franco-German War, and completed in 1874. The city now encloses an area 7½ miles square, with 12 gates consisting of lofty archways adorned by turrets. The principal public place is the Maidan Tupkhaneh or Artillery Square, 270 yd by 120, surrounded by barracks; another square is the great Maidan-i-Mashq, the military parade ground, 550 yd. by 350. From the Tupkhaneh two broad streets planted with poplars run in a northerly direction towards the outer walls, the westerly called the Khaiban-i-Dawlat, where are many foreign residences.

Occupying a space nearly a quarter of a mile square south of the Maidan Tupkhaneh, the site formerly of the ark or citadel, is a collection of gardens, courts and buildings attached to the royal palace, within the precincts of which are the *Talar*, or throne room, in which is the white marble throne or *Takht-i-marmar* of Kerim Khan Zand brought from Shiraz; and in the council chamber is the *Takht-i-taus*, or Peacock throne, not however that of the Mogul emperors brought by Nadir Shah from India, but a throne made for Fath Ali Shah

A census taken in 1919 gave a population of 250,000, which is supposed to be a decrease of 100,000 from the population of 1917–18, due to visitations of famine, influenza and typhus in that year. The great proportion are Farsi-speaking Persians and Shiah Mohammedans Baha'is are numerous and there are a number of Armenians (some 5,000) mostly shop-keepers, also some Jews and Chaldeans. Tehran has a municipality under the guidance in 1928 of an energetic army officer and municipal conditions show some progress.

In Tehran there are medical, art, industrial, political science, law, military, agricultural and normal schools, some of which are under foreign direction and all staffed, in part, by foreign instructors. The American Presbyterian Mission has also an institution enrolling 670 students, 500 of college grade.

The water supply is almost wholly from *kanats* bringing water from the Shimran slopes of the Elburz. There are some 40 of them, 5–8 m. in length, the majority fed from underground sources, and entirely dependent upon the snow and rainfall.

The climate of Tehran used to be considered somewhat unhealthy, particularly in summer and early autumn, when typhoid, ague and other fevers were frequently prevalent; but something in the way of sanitation has been effected of late years and there has been a distinct improvement in the health of the city. For the years 1902–12, the average maximum shade temperature was 104·6° F, the average minimum 14·7°; the highest shade temperature registered was 109° and the lowest 6°. The average rainfall over a period of 15 years was 9·3 in.

A state-owned electric light plant provides lighting from sunset to 11 P M There is otherwise no general lighting of the streets at night, except that the municipality provides a few wick lamps in some of the main thoroughfares. A single track of tramway of about 6 m. traverses the city from east to west from the Abdul Azim gate to the Kazvin gate, and from the bazaars to the north. A single line of railway was laid in 1888 to Shah Abdul Azim about 5 m. south of the city. The telephone service within Tehran, and outside it to the principal summer resorts, is effectively maintained by the *Société Anonyme des Téléphones Persans;* in 1925–6 the subscribers numbered 1,372. Metalled roads passable for all kinds of motor transport at practically all seasons lead via Kazvin to Kermaushah and Resht, to Qum and Sultanabad (195 m.), and to Isfahan; and partly metalled roads to Meshed (566 m.), to Demavend (39 m.) and to Saveh and Hamadan (213 m.).

BY COURTESY OF THE PRESBYTERIAN BOARD OF FOREIGN MISSIONS

THE DAUGHTER OF A RUG-MAKER OF TEHRAN

TEHRAN PROVINCE is bounded north by Mazanderan, west by Kazvin and Hamadan, south by Qum, and east by Semnan-Damghan provinces, and it embraces a large part of the southern slopes of the Elburz range, while again to the south is found the Daria-i-Namak, a salt lake, or morass, which extends for 150 m. E and W and has a breadth of 35 m. in some places

History.—Though a modern capital Tehran is old historically, but was for long small and insignificant. It is thought that the name means "the plains" in contradiction to *shamran, i e*, "mountains." Almost the earliest mention of the place is by Yaqut (12th century) who speaks of its houses, constructed underground It is described by Hamdullah Mustawfi, in the 14th century, as a town of some size and importance.

Under the later Safavis (end of the 17th and beginning of the 18th centuries) Tehran was sometimes the residence of the court. Sir Thomas Herbert who visited the city in 1627 states that it then contained 3,000 houses built of sun-dried bricks and supplied with water from a little river. The town was taken and pillaged by the Afghans in 1723; and receives mention by Jonas Hanway, 1744. With the rise of the Qajar dynasty at the close of the 18th century, the first epoch of the city's ascendancy began, Agha Mohammed Khan selecting it, about 1788, to supersede Isfahan or Shiraz as his capital, because of its proximity to Mazanderan, the starting point from which he had conquered the country and to which he could retire if hard pressed Agha Khan, however, did little for the city after making it the capital.

Under the rule of Fath Ali Shah the city so increased in size and population that when visited by Ouseley and Morier about 1810, it had 12,000 houses and 40,000–60,000 people It remained at about this size for the first seventy years of the 19th century until it underwent an entire renovation at the hands of Nasr-ud-Din Shah

TEHRI, a mountain state in Northern India, politically connected with the United Provinces· area 4,180 sq m.; population (1921) 318,414 It lies entirely amid the Himalayas, containing ranges from 20,000 to 23,000 ft. above sea-level, and also the sources of both the Ganges and the Jumna, with the places of pilgrimage associated with them. The forests, which have been leased to the British government, are very valuable, yielding several kinds of pine, oak and cedar. The chief, whose title is raja, is descended from a Rajput family which formerly ruled over all Garhwal, and enjoys a salute of 11 guns. The existing state was created by the British after the war with Nepal in 1815

TEHUANTEPEC (tä-wahn-tä-pĕk), the town which gives its name (from *tecuani-tepec*—"jaguar-hill") to the isthmus, gulf and railway, stands on the Tehuantepec river about 15 m. from its mouth and 13 m. by rail from Salina Cruz. Pop. (1921) 9,252. It is a typical, straggling Indian town, occupying the slope of a hill on the Pacific side of the divide, with a beautiful view of the river valley and the distant sierras to the north. The streets are little more than crooked paths up the hillside, and the habitations are for the most part thatched, mud-walled huts. The population of the town and of the surrounding district is composed almost wholly of Indians of the great Zapoteca family.

INDIAN WOMEN OF TEHUANTEPEC IN NATIVE COSTUME

TEHUANTEPEC, an isthmus of Mexico lying between the gulfs of Campeche (Campeachy) and Tehuantepec, with the Mexican States of Tabasco and Chiapas on the east and Vera Cruz and Oaxaca on the west. It includes that part of Mexico lying between the 94th and 96th meridians of longitude W., or the south-eastern parts' of Vera Cruz and Oaxaca, with perhaps small districts of Chiapas and Tabasco. It is 125m. across at its narrowest part from gulf to gulf, or 120m. to the head of Laguna Superior on the Pacific coast. The Sierra Madre breaks down at this point into a broad, plateau-like ridge, whose elevation, at the highest point reached by the Tehuantepec railway (Chivela pass) is 735 feet. The northern side of the isthmus is swampy and densely covered with jungle. The whole region is hot and malarial, except the open elevations where the winds from the Pacific render it comparatively cool and healthful. The annual rainfall on the Atlantic or northern slope is 48 in. (10 year average) and the maximum temperature about 95° in the shade. The Pacific slope has a light rainfall and dryer climate.

Since the days of Cortés, the Tehuantepec isthmus has been considered a favourable route, first for an interoceanic canal, and then for an interoceanic railway. Its proximity to the axis of international trade gives it some advantage over the Panama route, which is counterbalanced by the narrower width of Panama. When the great cost of a canal across the isthmus compelled engineers and capitalists to give it up as impracticable numerous projects for the construction of a railway were undertaken and abandoned. At last, in 1899 work was undertaken for the Mexican Government and was finished to a point where its formal opening for traffic was possible in 1907.

The railway is 192m. long, with a branch of 18m. between Juile and San Juan Evangelista. The minimum depth at low water in both ports is 33ft., and an extensive system of quays and railway tracks at both terminals affords ample facilities for the expeditious handling of heavy cargoes. At Santa Lucrecia, 109m. from Salina Cruz, connection is made with the Vera Cruz and Pacific railway (a government line), 213m. to Cordova and 311 m. to Mexico city.

TEHUELCHE, an almost extinct Indian tribe once occupying the plains of Patagonia from the Río Negro to the Straits of Magellan. Their great stature and physical vigour have created a giant-tradition in European literature. As the arid, wind-swept nature of Patagonia unfits it for agriculture, the Tehuelche necessarily were nomadic hunters. Before the 16th century they lived much as did their kinsmen, the Ona, in Tierra del Fuego, but the advent of the horse resulted in greatly enlarging their sphere of action and in various cultural changes.

See G. C. Musters, ***At home with the Patagonians*** **(London, 1871);** F. F. Outes, ***La edad de piedra en Patagonia*** **(Buenos Aires, 1905).**

TEIGNMOUTH, JOHN SHORE, 1ST BARON (1751–1834), governor-general of India, was born on Oct. 8, 1751, the son of Thomas Shore, a supercargo in the service of the East India company. He was educated at Harrow, and went out to India as a writer in the Bengal Civil Service in 1769. He became a member of the Supreme Council (1787–89) and assisted Lord Cornwallis in introducing many reforms, but did not approve his permanent settlement of Bengal. On the retirement of Cornwallis, he was appointed governor-general (1793–98), adopting a policy of non-interference, but he deposed Wazir Ali, for whom he substituted Saadat Ali as nawab of Oudh. He met a mutiny of the officers of the Indian army with concessions. He died on Feb. 14, 1834.

See *Memoirs of Lord Teignmouth*, by his son (1843).

TEIGNMOUTH, a seaport, seaside resort and market town in the Totnes parliamentary division of Devon, England, at the mouth of the river Teign, on the English Channel, 15 m. south-by-east of Exeter, by a branch of the G.W. railway. Pop. of urban district (1921) 10,970. Two parishes, East and West Teignmouth, form the town. It lies partly on a peninsula between the river and the sea, partly on the wooded uplands which enclose the valley and rise gradually to the high moors beneath Heytor.

Teignmouth (*Teinemue, Tengemue*) possessed a church of St. Michael as early as 1044, when what is now East Teignmouth was granted by Edward the Confessor to Leofric, bishop of Exeter. In the middle ages Teignmouth was already a flourishing port, able to furnish 7 ships and 120 mariners to the Calais expedition of 1347, and depending chiefly on the fishing and salt industries. Teignmouth was burned by French pirates in 1340, and was again devastated by the French on the 26th of June 1690.

TEIRESIAS, in Greek legend, a famous Theban seer, son of Eueres and Chariclo, a descendant of the *Spartoi* (*see* CADMUS). He was blinded early in life either because he saw Athena (or Artemis) bathing naked, or because he told Zeus and Hera that women had far more pleasure of love than men, thus bitterly offending the latter. At all events, he was comforted by the gift of seer-craft and granted a very long life, finally being allowed, even in Hades, to retain his wits and not be a mere phantom. As a result of killing coupling snakes he turned into a woman; years later he repeated the action, and became a man again. He died just after the capture of Thebes by the Epigoni (*q.v.*). His grave was at the Tilphusian spring; but there was a cenotaph of him at Thebes, and also in later times his "observatory," or place for watching for omens from birds, was pointed out (Pausanias ix. 16; Sophocles, *Antigone*, 999). He had an oracle at Orchomenus, but during a plague it became silent and remained so in Plutarch's time (*De Defectu Oraculorum*, 44).

TEISSERENC DE BORT, LEON PHILIPPE (1855–1913), French meteorologist, was born in Paris on Nov. 5, 1855, the son of an engineer. He began his scientific career in 1880, when he entered the meteorological department of the Bureau Central Météorologique in Paris under E. E. W. Mascart. In 1883, 1885 and 1887 he made journeys to north Africa to study geology and terrestrial magnetism, and during this period published some important charts of the distribution of pressure at a height of 4,000 metres. In 1892 he became chief meteorologist to the Bureau, but resigned in 1896, and founded a private meteorological observatory at Trappes, near Versailles, where he carried out investigations on clouds and the problems of the upper air. In 1898 he published an important paper in *Comptes Rendus* detailing his researches by means of balloons into the constitution of the atmosphere. His discovery of the so-called isothermal layer, or stratosphere, as it is now generally called, will always stand out as one of the most important events in the study of the upper atmosphere. He also carried out investigations in Sweden and over the Zuider Zee, the Mediterranean and the tropical region of the Atlantic, and fitted out a special vessel in order to study the currents above the trade winds. He collaborated with Hugo Hildebrandsson in *Les Bases de la météorologie dynamique* (1900–05). He died at Cannes on Jan. 2, 1913.

TEKTITE, the name given by F. E. Suess to the glass bodies occurring isolated on the surface or in gravels, in Moravia

and Bohemia, where they are called moldavites, the East Indies, where they are known as billitonites, and Australia, there known under the name of australites and obsidianites (from Gr. τηκτός, melted). In Tasmania, an exceptional type is met with in the Mt. Darwin region on the west coast; these glass bodies are known as Darwin glass (or queenstownite). Isolated types of tektites have also been seen in Sweden and Colombia (South America).

In the Moldau district of Bohemia the moldavites occur as flat, rounded or ellipsoidal bodies of a bottle-green colour, and usually with a pitted or corrugated surface The homes of these tektites are river gravels or deposits of late Tertiary or Recent age. The colour of this material led to its being commonly called *Bouteillenstein*. Australites are found distributed over wide areas remote from volcanic regions in Australia, principally in Victoria and the central goldfields of Western Australia. They exhibit a great variety of curious forms suggestive of flight and rotation while in a molten or plastic state These shapes are ellipsoidal, pear-shaped or button-like with a projecting rim like a saucer. They are darker and less transparent than moldavites. Billitonites resemble australites more than moldavites, being dark like the former. They occur in river gravels in the island of Billiton, and are for the most part roughly spherical or ellipsoidal and possess glossy, deeply sculptured surfaces. Billitonites reach in size up to 3 in. in diameter and in weight to 16 ounces.

Composition.—While possessing the silica content of natural obsidians (70–90% SiO_2) the tektites contain a higher percentage of iron and magnesium, and excess of calcium and potassium over sodium. Nor do they contain, with one doubtful exception, signs of incipient crystallization as is common in obsidians. The distinctive chemical composition of these bodies is reflected in their specific gravity and light refraction, which enables them to be separated from rhyolite and trachyte obsidians They have been claimed as originating by the fusion of dust in the air by lightning and that they are really fulgurites, but little can be said for this view. Though they are of widely different composition from the iron or ultrabasic meteorites, a meteoritic origin remains as the least objectionable of all theories

Analyses of some typical tektites are given below

	SiO_2	Al_2O_3	Fe_2O_3	FeO	MgO	CaO	Na_2O	K_2O
1.	77 75	12 90		2 60	0 22	3 05	0 26	2 58

TELAMON (mod. TALAMONE), an ancient city on the coast of Etruria, 11 m. N. of Orbetello. It was an Etruscan harbour, and the decorative terra-cottas of a temple which was restored in the 3rd century B C. have been found. Marius disembarked here on his return from Africa in 87 B.C.; and the harbour, which is well protected, was of some importance in the Middle Ages. It is now used only by the Italian navy.

TELANG, KASHINATH TRIMBAK (1850–1893), Indian Orientalist, was born at Bombay on Aug 30, 1850. In 1889 he became a judge of the high court, where his judgments are recognized as authoritative. He was a great Sanskrit scholar, his translation of the *Bhagavadgita* into English is a standard work, and he criticized Professor Weber's theory of Homeric influence on the *Ramayana*. He died at Bombay on Sept. 1, 1893

See R. West's *Telang's Legislative Council Speeches* (Bombay, 1895).

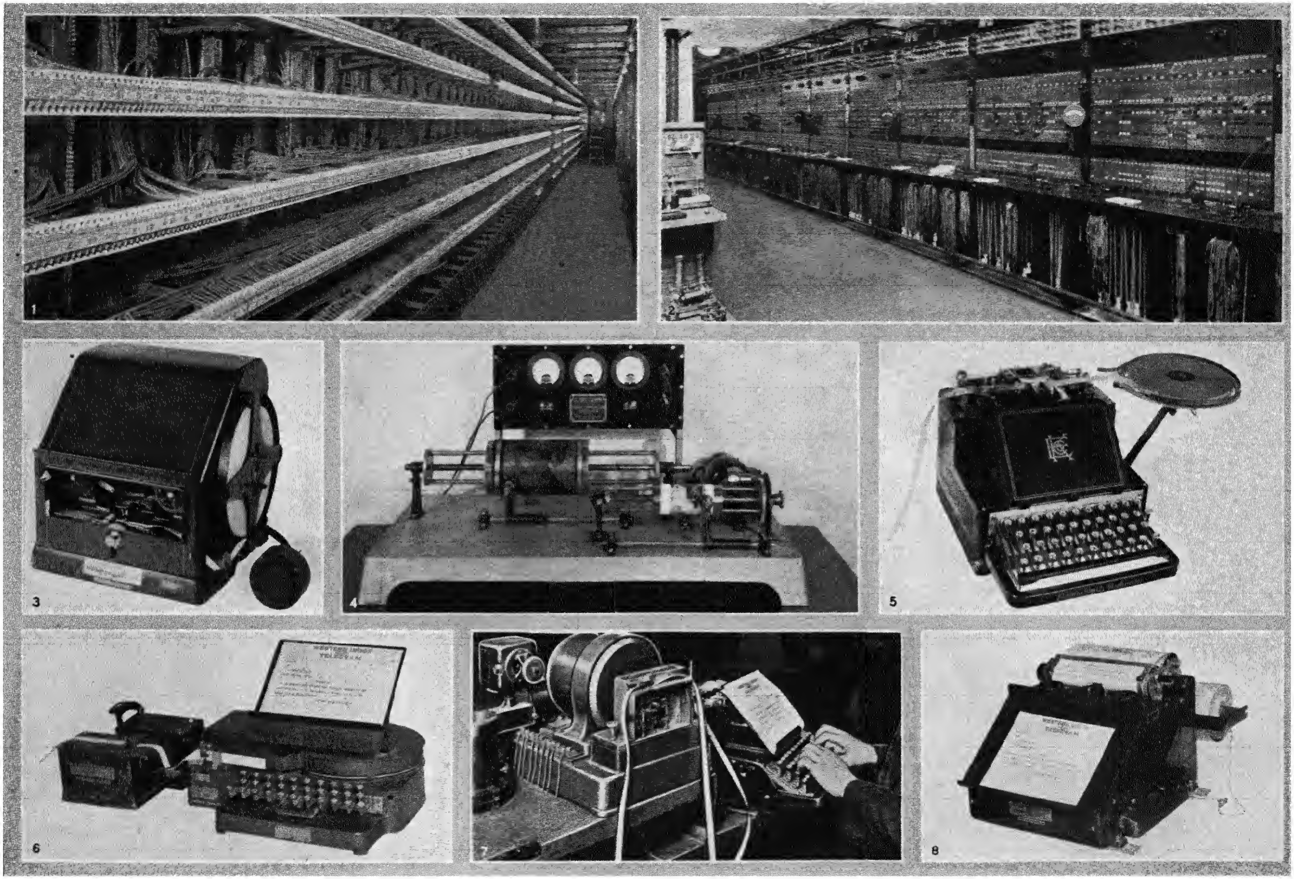
TELAV, a small town in the Georgian S.S.R., on the Alazan river, alt. 2,420 ft, in 41° 55′ N, 45° 24′ E., on a branch railway from Tiflis. Its population (8,766 in 1926) is mainly occupied in silk weaving and wine production Founded in 893, it was the capital of Kakhetia until 1797 and the ruins of its forts still exist. In its environs are religious foundations of great antiquity, the 6th century Ikaltoi monastery, the Alaverdi church founded in the 10th century and the 16th century Shuanty monastery.

TELECHRON, an electric timekeeper invented by Henry E. Warren which is operated and regulated by alternating current. The motive power is a small self-starting motor running in exact synchronisation with a central station generator. A telechron will not operate on direct current nor will it keep correct time on an unregulated alternating current service, but many power companies are holding their frequency so close that the instantaneous error is never great. Telechrons are connected to electric outlets in exactly the same manner as any other electric device

TELEGRAPH. (*See* also SIGNALLING.) Before the Christian era the bounds of electrical knowledge were confined to two facts: the attracting properties of rubbed amber, and the magnetic attraction of the lodestone; but although these phenomena were noted by Homer in the 12th century B C and others in later years, no attempt was made to explain them until the 13th century A D In 1267 Roger Bacon published his theories on the polar attraction of the lodestone. Following upon this publication rumours appear to have been circulated in connection with "a certain sympathetic needle" with which it was possible to converse over long distances. The *sympathetic telegraph* was first described in print by Porta in 1558. It consisted of two needle-shaped pieces of steel, each mounted at the centre of a dial with letters equally spaced around the periphery. Having "magnetized both needles by the same lodestone" by rubbing, a movement of the needle of one instrument was supposed to cause a synchronous movement of the needle on the other instrument, and communication, it was thought, could thus be set up between two distant points. Two experimenters who may be said to have laid the foundation for scientific electrical research were Gilbert and Cabeo; in 1600 the former found that a large number of substances which he called "electrics" *attracted* light bodies when rubbed, and that a bar of steel heated and cooled while in the magnetic meridian acquired magnetic polarity, *i.e*, pointed north and south; the latter went a step further when he described in 1629 his theory of electrical *repulsion* in similarly electrified bodies. In 1650, von Guericke devised the first electrical machine, consisting of a sulphur ball which was revolved and rubbed with the hand. Newton in 1675 substituted a glass globe for the sulphur ball, and in 1720 Gray and Wheeler discovered and tabulated the electrical conductivity of different bodies. No practical results were obtained, however, until the principle of the Leyden jar—the forerunner of the modern electrical condenser—was demonstrated by Musschenbroeck in 1745 He found that the effect of a charged Leyden jar may be conveyed to a distance by means of a wire conductor. That same year Franklin in America communicated to Collinson in England the results of his investigations in connection with electricity and its place in nature A year later Watson in England demonstrated that an electric current can be transmitted through 10,600 ft. of wire, using the earth for the completion of the circuit

Pithball Telegraphs.—Seven years after Watson's discovery the first practical suggestion for an electric telegraph was made in Scotland by an anonymous writer to the *Scots Magazine* signing himself C.M, who advised using an insulated wire for each letter of the alphabet. At the receiving end of each wire a light ball was to be suspended above a piece of paper marked with an alphabetical letter. As a charge was sent along a given wire the ball would attract the paper beneath it, and by observing the movements of the paper words could be spelt out. He further suggested that bells might be substituted for the papers, which could be struck in turn by the ball as a charge was sent along any desired wire. The idea was carried out by Le Sage in Geneva in 1774 and similar telegraph systems were also suggested by Betancourt and Lomond in 1787. An important advance was made in the latter's instrument as only one wire conductor was employed, and an alphabet of motions; but he employed a return wire instead of the ground to complete the circuit.

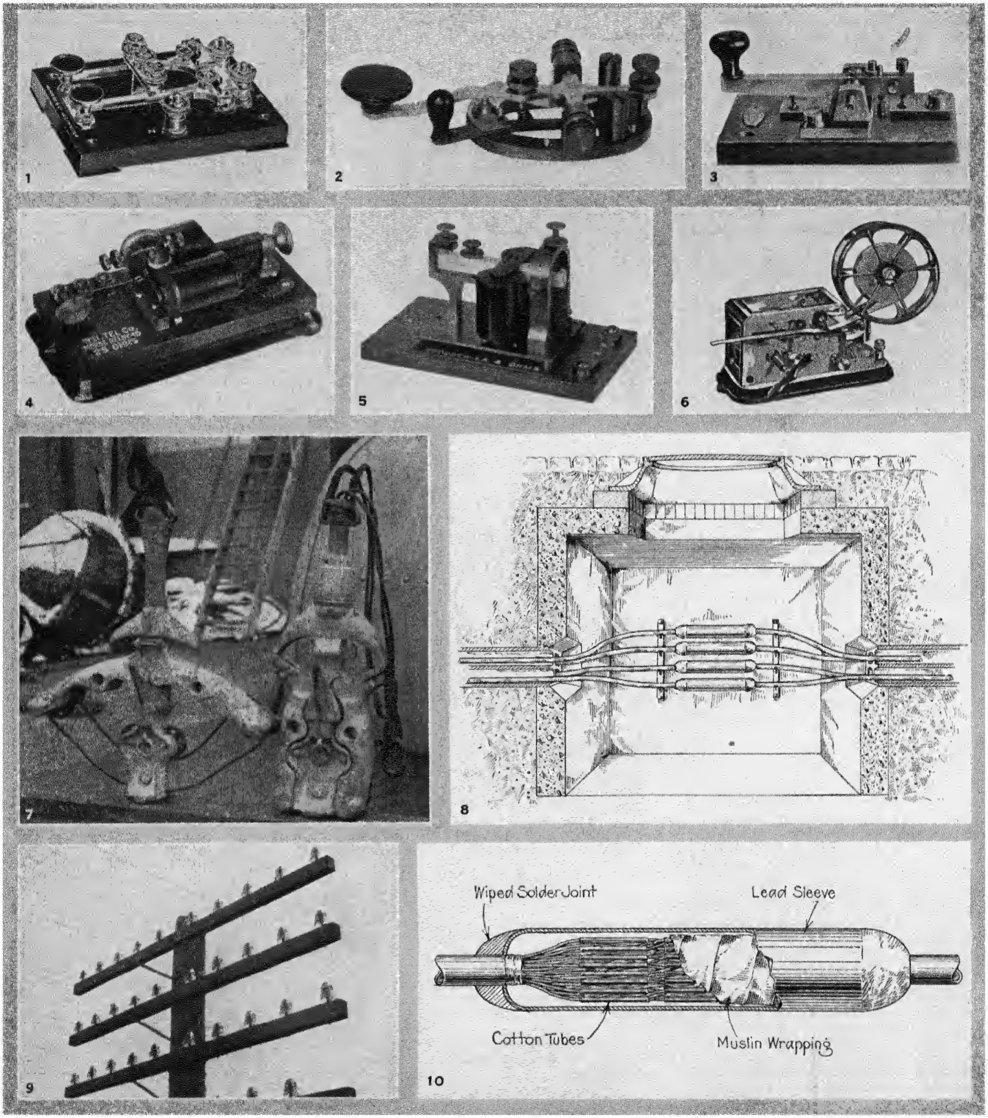
Spark Telegraphs.—Then followed the spark telegraphs of Reizen (1794), Salva (1798) and Ronalds (1816), who each proposed a system of visual telegraphy by interrupting electric circuits, causing an electric spark to appear at the point of dis-



TELEGRAPHIC EQUIPMENT

1. Distributing frame, where the incoming wires (usually in cables) are cross-connected to the office equipment
2. Telegraph switchboard
3. A late model electric tape printer
4. Combined transmitter and receiver for Telephotographic system
5. Cable code perforator
6. Transmitter and perforator; five unit code
7. Cable perforator and transmitter
8. Page printer

TELEGRAPH



EQUIPMENT USED IN TELEGRAPHY

1. Double-lever sending key
2. Modern American Morse sending key, single lever showing horizontal knife switch for making and breaking the circuit
3. European open-circuited key single lever
4. Modern American Morse relay, an auxiliary electromagnet which receives currents from the line and is thereby actuated to open and close the circuit of local battery and furnish to the receiver a requisite strength of current
5. Modern American Morse sounder or receiving instrument employed in connection with the relay for enabling operators to read by sound only
6. Morse register or recorder. The telegraphic-code message is written, printed or embossed upon the paper tape
7. An improved Lucas cutting grapnel, showing open and closed position used in submarine cable work where the depth is 1,000 fathoms or more
8. Cross-section of a manhole showing the cable ducts and joint rack
9. Cross-arms showing units and insulators used on open-wire pole lines
10. Standard cable splice. The wires are soldered intertwisted and insulated from each other by cotton tubes. A lead sleeve is soldered over the splice to the lead cover of the cable for protection

connection of each wire as desired. In Reizen's instrument each letter was represented by spaces cut out of parallel strips of tin foil pasted upon a glass table. Upon the passage of an electric current a spark appeared at each point of disconnection directly behind the cuts in the tin foil, thus rendering the whole letter visible. Seventy-two wires connected the receiving and sending stations, which consisted of two identical tables placed at separated points. The apparatus was not tested to any extent. In Salva's instrument six to eight wires by different combinations could be arranged to indicate the 26 letters of the alphabet. Ronalds's telegraph was worked in England in 1823. The transmitting and receiving apparatus consisted of circular brass plates on which were inscribed letters, figures and code letters; in front of each plate was a disc with an aperture which allowed one letter and its corresponding figure to be visible. The plates rotated by clockwork at the rate of one revolution per minute, the same letter being displayed simultaneously at both ends. A crude electrical machine charged the line as desired and the divergence of a pair of pith balls in front of the disc indicated to the receiving operator that the letter or sign visible at that moment was to be recorded. In these experiments frictional electricity was employed which was fitful and difficult to insulate on account of its high tension.

Towards the end of the 18th century, however, Galvani and Volta conducted electrical experiments which revolutionized preconceived ideas of electricity and its effects. In 1786 Galvani accidentally discovered that it was possible to cause a direct or continuous flow of current along an electrical conductor by bringing two dissimilar metals into contact with a moist substance, such as animal tissues. This led Volta in 1800 to introduce an electric battery, which became known as the *voltaic pile*, the principles of which are still embodied in the modern battery; and that year Salva demonstrated that voltaic currents could be used for transmitting signals.

Electrolytic Telegraphs.—An immediate result of the introduction of the voltaic pile was the discovery by Nicholson and Carlisle in 1801 that the passage of an electric current caused decomposition of liquids into their constituent elements. Based on this principle, Salva, in 1805, and Soemmering, in 1809, each introduced an apparatus in which a voltaic pile was used for sending signals whose presence were indicated at the receiving end by the liberation of bubbles of hydrogen. In the latter's instrument 35 wires, each allotted to the German alphabet and the ten numerals, terminated in a receptacle containing water (fig. 1). At the sending station a key which brought a voltaic battery into circuits was connected, as required, to each of the line wires, and the message was read by observing at which end of the terminals the bubbles of gas appeared. The later researches of Davy on the decomposition of chemical compounds by the electric current were applied in America to another type of telegraph by Coxe in 1816, and Dyer in 1828, who each operated a signal

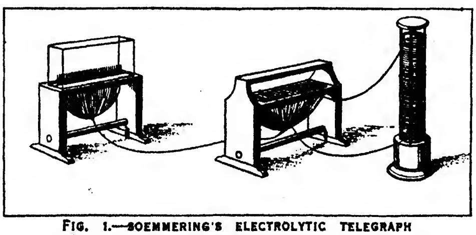


FIG. 1.—SOEMMERING'S ELECTROLYTIC TELEGRAPH

telegraph using the electric current to produce electrical decomposition at the end of the wire conductors. In the former's apparatus a voltaic current was employed. He used 36 wire conductors and 36 "return wires." Dyer, who operated his telegraph line over 8 m. on a racecourse in Long Island, used a single wire and ground circuit, and obtained red marks on litmus paper by discolouration, but he used frictional electricity, and the system was abandoned in 1830.

Electro-magnetic Needle Telegraphs.—At the beginning of the 19th century a new set of ideas followed the introduction of the electro-magnet. In 1819 Oersted discovered that a magnetic needle could be deflected from its normal position by passing a current through an adjacent wire; and that the deflection was to the right or left, according to the direction of the current. Schweigger a year later found that the deflection of the needle could be increased by surrounding it with a number of separated turns of naked wire. Following upon these experiments Sturgeon in England, in 1825, produced and named the electro-magnet (fig. 2). This consisted of a piece of soft iron in horseshoe form which was surrounded by a number of turns of wire. Upon the passage of a current through this wire the soft iron horseshoe attracted a smaller bar or armature of soft iron towards it. Four years later Henry, in America, improved Sturgeon's magnet by surrounding it with nine coils, each composed of 60 ft. of insulated wire, thus greatly increasing the power with which the armature was attracted. In 1831 Henry constructed and successfully operated an electro-magnetic signalling apparatus which consisted of a magnetized steel bar 10 in. in length, which was supported on a pivot in an horizontal position with its north end between the two arms of a horseshoe magnet. When the latter was energized by the current, the end of the bar was attracted by one arm of the horseshoe and repelled by the other, causing its further extremity to strike a suitably adjusted bell, and a code was arranged by varying sound combinations.

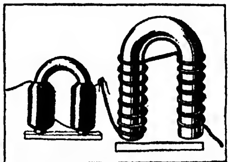

FIG. 2.—ELECTRO-MAGNETS

The action of the electric current on a magnet was first applied to electric telegraphy by Ampère, in 1820, at the suggestion of Laplace that the deflections of small magnets placed at the receiving ends of 26 wires could be used to indicate the letters of the alphabet. Ampère's apparatus was the pioneer of a number of needle instruments which came into extensive use between the years 1829 and 1841. The names of Gauss and Weber, Cooke and Wheatstone, and the brothers Highton, are associated with some of the more important needle instruments. Gauss and Weber also conducted important experiments on line conductors, in which they demonstrated that the conductor need not be insulated over its entire length. In their experiments they used a single-needle telegraph to communicate with each other and proved that by proper combination five signs are sufficient for communication. In the early experiments of Cooke and Wheatstone five needles were employed; the number was afterwards gradually reduced to two, which indicated letters by their separate and combined movements. In the single-needle instruments a magnetic needle was pivoted in the centre of a wire coil and a pointer, attached to the needle, swung in front of a dial. Deflections to right or left signified given letters. These deflections were produced by sending over the wire pulsations of one polarity, or alternations of both, as required by the letter to be transmitted.

Morse Electro-magnetic Recording Telegraph.—Morse of America conceived the idea of the first practical recording telegraph while returning from Europe on the packet-ship "Sully" in Oct. 1832. In the course of conversation on board ship Faraday's recent (1831) publication on magneto-electric induction—the current being induced by passing a magnet through a helix of wire forming part of a closed circuit—was discussed, and the fact that a charge of electricity can thus be almost instantaneously passed along a length of wire was referred to by Dr. Watson of Boston. These two facts led Morse to the conclusion that if the presence of electricity could also be detected in any desired part of the circuit it should be possible to record signals instantaneously by opening and closing the circuit. Before his arrival in New York on Oct. 13, Morse had made his plans for a telegraph recording instrument, and laid the principles for his dot-dash-space code based on the duration or the absence of the electrical impulse over a circuit. Three years later Morse constructed an experimental model of his telegraph (fig. 3) which, by the mechanical action of an electro-magnet *A*, operated a lever *B* carrying a pencil *C* at

one extremity. The passage of electrical impulses through the electro-magnetic circuit caused the pencil to move in contact with a paper tape *D* passing over a revolving cylinder *E* directly under the pencil, thus drawing an undulated line embodying his code. The speed of the paper was regulated by clockwork *F* A single wire conductor connected one pole of the battery *G* to one end of the helix of the electro-magnet; the other end of the helix was connected to one of two cups of mercury on the "port rule," the

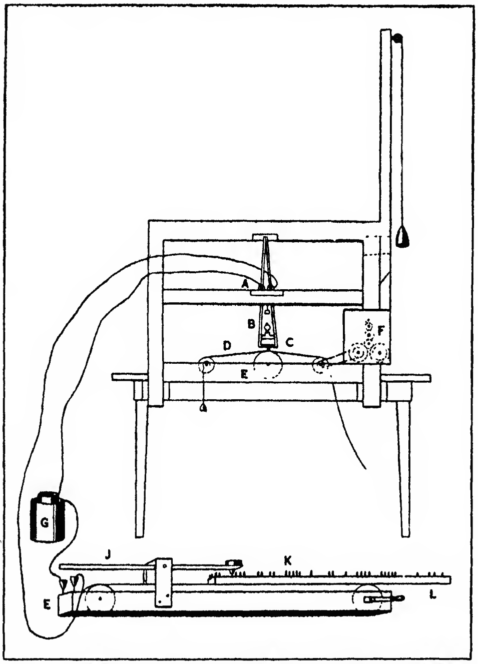

FIG 3 —EXPERIMENTAL MODEL OF MORSE ELECTRO-MAGNET TELEGRAPH

second cup being connected to the second pole of the battery, so that the only part of the circuit not complete was between the two cups of mercury *H* The electric impulses were imparted to the wire at the sending end by causing the metallic projections at the end of the lever *J* to dip into the two mercury cups, thus closing the circuit The projections *K* arranged on the 3 ft. piece of wood *L* actuated the lever and were so spaced as to form his code. This crude model was privately exhibited at New York University in 1835, and enlisted the interest of Gale and Vail

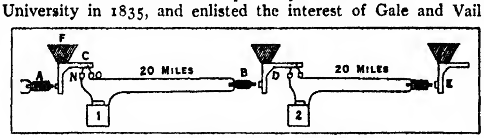

FIG 4 —DIAGRAM OF THE MORSE RELAY

The latter subsequently furnished Morse with the means, material and labour for an experiment on a larger scale

Morse Relay—In 1836 Morse constructed duplicate apparatus so that the telegraph might be operated in either direction. As the experiments progressed it was found that the electric current, after passing over a wire 20 m or so in length, became too feeble to operate the receiving apparatus directly. With the assistance of Gale and Henry, Morse devised a relay which would automatically repeat signals into another section of line and join circuits in this manner for any desired distance. The application of these relays is shown in fig. 4. Suppose the sent current is received in relay magnet *A*, energization of this magnet will cause its armature to be rotated against the retractile force of counterweight *F*, causing the wire *C* to dip into mercury cups *N* and *O*, thus closing the circuit through battery I, relay magnet *B*, and the second section of line. The second relay actuated by magnet *B* will respond in a similar manner and repeat into a third section, etc., until the receiving apparatus is finally actuated.

Morse Key—In the improved apparatus, for which Morse filed a caveat in the U.S. Patent Office on Oct. 6, 1837, a number of modifications had been made by Vail. The port rule was abandoned in favour of a simple circuit closer or key, by which the signals could be formed by hand. For the original pencil-marking method could be substituted any one of three recording methods: a fountain pen (fig. 5), an inked wheel (fig. 6) or a stylus which indented the paper (fig. 7).

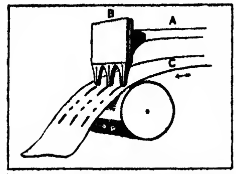

FIG 5 —FOUNTAIN PEN RECORDING

The Sounder.—In April 1844, however, Vail made the valuable discovery that it was possible to read messages by sound. He found that as a dot or dash is recorded the lever makes two distinct sounds, one as it strikes against the stop which limits its motion in one direction and again as it strikes in retreating against the stop which limits its motion in the other direction; when a dot or short line is recorded the interval is shorter than when a long line is recorded, and signals can thus be read by the length of the intervals between sounds. Following upon this discovery the Morse register or recording instrument passed into disuse

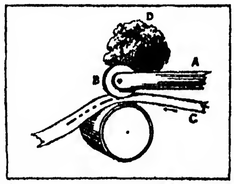

FIG. 6 —INKED WHEEL RECORDING

On April 7, 1838 Morse made formal application for a patent which was granted on Oct. 24, 1848. On Feb. 21, 1838 he had demonstrated his telegraph before the U S president and his cabinet, and a bill was subsequently passed appropriating $30,000 to be expended on a series of experiments to test its practicability. About a year after the passage of the bill an experimental line was completed between Washington and Baltimore, a distance of 40 miles The line was opened for public business and its immense value to the State became apparent; but when Morse offered the telegraph to the Government for $100,000 his offer was refused upon the recommendation of the postmaster-general, as he was "uncertain that the revenues could be made equal to its expenditures." Morse then enlisted private capital and in 1844 a company was organized to erect a telegraph line between New York, Baltimore and Washington By 1851, 50 companies using Morse telegraph patents were in operation in the United States and by 1861 Morse patents were in operation in Europe.

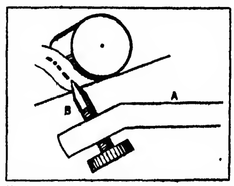

FIG 7 —STYLUS RECORDING METHOD

GENERAL EQUIPMENT

Morse Systems, Circuits and Apparatus.—Many telegraph circuits in various parts of the world still employ the fundamental principles of the original Morse system. Upon circuits of this class, which are operated by the single current method, signals in accordance with the Morse code are transmitted as short and long pulses of current separated by intervals of various lengths during which no current flows. The short and long pulses of current are termed respectively dots and dashes.

Morse Code.—The dot is a very short signal; when made by hand on a telegraph key the lever is depressed for about $\frac{1}{12}$th

of a second. The dash lasts about $\frac{3}{25}$ of a second. These periods of time correspond to 30 average words per minute on land lines. The dot is the unit by which the length of the dashes and spaces are measured. The dash is equal to the length of three dots. The space between components of a letter equals one dot, except in certain dot letters in American Morse which contain a space equal to two dots. The space between the letters of a word is

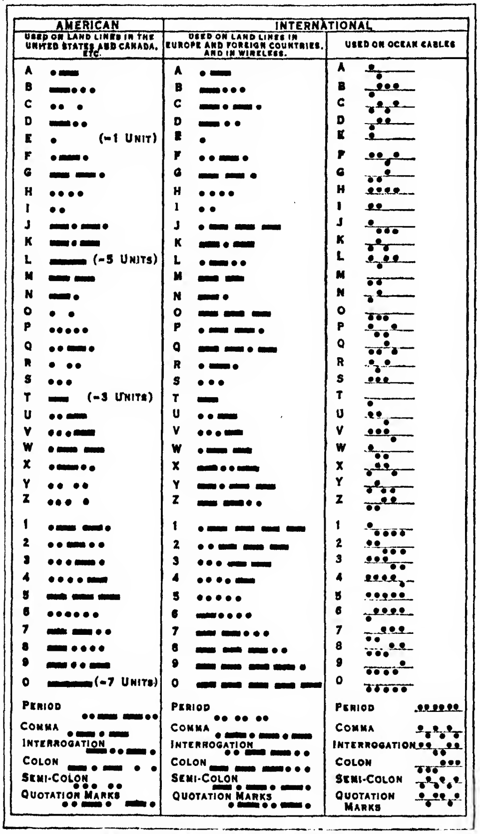

FIG. 8.—ADAPTATIONS OF THE MORSE CODE

equal to one dash. The space between words is twice one dash.

Fig. 8 shows the American and the International adaptations of the Morse code as used on land lines and on submarine cables. The cable code, adapted from the International, employs signals of dot duration only. These short signals are distinguished by their position on a tape; a short signal above the central line corresponds to a dot; an equally short signal below, a dash. On land lines signals are usually received by sound on a Morse sounder; on submarine cables the Kelvin syphon recorder is used. The speed of manual working on land lines ranges from 20 to 40 words a minute, a fair average being 25 to 30 words a minute. On moderately long ocean cables, operated by hand on the syphon recorder system, somewhat similar speeds are obtained.

Various codes of abbreviations are applied to telegraphy, consisting of single Morse letters and combinations of two or more letters that arbitrarily represent figures, words and phrases, to reduce the cost of telegraphing.

In double current operation the current pulses representing the dots and dashes traverse the circuit in one direction and the space pulses in the opposite direction. This is readily accomplished by connecting the negative pole of the transmitting battery to the line for each dot or dash, and the positive pole for each space.

Instruments.—The accompanying illustrations show several kinds of telegraph instruments commonly used on Morse circuits. Plate II., 1, 2 and 3 are keys or transmitting devices, of the three types adapted respectively to closed circuit working as practised on American lines, and to the open circuit method used in Europe and elsewhere. Plate II., fig. 6 shows a modern form of Morse register or recorder; such instruments, however, are now used on comparatively few circuits. Instead of the register, the receiving instrument employed upon nearly all Morse circuits is the sounder as shown in Plate II., fig. 5. The intervals of time between the various clicks and the lengths of the clicks given out by the sounder enable a skilled operator to distinguish the dots, dashes and spaces of the signalling code and thus to read by sound the message being received. On circuits of such a character that the received currents are too weak to operate directly, the register or sounder, a relay (Plate II., fig. 4) may be used to receive the signals and, in responding, to control the application to the register or sounder of suitable power from a local source.

The instruments described and illustrated above are for single current operation. Those used in double current working are somewhat different, the receiving instruments usually being fitted with a permanent magnet to polarize the armature, while the sending instruments have means for reversing the direction of the current instead of merely opening and closing the circuit.

Single Current Working.—The single current Morse system most used in Europe employs an open circuit arrangement, fig. 9, so designated because no current passes over the circuit while it is idle. Sending and receiving instruments are connected to the line at each station, however, and whenever the transmitting key at any station is depressed, a battery at that station is connected to the line and the resulting current causes the receiving instrument at all other stations to respond. American single current Morse circuits are generally operated upon the closed circuit plan (fig. 15) under which current traverses the entire circuit at all times, when the line is idle as well as when a dot or a dash signal is being transmitted. The only periods during which no current flows are those corresponding to the spaces between the dots and dashes, this condition being effected by the opening of the transmitting key at one of the stations. At such times the armature levers of the receiving instruments at all stations are released.

The reading of the received signals and the manipulation of the sending key by the operator are practically the same under both open and closed circuit arrangements. An advantage of the open circuit scheme is its economy in using electrical energy only while signals are actually being sent, but this is offset in many cases by the cost of providing at each station a battery or other

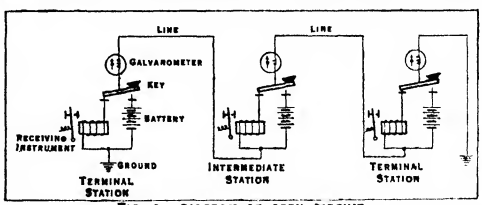

FIG. 9.—DIAGRAM OF OPEN CIRCUIT

source of power sufficient to operate the entire circuit. The closed circuit plan permits the entire power to be supplied at one or two stations, and this advantage generally outweighs the cost of supplying current to the circuit almost continuously, particularly where many intermediate stations are connected. It is not uncommon to have 30 to 40 stations upon one circuit in America.

Double Current Working.—Double current Morse circuits (fig. 11), like those operated by the single current open circuit method, require at each station a source of power capable of operating the entire circuit. The double current scheme has the great advan-

tage over any single current arrangement, however, of operating more reliably, and with less need of readjustments of apparatus, upon circuits of inferior transmission qualities, such as those due to excessive length of line, poor insulation, or the inclusion of long sections of cable.

Duplex and Quadruplex Systems.—In the telegraph systems so far described only one message can be transmitted over

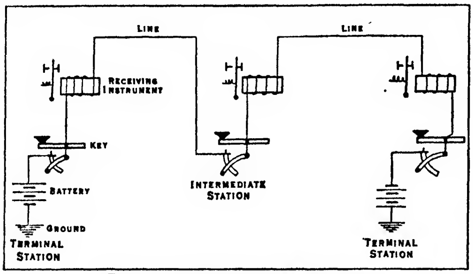

FIG 10—DIAGRAM OF CLOSED CIRCUIT

the line at a time, although the sending may be from any station to any other station as desired. The economic advantages of being able to send two messages simultaneously over one line have led to much invention and development, particularly of duplex systems in which the two sendings are in opposite directions, one from each end of the circuit. The first duplex arrangement was devised by Dr. Gintl of Vienna in 1853 Outstanding developments were made by Frischen of Hanover, who introduced the artificial line in 1854, and by Stearns of Boston, Mass., who improved Frischen's artificial line in 1868 and invented the bridge duplex. Frischen invented the double current duplex in 1863, and this later improvement was taken up and further developed in England by Varley, Heaviside and others, between 1863 and 1872. An essential feature of any duplex system is the provision at each station of a relay or other receiving instrument, so arranged as to be unaffected by any signals sent out from

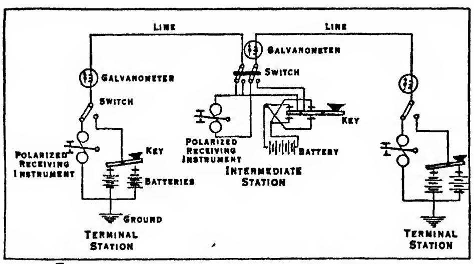

FIG. 11.—DIAGRAM OF DOUBLE CURRENT MORSE CIRCUIT

that station, but fully responsive to all signals received from the distant station.

Artificial Line.—Practically all modern duplex schemes employ the principle of having the signalling pulses of current issue from the transmitting apparatus in duplicate, one pulse going over the line to the distant station and a second identical pulse traversing a branch circuit, known as an artificial line, which is associated with the duplex equipment. To maintain substantial identity between the characteristics of the two sets of pulses, it is important that the artificial line shall closely resemble the real line in the values of, and connections between, its electrical resistance and capacity. With all outgoing signals represented by duplicate pulses of current, the relay or other receiving instrument may be made irresponsive to such signals in either of two ways:

Differential Duplex—In the first method, fig. 12, the electromagnet of the relay is wound with two separate but equal coils or helices of insulated wire. The current going over the line to the distant station passes through one of these coils, while the current which traverses the artificial line passes through the other coil, but in the opposite direction around the electro-magnet to that of the line current. The magnetic effects of the two currents thus neutralize each other, and the result is that the relay is unaffected, just as if no current from the outgoing transmission were passing through either of the coils.

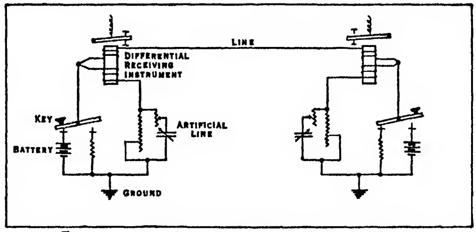

FIG. 12.—DIAGRAM OF DIFFERENTIAL DUPLEX CIRCUIT

In the preceding paragraph it was assumed that the transmitting apparatus at the distant station was applying no current to the line. The effect of such a current application, which occurs whenever a signal is being sent from the distant station, will always be to increase or decrease the strength of the current in the line coil of the relay at the station first considered, without, however, making any great change in the current in the artificial line coil of that instrument. The relay is then operated because of the greater current in one coil than in the other, and thus responds to the signals being received from the distant station. With apparatus arranged in this way at each end of a line, both stations may send to each other at the same time without interference. Because each relay is operated by the *difference* between the currents passing through its two coils, this method of working is known as the differential duplex

Bridge Duplex.—The second method of duplex working in common use employs the principle of the Wheatstone bridge. (*See* ELECTRICITY.) In this plan, fig 13, the duplicate pulses of current for outgoing signals pass to the line and the artificial line, respectively, through equal bridge arms, and have no effect upon the relay or other receiving instrument forming the cross-wire at the extremities of those arms. The relay is, however, responsive to the unbalancing effect of any application of current at the dis-

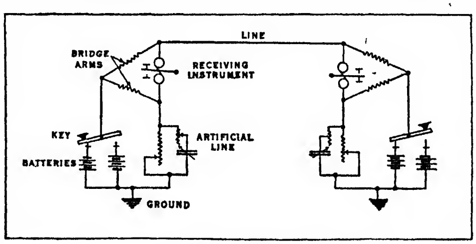

FIG 13.—DIAGRAM OF BRIDGE DUPLEX CIRCUIT

tant station, and thus responds to all signals received from that station.

Quadruplex.—It is possible to operate both differential and bridge duplexes by either single current or double current methods, but in modern practice the double current scheme is generally preferred. By combining a modified single current system with a double current duplex, Edison produced in 1874 the quadruplex. With this scheme four messages, two in each direction, may be simultaneously transmitted over a one-line wire. The two relays at each terminal of the line are arranged to be unresponsive to outgoing signals by either the differential or bridge methods. In receiving signals one of the relays responds only to reversals of

current effected by the distant double current transmitter. The other relay responds only to increases and decreases in current strength, regardless of the direction in which the current is flowing; these variations in the applied power are controlled by a single current key or equivalent means, at the distant station. Fig. 14 is a diagram of a modern quadruplex circuit.

Automatic Telegraphs.—The classification of automatic tele-

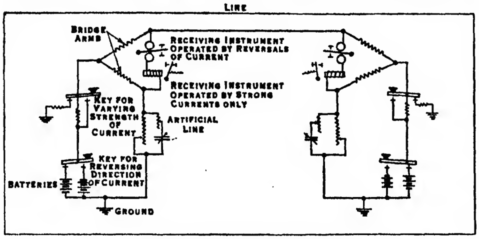

FIG. 14.—QUADRUPLEX CIRCUIT

graphs may broadly include all systems in which signals are transmitted by machine methods and automatically recorded. Automatic means of transmitting and recording had been proposed prior to Morse's invention, and Morse employed them in his first models, but it is only within the last 50 years that printing systems have been used to any great extent.

Between the years 1840 and 1855 a series of instruments was worked out by Wheatstone in England, Froment and Bréguet in France, Siemens in Germany and House in America, with the object of producing a letter-printing instrument, and although these early instruments never came into very extensive use the principles involved are embodied in the modern systems.

The chief advantages of automatic operation of telegraphs are: increased accuracy and greater output with attendant labour saving and cost reduction. The modern automatic systems fall generally into three classifications: (1) signals are recorded in code form and must be transcribed; (2) a facsimile of the original is reproduced; (3) the message is received in printed form.

Recording Systems.—In general, the recording systems employ an automatic transmitter, controlled by a perforated tape, which sends to the line impulses corresponding to a dot-dash code.

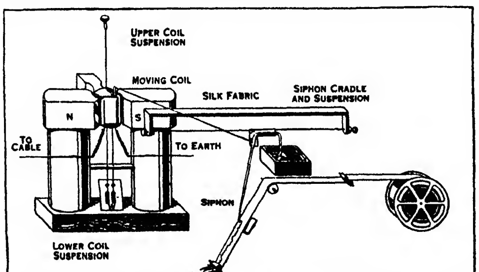

FIG. 15.—KELVIN'S SYPHON RECORDER

These line signals are received and recorded in code form on a moving paper tape. In the Wheatstone system marking impulses are transmitted for long and short intervals to form dots and dashes. An electro-magnet in the receiver forces an inked wheel against a moving strip of paper, drawing an interrupted straight line composed of dots and dashes. This receiver is essentially a refinement of the early Morse recorders.

The recording systems commonly used on older types of ocean cables are developments of ideas proposed by Siemens and Halske, and Lord Kelvin. In these systems the dots and dashes are transmitted as impulses of equal duration but opposite in polarity, while spaces are intervals of no current. The recorder is a galvanometer with an ink syphon attached to the moving coil. The syphon rests against a moving tape, drawing a continuous line which is undulated above or below the centre by deflections of the galvanometer when impulses of dot or dash polarity are received. (*See* fig. 15.)

Various chemical recorders have been proposed by Dyer, Bain, Edison and others and are used to a limited extent. They consist of a metallic wire resting upon a moving, chemically treated tape. The wire and tape form a part of the circuit and when current passes through them an electrolytic decomposition of the wire occurs which causes discolouration of the tape, fig. 16. Signals are usually recorded as long and short lines. The modern transmitters used with these systems are motor-driven mechanical devices arranged so that the perforations in the tape control the motion of levers which actuate contacts, sending the proper impulses to the line. The older types simply permitted a brush to make contact through the perforations with a metallic bed or roller. The perforated tape used for transmission in the above systems is prepared in various types of perforating machines, the more modern of which are provided with keyboards like a typewriter, and are so arranged that the depression of a key will perforate the proper combination of dots and dashes for that character. (*See* Plate I. fig. 5.) The first suggestion for a perforator was made by Bain in 1846.

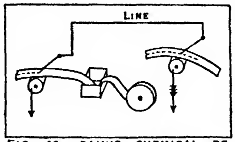

FIG. 16.—BAIN'S CHEMICAL RECORDER

Facsimile Systems.—Among the facsimile systems may be included the writing telegraphs, such as the telautograph invented by Prof. Elisha Gray. (*See* fig. 17.) The transmitter for these systems consists of two rheostats which are varied through suitable linkages by the motion of a stylus. Each rheostat is connected to a separate line wire which terminates through an electromagnet at the receiving end. The armatures of the magnets are connected by similar linkages to a recording pen. As the sending stylus is moved to form a letter the vertical components of the motion are caused to vary one of the rheostats, while horizontal components vary the other, changing the currents in the two line wires. In this way the attractive forces of the two receiving magnets are changed in proportion and the receiving pen is caused to duplicate the motion of the sending stylus.

The more modern facsimile systems are properly regarded as systems of telephotography. They are developments of earlier systems, such as Blakewell's and d'Alincourt's copying telegraphs and the Casilli pantelegraph. (*See* Plate I. fig. 4.) In these systems the picture is specially prepared for transmission by a photographic process and then exposed, a minute area at a time, to a transmitting device by means of which the line current is

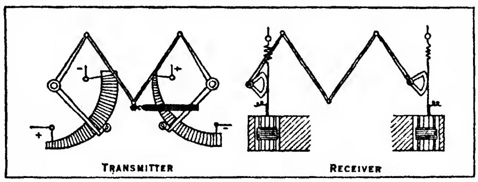

FIG. 17.—GRAY'S FACSIMILE SYSTEM

varied proportionately with the degree of shading in the exposed area. At the receiving end equivalent minute areas of a sensitized paper are synchronously exposed to discolouration, the degree being controlled by the variations in line current, thus duplicating the contrasts of the original picture. Among the systems now in use may be mentioned those developed by the American Telephone and Telegraph Company, The Radio Corporation of America, and Siemens and Halske, together with the Bartlane, Belin and Ferreegraph systems.

Printing Telegraphs.—Many of the early printing telegraphs were developments of the step-by-step principle as incorporated in present-day stock quotation tickers. Printers operated by this

principle are provided with a rotatable type-wheel upon which the characters are evenly spaced around the periphery. This type-wheel is provided with a stepping device, operated by an electro-magnet and so arranged that each impulse received from the line will rotate the type-wheel one character. Assuming that the initial position and arrangement of the type-wheel are known, the sending operator may transmit a sufficient number of impulses to move any desired character into the printing position When

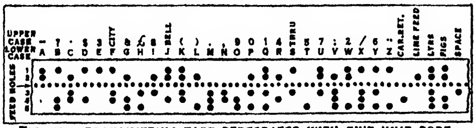

FIG. 18.—TRANSMITTING TAPE PERFORATED WITH FIVE UNIT CODE

this has been done, an impulse of a different character is transmitted which energizes a print magnet to make the impression These systems are commonly provided with an automatic keyboard transmitter containing a motor-driven commutator which, in the interval between the depression of any two keys, will send the required number of impulses to move the type-wheel from its previous position to the character corresponding to the key next to be depressed. The most important improvement of this principle was contributed by Hughes, who materially speeded up the system by causing the sending and receiving apparatus to maintain constant synchronism. Line impulses were transmitted only for the purpose of making an impression when the type-wheel reached the desired position. Other improvements were contributed by Phelps, Wright, Burry and Scott.

The majority of the modern printing systems make use of the Baudot or five-unit code. In these systems five impulses, any one of which may be either selecting or non-selecting, are transmitted for each character. With such a code it is possible to obtain 31 different combinations, 26 of which are assigned to the letters of the alphabet, leaving five for functions such as line feed, space, etc. (fig. 18). The five impulses making up the code are sent to the line, successively, by means of a rotating distributor or commutator, and are distributed at the receiving end, by means of a similar device, to five receiving magnets These magnets, through any one of several selecting mechanisms, determine which one of the characters of a typewriting machine is to be printed In order that the first impulse may operate the first receiving magnet, etc., each magnet must be connected with the line while the corresponding impulse is being transmitted, *i.e*, the sending and receiv-

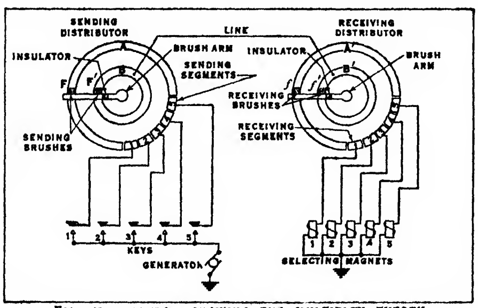

FIG 19—DIAGRAM SHOWING THE MULTIPLEX THEORY

ing distributors must rotate in synchronism. This is accomplished in several different ways with different systems. In some, extra impulses are transmitted for this purpose, while in others the signals themselves are used. The printers used in connection with these systems are arranged to record the message on a page in final form for delivery (fig. 23) or to record on a gummed paper tape which is pasted on a blank by the receiving operator (*See* Plate I., fig. 8.)

Various methods of transmission are used with these systems: one involves the use of five keys which must be set up in their various combinations by the operator; another employs a direct keyboard like a typewriter, each key acting upon five transmitting keys to set up the combinations. The most common method uses a keyboard perforator which prepares a paper tape to be sent through an automatic transmitter. (*See* Plate I. fig. 3). The perforations in the tape actuate five key levers in the transmitter.

Among the printing systems—exclusive of multiplex—employing the five-unit code (Plate I. fig. 6) may be mentioned the Murray, Morkrum, Kleinschmidt, the Siemens and Halske and Creed systems. Other printing systems have been developed by Buckingham, Creed and Barclay, which use the dot-dash code.

Multiplex Methods.—It is possible, with the printing systems employing synchronous distributors, to provide additional transmissions or channels of communication. This is accomplished by dividing the use of the line between the several channels, the distributors being made use of for this purpose. The multiplex principle may be illustrated by fig. 19, which shows a sending and receiving distributor, the brushes of which are rotated in constant synchronism and phase The sending distributor is provided with five segments to which are connected five keys, which may be operated manually or by automatic means, to set up the five-unit combinations of the Baudot code. Five corresponding segments on the receiving distributor are connected to the five selecting magnets of a printer. Assuming that a combination corresponding to the desired character has been set up on the transmitting keys, signals forming this combination will be transmitted to the line as the sending brushes pass over the sending segments. At the instant when the sending brush is in contact with the first sending segment the receiving brush will be in contact with the first receiving segment; and if No. 1 key is in an operated position the circuit will be completed and the first selecting magnet will be energized As the sending brushes pass to the succeeding segments the remaining selecting magnets will be operated or remain inoperative, depending upon the position of the corresponding key at the sending station; thus in each revolution an entire character is transmitted by the transmitter and received by the printer. While the diagram illustrates only one channel of communication it is obvious that the section of the rings *A* and *A'* between segments 5 and 1 may be provided with additional groups of five segments which can be connected to other sets of keys and selecting magnets to provide additional channels of communication. The character of transmission is such that duplex methods may be applied to permit simultaneous operation in both directions This principle is widely employed and the modern multiplex systems ordinarily provide from two to five separate transmissions in each direction simultaneously. These systems are usually designed for a maximum speed of about 360 letters per minute per channel, that being considered as the maximum speed at which operators can economically work for extended periods

Multiplex methods were first introduced by Farmer in America. He suggested the division of line time between two or more operators Myer and Delaney endeavoured to improve the system, but it was Baudot who developed the first practical multiplex printing system using the five-unit code. This system has become the basis of the other modern multiplex systems, such as the Murray, American and Morkrum multiplex systems. Multiplex systems developed by Rowland and Potts employ eleven and eight unit codes, respectively.

The growth of automatic telegraphy has been particularly rapid during the past 20 years. Practically all ocean cables are operated by automatic methods and approximately 70% of land line traffic in America is handled by printing systems.

Repeaters.—All telegraph circuits are subject to certain transmission difficulties which limit the length of line over which direct working is practicable. The resistance of the line conductor and its imperfect insulation tend to reduce the strength of the current available to operate the receiving instruments. In addition, and what is frequently of greater importance, the current pulses representing signals are distorted from their original form by the electrostatic capacity of the line conductor and any inductance, such as that of the electro-magnets of instruments in the

VIEW OF AUTOMATIC TELEGRAPH PRINTING MACHINE

1. Western Union Simplex Printer consisting of an electrically operated typewriter with standard keyboard. Messages transmitted and received are printed on a gummed tape. In received messages the tape is first passed through a specially devised moistener before it is affixed to a regular telegraph blank

2. View of the same Western Union Simplex Printer with the cover removed and showing the mechanism of the machine. The electric motor at the top operates the keyboard

circuit (see *Theory of Transmission* below). Because of these difficulties it is the practice to break up long telegraph circuits into two or more sections, each of which is relatively easy to operate. These sections are then connected together by repeaters which receive the signals from one section and automatically retransmit them into the next section.

Morse Circuit Repeaters.—A very simple form of repeater consisting of only two relays may be used in single-current open-circuit working. Each of the two lines is connected through the contacts and armature lever of one relay to the electro-magnet coils of the other relay. When a pulse of current representing a signal is received over either line the electro-magnet of one relay is energized and its armature lever, in responding, applies a battery or other source of current to the other line, thus repeating the signal into the latter.

For closed-circuit working a more complex arrangement is necessary in order to avoid the tendency of each relay to repeat signals back into the line from which they were received. This interference is overcome by interlocking electro-magnetic devices.

To facilitate adjustments many repeaters employ additional relays or transmitters to control the circuit into which signals are being repeated, thus relieving the receiving relay in each case of any duty other than the control of such a transmitter.

Duplex Repeaters.—The repeating elements of duplex repeaters are very similar to those of open circuit Morse repeaters, usually comprising a receiving relay for each of the two line sections. This relay, either directly or by means of a transmitter which it controls, re-transmits into the other line section the signals by which it is operated. An artificial line must be provided for each of the two sections of line connected to the repeater, and each relay must be arranged differentially or in accordance with the bridge method so as to respond only to incoming signals. Various auxiliary devices are also required to permit observation of the passing signals in both directions by an attendant and to facilitate necessary readjustments of the apparatus.

Regenerative Repeaters.—Recent years have witnessed much development of regenerative repeaters by which the signals are not only repeated with renewed power but are also corrected and reformed, so that they leave the repeater with all the characteristics of the original signals, or, in some cases, with even better qualities than in the initial transmission. The general principle upon which regeneration is based is to select from each received signal a small portion—usually near the centre of the time interval occupied by the signal unit—which is most likely to be of full strength and free from imperfections. By using this fraction of the signal to operate a relay and other mechanisms which control the pulses to be applied to the outgoing line, the re-transmitted signal can be made practically perfect.

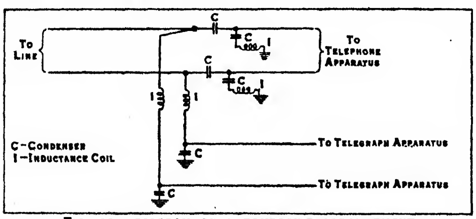

FIG. 20.—DIAGRAM OF A COMPOSITE ARRANGEMENT

Simultaneous Telegraphy and Telephony.—Two methods are in extensive use for superposing telegraph circuits upon wires already arranged for use as telephone circuits.

Composite Method.—In the composite arrangement (fig. 20) two ground return telegraph circuits are obtained from the two wires forming a metallic return telephone circuit. This is accomplished by taking advantage of the facts that a condenser offers little impedance to the alternating currents of relatively high frequency which operate the telephone, but is an almost impassable barrier to the much slower changes of current used in telegraphy, and that an inductance in the form of an electro-magnetic coil can be so constructed that it will oppose greatly the flow of the telephone currents but will readily pass the telegraph currents. By forming a network of such condensers and inductances an electrical filter is obtained which guides the two classes of currents into their proper channels for the operation of the telegraph and telephone apparatus.

Simplex Method.—The simplex method of superposing permits only one ground return telegraph circuit to be operated over the two wires used to form a metallic return telephone circuit. In a common form of simplexed circuit (fig. 21), a repeating coil or transformer (*see* ELECTRICITY) is interposed at each terminal between the telephone apparatus and the line. The winding of this transformer, which is connected to the line wires, is tapped at its centre and this tap is connected to the telegraph apparatus. By this arrangement the telegraph currents are divided, one-half passing over each of the two line wires. These currents produce no effect upon the telephone apparatus because in dividing at the centre tap of the transformer winding the two equal parts must pass around the core in opposite directions and thus neutralize each other's magnetic effects. On the other hand, the alternating currents of the speech transmission so traverse the line windings of the transformer as to cause the maximum magnetic effect, and are thus repeated to the telephone apparatus.

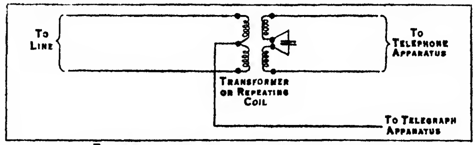

FIG. 21.—DIAGRAM OF THE SIMPLEX CIRCUIT

Carrier Currents.—In recent years it has become practicable to increase greatly the traffic capacity of certain classes of telegraph circuits by the use of alternating or pulsating currents of different frequencies for each message channel operated. In systems employing this principle each transmitter controls the application to the line of current at a certain frequency. At the receiving station the complex line current composed of these numerous components is passed through electrical filters, each of which excludes all other frequencies and delivers to the receiving instruments only the signals represented by the particular frequency assigned to that "channel." As many as 10 to 12 channels are often obtained on one metallic circuit by this means.

Subsidiary Systems.—Most telegraph administrations have established methods of distributing time signals to facilitate setting clocks and other timepieces in agreement with some recognized standard of correct time. In the United States one of the telegraph companies distributes over a very extensive network of circuits the "noon signals" furnished by the Naval observatory at Washington. These signals are used to check the operation of master clocks of great accuracy and reliability in all the principal cities. The master clocks in turn control the operation of large numbers of transmitting instruments which send out hourly synchronizing impulses to over 115,000 electrically driven clocks.

Another adjunct to commercial telegraph service for which wide use has been found is the provision of means whereby a patron may readily summon to his place of business or residence, a messenger who will carry to the nearest telegraph office any messages which the patron may desire to have transmitted. Over a quarter of a million "call boxes" for this purpose are provided by one system in the United States. Each call box is essentially an automatic telegraph transmitter which, when operated by the turning of a crank, sends to the telegraph office code signals which identify the patron to whom the box is assigned. These signals are received upon a Morse ink-writing register and in response a messenger is promptly started for the office or residence indicated as the source of the call. The circuit arrangements are characterized by ingenious devices which ensure the reception of the signal even under very adverse conditions due to faults upon the line conductors used.

AUXILIARY EQUIPMENT

Central Office Equipment.—In any large telegraph system it is necessary to concentrate the operating equipment at certain points in what are called central offices. These act as clearing houses for a definite area, collecting all the business from that area and despatching it to destination. Such offices vary considerably in size, the variation being dependent on the area served and the volume of traffic that such area produces, ranging from one small operating room to the 155,000 sq ft of operating space in the new Western Union building in New York. Special attention must be paid to the design of central office buildings. The operating rooms must be in large units and be adequately provided with light and air Properly designed illumination is a large factor in increasing the speed and accuracy of operators, and, owing to the inevitable concentration of workers, the condition of the air is important. The greater part of a central office is taken up with operating rooms (*See* Plate II) In the smaller offices it is usual to collect all the operating equipment in one room, but where the size of the office prohibits this, the equipment is divided according to its method of operation. Thus those circuits which are manually worked, with a key and sounder, will be found on one floor, multiplex circuits will form a second group and short-line printer or simplex a third. Furthermore, the building must provide quarters for switchboard and testing equipment, for the service department—which deals with questions of accuracy, obtaining better address, etc, after a message has been sent—and for rest rooms and lavatories for the operators

Power Supply.—The power required for the operation of telegraph circuits is divided into *local* and *main line,* the former supplying the current which operates all the local circuits of Morse and automatic sets, and the latter that which goes out over the lines to the distant station. The local power in any one office is a fixed potential, but the main line power must be of two or three different voltages to satisfy the various requirements of the circuits In a very small office, where the power demands are slight, and usually of only one voltage, primary batteries are in some cases used This type of battery was widely employed in the past, but is now rapidly becoming obsolete. Much more general is the use of storage batteries, which in some countries are used to supply telegraph power for the largest offices They have the advantages of complete reliability and steady voltage. In the United States, the general practice is to use motor generators in all but the smaller offices Power is purchased from the local supply company and is converted to the potentials required. If the local supply is direct current and is sufficiently steady and free from interruption it may be used directly and booster sets installed to give such variations in voltage as are necessary. If the local supply is subject to frequent interruptions storage batteries are customarily employed. Three main line voltages are provided in the Western Union system, 110, 160 and 240 volts, with separate machines for positive and negative current and a third, reserve, machine at each voltage These machines have been specially designed to give constant voltage under all load conditions, a result obtained by using compound-wound machines with a flat-compounded series field Motor generators have the advantage over storage batteries of requiring less space and costing less to maintain. To guard against temporary failures of the main source of supply an emergency supply is always furnished This may take the form of a storage battery or may be a generator set driven by a gas or gasolene engine. The emergency engine generator must be sufficiently large to provide all the telegraph power required and also to maintain sufficient lights to enable work to be carried on and, in some cases, to keep running essential services such as message conveyors and pneumatic tubes. In some offices a storage battery has been provided to take care of the interval between the failure of the main power and the starting of the emergency engine.

Switchboards.—All the telegraph wires which enter an office are grouped in a switchboard which also accommodates conductors to all the telegraph apparatus in the office This switchboard (Plate I. fig. 2) is usually a collection of jacks arranged in groups or singly. Each jack or group of jacks is connected to one line wire or one operating set and the two are joined by plugs and cords. Line wires and wires to operating sets do not terminate directly on the switchboard, but instead go to a distributing frame (Plate I. fig. 1) placed immediately behind the switchboard. The distributing frame has connecting blocks in vertical rows on one side and in horizontal rows on the other. On the vertical side are all wires from the outside and from the operating sets. The horizontal side has permanent connection with all the jacks of the switchboard The two sides, vertical and horizontal, are joined by cross-connection wires which may be rapidly changed if required. Normally, each particular wire is assigned to some particular set. If a temporary change is necessary owing to the failure of a set or a wire it is made by means of the plugs and jacks on the switchboard. If the change is to be permanent it is made on the distributing frame by moving the cross-connecting wire. On the front of the switchboard is a shelf which is equipped with the necessary apparatus for testing wires and locating faults, consisting of a Morse set and plugs and a volt-milammeter for the former and a Wheatstone bridge set for the latter. Records are kept at the switchboard of all the outside lines connected to it, their length, the route they follow and the material of which they are made. Periodical measurements are made of the resistance of each line and recorded on a special form If a fault develops in any circuit the attendant can determine at once if it lies inside the office, at the switchboard or in the set, or outside on the line. If the latter, he can discover by means of the volt-milammeter the nature of the fault (*open, cross* or *ground,* etc) and with the Wheatstone bridge the location of the fault.

Grounds and Protection.—Telegraph operation is almost always carried on by means of an earth return, *i.e*, one wire only runs between the two points and the electrical current returns by way of the earth This feature makes it imperative that each telegraph office be provided with a good *earth* or *ground.* The requirements are that the resistance shall be low—for the larger offices not more than 1 ohm—and the connection as direct as possible A public water-supply system, with its large quantity of metal piping laid in the soil, offers the best ground and is always used where available Gas pipes are nearly as good but their use is attended with the risk of a spark igniting an escape of gas Where neither water nor gas are attainable *made* grounds must be constructed by sinking iron pipes or metal in the earth Made grounds are never as satisfactory as water or gas pipe grounds owing to the smaller areas of contact. Connection is made to the ground by means of large size rubber-covered wire. run without splices, kinks, coils or sharp bends. These last considerations are important from the point of view of the protection of the office from lightning and other electrical currents that may come in contact with the wires and cables entering the building Before being carried into the switchboard each wire is provided with an arrester and fuse The arrester consists of two small carbon blocks separated from each other by only a few thousandths of an inch of air, one side being connected to the line and the other to earth Fuses are placed in the line to prevent a foreign current, which may have been picked up by the outside wire or cable, from damaging the instruments in the office The arrester limits the voltage that can reach the wiring or apparatus by diverting to earth potentials that would injure the apparatus or wiring or the employees.

Message Conveyors.—In any central office means must be provided for carrying messages between different parts of the room A message received on a wire in one corner may be sent out again on a wire in another corner and a rapid method of transference is necessary. The messages are conveyed mechanically from the operating tables to a distributing centre, where they are sorted and sent out on other conveyors to different sections of the room. Many types of conveyor are in general use, moving belts being the most common. The main considerations are speed and accessibility, with all features eliminated that would tend to lose, mutilate or delay a message. Belts are run at speeds of from 200 to 250 ft. per minute. Other types of conveyors have been developed with speeds as high as 500 ft. per minute. The distributing centre is the focal point of the

operating room and is placed in a central position. Pneumatic tubes (*q.v.*) are also widely used both for carrying business within the confines of an office and for connection with other offices near by.

Telegraph Wires and Cables.—The conductors necessary to establish connections between various telegraph offices consist either of bare wires supported overhead on poles, or of groups of insulated wires held together by a common covering or sheath, to form cables. Cables may be carried overhead on poles or they may be laid underground. Overhead lines constitute the larger portion of the plant used to connect offices in one town with those in another town, although the use of cable is increasing rapidly. Connections between offices in the same town, and between offices and patrons, generally require the use of underground cable, since space is usually not available in towns for overhead wires or cables.

In general, bare wires consist of hard-drawn copper, although galvanized iron wire has been used quite extensively, and bronze wire is now being tried out with considerable success. The advantage of copper for line conductors is its high conductivity. Iron wire, while cheaper than copper, corrodes more rapidly except in dry climates and is not suitable for long or high speed circuits, because of its high resistance. Bronze wire is stronger than copper and less subject to mechanical injury, but its resistance is somewhat greater and it is slightly more expensive than copper. The copper wire ordinarily used for overhead telegraph lines has a diameter of 0·114 in. and weighs 210 lb. to the mile. Other sizes of copper wire are employed to a limited extent, the largest having a diameter of 0·165 inch. The most common size of iron wire used to-day has a diameter of 0·165 in. and weighs 380 lb. to the mile.

Conductors in cables designed for telegraph service are of soft-drawn copper varying in diameter from 0·036 in. to 0·102 inch. Ordinarily, cable conductors are separated and insulated by means of paper wrapped spirally about them, although cables having rubber-insulated conductors are often used for short distances. The insulated conductors are arranged in pairs, which consist of two conductors twisted together or in quads each consisting of two pairs twisted together. These pairs or quads are arranged compactly in layers. Paper-insulated conductors are always enclosed in a lead sheath $\frac{1}{8}$ in. in thickness; rubber-covered conductors may be enclosed either in a lead sheath or in a covering of heavy braid. The number of conductors provided in telegraph cables varies, the largest now in common use being 404 pairs of paper-insulated conductors 0·036 in. in diameter. The outside diameter of this cable is $2\frac{5}{8}$ in. and the weight is $7\frac{3}{4}$ lb. per foot.

Overhead Lines.—Poles used to support wires and cables are usually of wood, although steel and concrete poles have been used. They are of such height as to provide a suitable clearance from the ground for the wires and cables. The size of poles required and the distance they are placed apart depends upon the geographical location of the line and upon the number of wires and cables carried. Lines situated in sections of the country where ice or snow is apt to collect upon the wires require the use of larger poles placed closer together than lines in portions of the country where ice never or rarely forms. In more favourable climatic locations and if only a few wires are supported poles are often placed 175 ft. to 200 ft. apart. It is not considered in general good practice to place more than sixty wires on a pole line, although eighty or even a hundred wires are sometimes carried for short distances where it is not too expensive to place the poles close together.

It is common practice to impregnate wood poles used in telegraph lines with some form of preservative in order to retard decay. Until recently creosote was used almost exclusively as a preservative for poles, but certain insoluble arsenic compounds are now employed extensively. (*See* Timber Preservation.) Bare wires are supported on insulators usually made of glass and held in position by wire ties. These glass insulators are mounted on either wood or steel pins which are set vertically in crossarms of wood.

Crossarms are normally 10 ft. in length and accommodate ten pins spaced approximately 12 in. apart. For lines carrying a small number of wires 6 ft. crossarms carrying six pins are often used. These crossarms are securely fastened to the pole, the top one approximately 12 in. below the top of the pole and additional arms each 2 ft. below the next higher arm. Cables when placed on poles are supported by suspension strands, consisting of seven high-strength galvanized steel or bronze wires twisted together. The weight of the cable to be supported determines the strength of suspension strand used, the heavier cables requiring strands having a maximum strength exceeding 18,000 pounds.

Cables are hung from suspension strands by means of metal rings clamped on the strands from 1 to 2 ft. apart. The suspension strands are fastened to the poles by means of strong metal clamps bolted to the poles. At corners, along curves, and at the ends of lines, it is often desirable to strengthen the line by the use of guys of steel strand similar to that used for supporting cables. These guys are fastened at the upper ends to the poles and at the lower ends to logs or other substantial objects buried in the earth. The purpose of these guys is to prevent the poles from being pulled over or broken by the constant pull of the wires.

Underground Construction.—Where cables are placed underground some form of conduit, with independent duct space for each cable, is usually employed to permit the cables to be readily installed and removed. The ducts are usually of hollow tile, creosoted wood or fibre. Iron pipe is used in special situations. All ducts are 3 in., or slightly more, in diameter. The conduit is buried to a depth of at least 2 ft. in the ground. As the length of cable which can be pulled through a duct is limited, splicing chambers or manholes are provided at intervals of 500 ft. to 600 feet. Manholes are normally at least 3 ft. wide, 5 ft. long and $4\frac{1}{2}$ ft. deep, although in many cases considerably larger sizes are required. They are usually constructed of brick or concrete with a removable cover.

Cable is pulled into conduits one length at a time and then the ends are spliced together. In splicing paper-insulated cables a foot or more of the sheath is removed from the end of each of the cables to be spliced, and a few inches of the insulation is removed from the conductors. The conductors are then joined by twisting, soldering or other means, and the joints are insulated by being covered with small paper or impregnated cotton tubes. After all conductors are joined the splice is wrapped with strips of muslin and a lead sleeve is slipped over it. This sleeve is sealed at each end to the cable sheaths by means of wiped solder joints.

At points where overhead wires connect to paper insulated cables, it is usually necessary to provide electrical protection to prevent high voltages, due to lightning or to accidental contact with power wires, from puncturing the insulation of the cables. Accordingly arresters similar to those used in offices are commonly placed on poles, at which junctions between wires and cables occur. Where large currents are apt to result from contact with power wires, fuses are also used to prevent the cable conductors from being burned out. Protector equipment is usually housed in boxes mounted on the junction poles.

THEORY OF TRANSMISSION AND INTERFERENCE

Transmission.—The fundamental requirement of a telegraph system is a source of energy controlled in accordance with the code and the characters to be transmitted, which sends sufficient energy through a line wire to operate a suitable receiving or recording device at the distant end. Where some interference is present, as is usually the case, the received energy must be sufficiently greater than the interference to enable the signal to be distinguished. The sending source of energy usually consists of a direct current battery or generator, under proper control. From what follows, however, it will be evident that the transmission of telegraph characters requires the use of apparatus and lines capable of transmitting sine wave alternating currents of various frequencies, *i.e.,* a band of frequencies, within a certain range. A communication circuit of any kind is thus fundamentally different from a circuit for transmission of energy for power or lighting, in which

direct current or alternating current of only a single frequency need be transmitted.

In a telegraph system the signals sent, of course, are continually changing in character, and there will be times when several consecutive dots or reversals are sent at the highest fundamental frequency of transmission for the given circuit. The number of such complete reversals per second may be spoken of as the *fundamental signalling frequency* or the *dot frequency.* Common fundamental signalling frequencies for various circuits are tabulated below.—

Messenger call circuits .	2 cycles per sec.
Key operated Morse	6 to 18 „ „ „
Automatic telegraph systems	15 to 60 „ „ „
Submarine cables, non-loaded	4 to 15 „ „ „
Submarine cables loaded	30 to 80 „ „ „

The alternating current characteristics of signal combinations may be most readily considered by examining a number of typical combinations of signals, such as in fig. 22, the combinations being assumed to repeat themselves again and again Such combinations may be analysed by the ordinary Fourier method into a series of sine wave components Analyses of a considerable number of these recurring combinations show that all frequencies from zero to infinity—excluding even multiples of the fundamental signalling frequency—are present in the transmitted signals In order to operate a receiving instrument at the distant end, it is not necessary that all of the above frequencies be transmitted through the line In a submarine cable system, which ordinarily is operated quite efficiently, it is usually sufficient to receive frequencies from zero up to about 1·6 times the fundamental signalling frequency. Since the higher frequencies are more difficult to transmit through the line this condition facilitates operation. In a land line telegraph system operated with less complex equipment it is preferable that frequencies from zero to about three times the fundamental signalling frequencies be received.

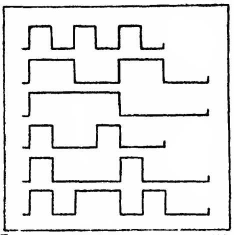

FIG 22 — EXAMPLES OF RECEIVING SIGNALS

The voltages and currents originating at the transmitter may be modified by any impedance at the sending end of the line, by the line itself, and by the receiving equipment The effect of the line is ordinarily to reduce the amount of higher frequencies transmitted, thus limiting the speed of transmission. This is particularly true in the case of the submarine cable, in which frequencies in the neighbourhood of the fundamental signalling frequency are received with only a small fraction of the magnitude of frequencies much lower than this value. In order partly to counteract this difference a condenser is customarily placed in series at the sending end of a submarine cable, thus reducing the magnitude of the lower frequencies and thus reducing distortion of the received signal. Various special devices are used at the receiving end of such a cable for the purpose of strengthening the higher frequencies and reducing lower frequencies in order to reduce distortion.

In order to decrease the loss of signalling energy in the line its inductance may be increased by artificial means known as *loading*. This is especially successful with long submarine cables The effect of the inductance is particularly to sustain the higher frequencies. The velocity of propagation is decreased, and the signal, arriving slightly later, is received with much increased energy.

Interference.—Telegraph operation is more or less affected by parasitic currents from various outside sources. These sources include: (1) earth potentials arising from natural causes (*see* MAGNETISM); (2) earth potentials arising from electric railway systems; (3) induction from one telegraph circuit to another; and (4) induction from electric railway or power supply systems. The relative susceptiveness of the several forms of telegraph operation is as follows, expressed in order of decreasing

	Miles of telegraph wire	Telegrams sent ('000s omitted)

susceptiveness: (1) submarine cable; (2) quadruplex; (3) multiplex; (4) duplex; and (5) single Morse. Because of the extensive use of multiplex telegraphy interference with circuits of that type is by far the most serious. Small amounts of potential from extraneous sources result in impairment of the maximum speed at which these circuits may be operated; large amounts render the circuits inoperative. With extremely high potentials persons operating the circuits may suffer bodily injury, or property dam-

age may result. To mitigate the interference from these parasitic currents various means may be applied to the telegraph circuit or to the source of the interference, if this be an electric railway or power supply system. In application to telegraph circuits these mitigative devices may take the form of impedances whose function is to filter out the extraneous current, or of transformers or generators whose function is to interpose in the circuit a potential to counteract that from the outside source. In application to electric railway or power systems, impedances inserted at appropriate points, selection of proper transformer connections, favourable operating methods or transpositions may often be advantageously employed to reduce the inductive influence of the interfering system. Sometimes, however, an increase in the physical separation between systems is the only practicable remedy.

Telegraph Statistics.—The tabulated statement on p. 890 shows the telegraph wire mileage of the world and the number of messages transmitted. The wire mileage in all cases, except where otherwise indicated, is as of Jan. 1, 1927, and the number of messages transmitted is for the year 1926, except in the cases of Brazil, Ecuador, Paraguay and Guatemala, for which countries statistics for 1926 are not available. In the cases of a few countries there are no statistics of telegrams transmitted, and the space for such statistics in the table is left blank.

SUBMARINE TELEGRAPHY

History.—Although suggested as early as 1798 by the Spanish scientist Salva, and made the subject of several experiments in the early part of the 19th century by Morse, Wheatstone and others, which demonstrated the possibility of submarine telegraphy, it was not until the introduction of gutta-percha as an insulator and the invention of a machine for applying it to wire, that the submarine cable became commercially attractive.

In 1850 a cable was laid between England and France, but it was broken shortly after communication was established because of its inherent physical weakness. The addition of galvanized iron armour wires, wound with a long spiral lay on a cushion of jute yarns around the central gutta-percha-covered copper conductor, contributed the necessary strength when the next attempt was made in 1851, and this cable, between Dover and Calais, proved successful. In the next few years a number of cables were laid between England and adjacent shores, between Denmark and Sweden, and in the Mediterranean. The first attempt to lay a cable across the Atlantic in 1857 ended in failure when the cable broke at a depth of 2,000 fathoms. In the absence of any means of recovering the end the project had to be abandoned. In Aug. 1858 a cable was successfully laid between Valentia, Ireland, and Hearts Content, Newfoundland. This was operated for about three months, when it became interrupted in deep water and could not be repaired. In the years 1865 and 1866 two more cables were

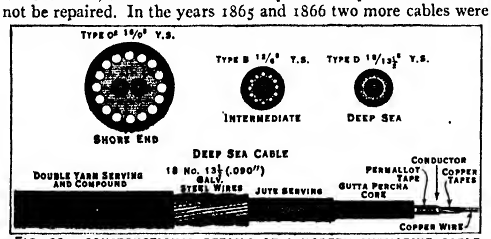

FIG. 23.—CONSTRUCTIONAL DETAILS OF A MODERN SUBMARINE CABLE

laid; the first broke when about two-thirds laid, but the second was successfully laid, and soon afterwards the end of the 1865 cable was picked up with difficulty and its laying was completed.

These cables, with which the names of the American financier, Cyrus Field, and the British scientist, Lord Kelvin, are closely associated, were operated by the Atlantic Telegraph Company without competition until 1869, when the French Atlantic Telegraph Company opened a cable for traffic. With the success of the Atlantic cables established, the growth of submarine cable systems was rapid until at present (1929) there are 21 cables across the Atlantic between North America and Europe alone, and there is a total of about 3,500 cables in the world, with an aggregate length of over 300,000 miles.

It was early realized, even before the first Atlantic cable was laid, that a very sensitive instrument would be needed for the reception of signals on long cables. The mirror galvanometer, invented by Prof. William Thomson, later Lord Kelvin, filled this need for many years. The syphon recorder invented in 1867, which had the advantage of leaving a written record, gradually replaced the mirror galvanometer, and in its improved form is still largely used on long cables. In 1871 the duplex system was introduced, permitting simultaneous transmission of messages in both directions, and the speed of operation has been gradually increased from the initial 15 letters per minute of 1858 to the successful transmission of upwards of 2,500 letters per minute in recent years, while the rate charged dropped from a minimum of about $100 per message to a maximum, between New York and London, of 25 cents per word.

Construction.—Fig. 23 shows the constructional details of a modern submarine cable. The conductor is made of copper, stranded or having a central wire surrounded by strips wound spirally. Over this is moulded the insulation. Some of the shorter cables have made use of india rubber as an insulator, but although progress has been and is still being made to develop substitutes, gutta-percha remains the best material for the purpose.

The operating characteristics of a cable depend upon the size of the conductor and the thickness of the insulating wall. Some of the very recent cables are loaded by means of a thin ribbon or thread of highly permeable nickel-iron alloy wound around the copper conductor, which has the effect of greatly increasing the speed at which the cable can be worked. To protect the insulation against injury by marine borers, such as the teredo worm, a brass tape is wound around the gutta-percha on all cables except those lying in very deep water. Next comes a filler of jute yarns which acts as a cushion for the armour or sheathing wires. These are wound on with a long spiral lay. For cables used in the deeper portions of the ocean it is the practice to use galvanized steel wires of high tensile strength, and as the depth of water decreases the steel wires are replaced by galvanized wrought iron wires of larger size. As the cable approaches the shore the armouring is made heavier until at the shore it is doubly sheathed. This added protection in shallow water is necessary to prevent damage by ships' anchors, trawling gear, rocks and, in northern latitudes, icebergs. An outer double wrapping of tarred jute yarn, or tape steeped in a compound of tar and pitch, preserves the armour from corrosion. So efficacious is this covering that lengths of cable have been picked up in deep water after more than 40 years of continuous submersion with the jute wrapping and compound still adhering to the armour wires, the latter being to all intents and purposes as good as ever. In addition, extra protection is now given to deep-sea armourings by taping each individual armour wire. The outside diameter of the ordinary deep-sea type of cable is about 1 in., and the weight in air about two tons per nautical mile. The shore-end types run as large as 3½ in. in diameter and weigh as much as 30 tons per nautical mile.

Cable Laying.—It is the usual practice for the manufacturer to lay the cable and test it to ascertain whether the specified electrical characteristics have been met before turning it over to the operating company. The ships used for laying are specially constructed to carry cable in cylindrical tanks which are built into the ship's structure. The largest ship of its kind, the C.S. "Dominia," owned and operated by the Telegraph Construction and Maintenance Company, to which reference was made in the preceding paragraph, has four of these tanks, with a total net coiling capacity of 190,000 cubic feet. In them may be stowed away a cable over 3,000 m. long. The cable is coiled down around a central hub-shaped cone in horizontal layers, starting at the tank wall and coiling in toward the centre. When the cone is reached the cable is run out radially to the wall, again with wedge-shaped strips of wood, called "feather-edges," on either side to protect it from the weight of the layers above, and the process is repeated. When paying out the cable it is pulled through a circular hatch in the deck above the cone, several hands being stationed in the

tank to guard against kinks forming, or the cable fouling. In loading the vessel the cable from the top of one tank is led over into the bottom of the adjacent tank, making it necessary only to slacken the speed of paying out when changing over from one tank to the next.

From the tank the cable passes to the paying out gear. This machinery for controlling the stress on the cable is placed both at the bow and stern All long pay-outs are made over the stern, but it is often more convenient to pay out short sections over the bow, as it is to this point that the cable is brought for splicing. The machine consists of a large drum 6 ft in diameter, around which several turns of cable are taken to provide the necessary friction On the same shaft is a series of water-cooled adjustable band brakes and connected to it is a large fan brake The cable then passes through a dynamometer, which gives an indication of the stress, leaving the ship over the bow or stern guide, as the case may be It is not uncommon for the stress on the cable in paying out in deep water to amount to as much as two tons In order to check the amount of slack in the cable there is paid out at the same time a taut steel piano wire which is carefully measured and compared with the length of cable paid out. When passing over fairly smooth bottom the amount of slack paid out rarely exceeds 10%, but care is taken not to leave the cable in a state of tension on an uneven bottom, or suspended in bights over rocks, etc., as injury to the cable would result.

The heavy shore end of the cable is landed from a smaller ship which is moored close to the beach and a line sent ashore, supported by barrel floats When enough of the cable has been landed the barrels are cut away The remaining length on the smaller ship is then paid out and the end buoyed in water sufficiently deep to permit the deep sea ship to approach The latter takes the buoyed end aboard over the bow, a splice is made, and the cable transferred to the stern The ship then starts on her long voyage When approaching her destination the cable is cut and the end buoyed in deep water. When this shore end of the cable has been laid out to meet the buoyed deep-sea end, both ends are taken aboard and tested; the final splice is then made and the cable dropped over the bow During cable laying testing is carried on continuously by a staff of electricians, whose duty it is to detect and report any fault in the cable

Should the cable develop a fault or break while being laid, the ship is equipped with special means of coping with the trouble. From the results of electrical testing it is possible to arrive at the length of cable between the ship and the fault.

Cable Repairing.—When trouble develops in a submarine cable it is usually possible to localize the fault or break with a fair degree of accuracy by determining the electrical resistance or capacity of the core between the testing point and the point of failure by the Wheatstone bridge method Knowing the characteristics of the cable it is possible to deduce the distance in miles, which interpreted in conjunction with the charted route enables the navigator of the repair ship to place a mark buoy within working range In deep water it is necessary to use a cutting grapnel which automatically grips the cable and cuts away one end when it is lifted The very ingenious construction of the Lucas grapnel permits it to be set so as to cut away whichever end is desired A suddenly increased stress on the grapnel rope which passes through the dynamometer gives an indication when the prongs of the grapnel encounter an obstacle. The vessel is stopped and the picking-up gear is started When the cable has been raised to the surface it is secured with a rope, or chain stopper and taken aboard Test leads are attached to determine the electrical condition of the cable and the fault is localized. When the line is electrically clear to one of the shore stations the end is buoyed. Should the cable be in danger of parting, a length of new cable from the ship's tanks is spliced on and paid out until all the cable suspended off the bottom is new. The ship is then free to go after the cable on the other side of the fault. When this end has been raised and the tests indicate its continuity and satisfactory insulation all the way to the shore station, cable from the ship's tanks is spliced on and paying out commences towards the buoyed end, which, when it is reached, is taken aboard. Final tests are taken in both directions; the cable from the ship's tanks is stoppered off and cut, and the final splice is made on the ship's deck in a bight both sides of which are secured with stoppers, by means of which it is eased over the bow and the lines holding it are cut away.

OPERATION

Simplex.—The simplex method—sending single messages in one direction only—of operating submarine cables is not generally

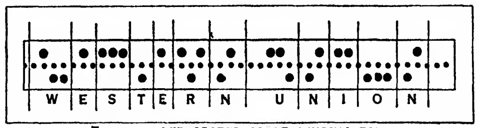

FIG 24.—PERFORATED CABLE SENDING TAPE

employed except where it is difficult to maintain a duplex balance. The cable capacity when using the simplex method is approximately 40% lower than when operated by the duplex method. When it is considered that a modern cable of about 2,000 m in length costs about $4,000,000 and that the annual expense for maintenance and operation is approximately $600,000 it can be readily seen that the highest possible traffic-carrying capacity is essential in reducing operating costs

Duplex.—Duplex operation, or the transmission of messages in both directions at the same time, is made possible by so arranging the recording instruments that while responding to signals from the distant end of the cable they do not respond to signals sent into the end of the cable at which they are located There are several methods of duplexing, all of which depend upon the use of an artificial line for balancing, as is the case in land line duplex operation The artificial line for ocean cable operation must more nearly duplicate the real cable in electrical characteristics and it is therefore designed and built to suit the cable which it is to balance.

Transmission.—Transmission of messages over ocean cables may be accomplished manually or by automatic means. The common code employed is an adaptation of International Morse in which dots and dashes are transmitted as impulses of equal duration but opposite in polarity. The manual means of transmitting the international code makes use of a double lever key, which is so arranged that the depression of one key connects one polarity of battery to the line to form a dot, and a depression of the other key connects the other polarity of the battery to make the dash. In automatic transmission signals are transmitted by means of a motor-driven transmitter controlled by a perforated paper tape The tape is prepared in a keyboard perforator (Plate I, fig 7) by means of which the depression of a single key will perforate the entire combination of dots and dashes corresponding to the letter This tape (fig 24) is then passed through the transmitter in which transmitting contacts for either dot or dash polarity are controlled through mechanical levers by the perforations in the tape. The transmitter is operated at the highest speed permitted by the electrical characteristics of the cable.

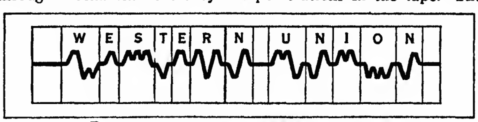

FIG 25.—UNDULATING LINE EMBODYING CODE

Receiving.—The reception of submarine cable signals necessitates the use of extremely sensitive and delicate instruments. The underlying principle of older types of cable receiving apparatus is that of the galvanometer, an instrument whose function it is to determine whether an electric current is present in a given conductor and in what direction it is flowing. The recorder commonly used consists of a galvanometer, to the moving coil of which is attached an ink syphon resting upon a moving paper tape. When no signals are being received the syphon will draw a continuous straight line along the centre of the tape. As signals are received the resulting deflections of the galvanometer will cause

the syphon to move above or below its normal position, causing undulations in the line. Undulations above the centre indicate dots and those below the line indicate dashes.

For operating cables up to approximately 600 m. in length at a speed of about 200 letters per minute the received signal is of sufficient strength to operate the recorder directly from the cable. In order to increase the operating speed of a long cable above a point where satisfactory results can be obtained with a syphon recorder alone, it is necessary to magnify the weakened incoming signals before passing them through the recorder. The instrument most extensively used for this purpose is known as a magnifier, the application of which is similar to that of a Morse relay in land line operation. The magnifier, like the recorder, comprises a galvanometer which is so arranged that deflections of the galvanometer control current in a local circuit containing a recorder. The important feature of the magnifier is maximum sensitivity and to obtain this functional losses and inèrtia of moving parts are kept at a minimum. Several means are employed for accomplishing this purpose. In one type the armature of the galvanometer carries a small mirror which deflects a beam of light so that it will fall on a light-sensitive cell connected in the local circuit containing the recorder. Variations of light intensity falling on the cell cause its resistance to be varied, resulting in corresponding variations in the local current through the recorder. In another common type the galvanometer moves a fine light wire carrying a portion of the local currents into proximity with a heating coil or blast of air, so that it becomes heated or cooled, thus varying its resistance and causing variations in the local current. In recent installations magnifiers have been replaced by vacuum tube amplifiers associated with shaping networks to amplify and improve the shape of the received signals.

Automatic Relays.—In many cases it is desirable to repeat signals automatically from one section of cable into another rather than to record them. It is essential that a cable relay used for this purpose shall have a reliable method for making electrical contact. All of the standard types of cable relays employ the principle of the moving coil galvanometer, and differ only in the method of making contact. A relay may be used with or without a magnifier in the circuit, the relay alone being approximately as sensitive as a syphon recorder. The relay in passing signals merely strengthens the current for the next cable section.

If the signals to be repeated are being received from a cable section approximately 100 m. or more in length, they will be so distorted that the use of a relay of the type described above would be impracticable. In such instances a regenerative type of repeater is used, similar to the regenerative repeaters employed on land lines.

Chief Submarine Cables of the World

In recent years printing systems have been applied to ocean cables, and on the high-speed loaded cables an adaptation of the American multiplex system is being used.

Chief Submarine Cables of the World.—There are at the present time upwards of 3,000 submarine cables in the world with an aggregate length of more than 300,000 nautical miles. The preceding table shows the number and length of important cables operated by Governments and the principal cable companies or systems. Short channel and harbour cables are omitted. Almost 75% of the total cable mileage is privately owned and operated.

TELEKI, PAUL, Count (1879–), Hungarian politician and geographer, studied jurisprudence and geography in Budapest. After being elected to Parliament in 1905 he spent some years in geographical study abroad, and published *Atlas zur Geschichte der Kartographie der Japanischen Inseln* (Budapest, 1909), crowned with the Prix Jomard by the French *Société de Géographie*. He was foreign minister in the cabinet of Admiral Horthy (April 1920), and in July of the same year became prime minister. He resigned in 1921 after the first attempt of King Charles to regain his throne. Later in the year he was appointed professor of economic geography in the University of Budapest. In 1924 he served in a scientific capacity on the commission appointed by the League of Nations to enquire into the Mosul frontier dispute between Great Britain and Turkey.

TEL EL AMARNA, the name now given to a collection of ruins and rock tombs in Upper Egypt near the east bank of the Nile, 58 m. by river below Assiut and 190 m. above Cairo. The ruins are those of Akhet-Atoh, a city built *c.* 1360 B.C. by Ikhnaton (Amenophis IV.) as the new capital of his empire (in place of Thebes) when he abandoned the worship of Ammon and devoted himself to that of Aton, *i.e.*, the sun. Shortly after the death of Ikhnaton the court returned to Thebes, and the city, after an existence of perhaps only twenty years—of fifty years at the utmost—was abandoned. Not having been inhabited since, the lines of the streets and the ground-plans of many buildings can still be traced. The chief ruins are those of the royal palace and of the House of the Rolls; there are scanty remains of the great temple. In the palace are four pavements of painted stucco work in fair preservation. They were discovered in 1891–92 by Prof. Flinders Petrie. In the Rolls House were discovered in 1887 by the fellahin some 300 clay tablets inscribed with cuneiform characters. They are letters and state documents addressed

to Amenophis IV. and his father, from the kings of Babylon, Assyria, etc , and from the Egyptian governors in Syria and neighbouring districts. The greater part of them were purchased for the Berlin Museum, but a large number were secured for the British Museum Their contents proved invaluable for the reconstruction of the history, social and political, of Egypt and Western Asia during that period.

Hewn out of the sides of the hills on the east are two groups of tombs; one group lies 1½ m. N.E., and the other 3 m. S of the city. The tombs, all of which belong to the time of Ikhnaton, are full of interesting scenes in the peculiar style of the period, accompanied by hymns to the sun god. The most important tomb is, perhaps, that of Meri-Ra, high priest of the sun, which has a façade nearly 100 ft. long and two large chambers. In the early centuries of Moslem rule in Egypt the northern tombs were inhabited by Copts, one tomb, that of Pa-Nehesi, being turned into a church.

The tombs and the great stelae sculptured on the cliffs which mark the bounds of the city of Akhet-Aton have been the object of special study by N de G. Davies on behalf of the Archaeological Survey of Egypt. The results, with numerous plates and plans, are embodied in a series of memoirs, *Rock Tombs of El Amarna* (six parts, 1903–08).

TELEMACHUS, in Greek legend, son of Odysseus and Penelope (*Odyssey*, i–iv., xv.–xxiv.; Hyginus, *Fab.* 127). When he reached manhood he visited Pylos and Sparta to make inquiries about his father. On his return, he found that Odysseus had reached home before him. Then father and son, aided by Eumaeus and Philoetius, slew the suitors of Penelope (*see* Odysseus) According to later tradition he married Circe (or Calypso) after Odysseus' death.

TELEMARK or **THELEMARK,** a district of southern Norway, in the *amt* (county) of Bratsberg. It covers the uplands and fjelds of the southward projection of the country, having its highest point in the Gaustafjeld (6,200 ft.); and contains several large lakes, as Nordsjó, Bandaksvand, Tinsjö, Mjósvand and Totakvand. The two first are connected by the Bandaks canal, giving access from the port of Skien to Dalen at the head of Bandaksvand. From Dalen, a driving road much frequented by travellers runs north-west, through beautiful scenery. It crosses the fjelds at a height of 3,085 ft on the way to Röldal from which branches run to Odde and through Bratlandsral respectively. One of the finest waterfalls in Europe, Rjukanfos (415 ft), provides power for nitric acid works, and Ulefos, near the Bandak canal, for pulp mills. Notodden is a growing town with saltpetre works. Skien, the capital (*q.v.*) is a port; also Kraguö, Porsgrund (pop. 8,850), and Brevik.

TELEOLOGY, in philosophy and biology, means explanation by reference to the realisation of some purpose or end (Greek τέλος, an end), contrasted with explanation by efficient causes only. Teleology is one of the oldest, probably the oldest, mode of explanation. Human conduct is nearly always explained by reference to the ends pursued, or alleged to be pursued; and the tendency to explain everything else after the analogy of human behaviour is very old, as old probably as human nature itself. The method of explanation by reference to ends received formal and explicit recognition in Aristotle's list of four causes which included "final" causes. Aristotle, of course, insisted on the importance of discovering the "material," "formal," and "efficient" causes as well as the "final" causes. But during the middle ages the others tended to be ignored more or less, and too much attention was paid to "final" causes even in physical and chemical investigations, which consequently became rather fantastic. The founders of modern science had a hard struggle to instate or reinstate the "mechanical philosophy" at least side by side with teleological explanation The pendulum naturally swung to the other extreme. Not only physical and chemical phenomena, but even biological phenomena were explained mechanically. Descartes, for example, regarded the lower animals as mere automata. In time, however, it was found impossible to explain biological facts adequately by means of mechanical conceptions only, and teleology of one kind or another has met with increasing recognition in recent times.

See Mechanism; Emergence; Evolution; Metaphysics; Scientific Method; L T Hobhouse, *Development and Purpose* (1913, etc.).

TELEOSTEI. In the classification issued in 1846 by Johannes Müller, the recent bony fishes were arranged in three sub-classes, Dipneusti, Ganoidei and Teleostei, the last including the great majority of the fishes, all those with a homocercal caudal fin Subsequent work, especially on fossil fishes, has shown that the ganoids are not a natural group, some being related to very primitive fishes, others approaching the teleosts, namely the Holostei, which include the recent *Amia* and *Lepidosteus*. The extinct Pholidophoridae and Oligopleuridae are exactly intermediate in structure between the Holostei and Teleostei, and have been included by some authorities in the one group, by others in the other. This has led C T Regan to combine the Holostei and Teleostei to form one sub-class, termed Neopterygii. (*See* Fishes.)

TELEOSTOMI, a name given by some authorities to the bony fishes, either with or (usually) without the lung-fishes; in the former sense it is equivalent to the class Pisces, above the level of the Selachians. (*See* Fishes)

TELEPATHY was defined by F. W. H. Myers, who invented the word in 1882, as "the communication of impressions of any kind from one mind to another, independent of the recognized channels of sense." It is to be noted that Myers does not postulate that both or either of the minds he mentions should be the minds of living persons; for supernormal communication between the minds of living persons the phrase "telepathy between the living" should in strictness be used, but often "telepathy" by itself is loosely used in this sense. "Thought-transference" is a less technical word with the same meaning. (*See* also Clairvoyance, Psychical Research)

TELEPHONE. In a broad sense, the term telephone or telephony includes the entire art of speech transmission with the many accessories and operating methods which research, development, and invention have supplied to facilitate and extend conversation at a distance by electrical means. The telephone was invented in 1876, at Boston, Mass , U S A., by Alexander Graham Bell (*q v*) While endeavouring to construct a "harmonic telegraph" with which he hoped to send several telegraphic messages simultaneously over a single wire, Prof. Bell was also trying to transmit speech electrically. On June 2, 1875, he succeeded in transmitting by wire the sound of a twanging clock spring Further experiments produced on March 10, 1876, an instrument which successfully transmitted a complete sentence, Prof Bell's summons to his assistant in another room: "Mr. Watson, come here, I want you " Bell himself, during his experiments, stated the correct principle of telephone transmission as follows:

> If I could make a current of electricity vary in intensity precisely as the air varies in density during the production of sound, I should be able to transmit speech telegraphically.

Bell was the first to utilize a continuous current, intensified and diminished in proportion to the sound waves projected into the transmitter. Others had predicted the possibility of transmitting speech by wire but had not hit upon the only practicable method. Charles Bourseul, a Frenchman, published an article as early as 1854 in which he described a method that he believed might be used to transmit speech electrically. An Italian named Antonio Meucci, about 1857 sought some way of transmitting the voice by wire. In 1861 Philipp Reis, a German, produced an instrument constructed along lines similar to those laid down by Bourseul, which would transmit sound of a constant pitch, but proved incapable of transmitting continuous speech. In the United States, several other experimenters were working along lines similar to Bell's at about the same time. Prof. Elisha Gray, in fact filed a caveat (*q v.*) on the subject in the United States Patent Office only a few hours after Bell filed his application for a patent on his "improvement in telegraphy," as he described his invention of the telephone The claims of Prof. Gray and of other American inventors, notably Prof. A. E. Dolbear and Daniel Drawbaugh, were threshed out in prolonged litigation which resulted in Bell's patent being upheld and his claims to be the inventor of the telephone being officially established.

Introduction.—Public apathy in the United States and in Great Britain and other countries was one of the most disheartening difficulties faced by those who were endeavouring to introduce the telephone. The development of the telephone business was undertaken by a group of Prof. Bell's backers, under the leadership of Thomas Sanders and Gardiner G. Hubbard, whose daughter Bell soon afterwards married. They began renting or lending telephones in pairs to individuals for local communication. The telephoning was all done over a single iron wire connecting the two instruments with grounded return circuits. There were no switchboards to afford communication among a number of users, calling devices were extremely crude and transmission was uncertain and poor at best.

In 1878 the first telephone switchboard for commercial service was placed in operation at New Haven, Conn., with twenty-one subscribers. Those interested in introducing the Bell telephone to public use early adopted the permanent policy of leasing telephones instead of selling them, and granted licenses to authorized agents or licensees for the commercial development of the telephone business in many parts of the United States. These licensee agencies gradually developed into local exchange systems and ultimately into local operating companies. The owners of the telephone patent early incorporated their business, and funds were raised for its progressive development, under the leadership of Theodore N. Vail, who became General Manager in 1878. Within ten years after the issuance of the Bell patent the Bell Telephone System had attained an organization approximating its present form. The local systems were gradually brought together into regional companies operating throughout a state or several states. The telephone systems of these regional companies were linked together by long distance circuits operated by the American Telephone and Telegraph Company. This company was originally formed to build and operate the long lines as a subsidiary of the American Bell Telephone Company, which had become the parent company of the Bell System by acquiring the ownership of the Bell patents and purchasing stock in the regional telephone companies. Later the American Telephone and Telegraph Company exchanged its stock for that of the American Bell Telephone Company and became the parent company of the Bell System.

Growth of the Business.—Following the expiration of the basic telephone patent, a large number of so-called "independent" telephone companies, not affiliated with the Bell System, were established all over the country. In many cases these companies brought telephone service to places in which the Bell System did not operate. Some, however, engaged in competition with the Bell telephone companies in their localities; and it required actual experience of the inconveniences of telephone competition to convince the public of the fact that two telephone companies in a single community are a source of annoyance and unnecessary expense to the telephone-using public. The fact that one had to subscribe for both of the competing telephone services in order to be in communication with all of the telephone subscribers in the locality finally resulted in a popular demand for the unification of the telephone service. In many communities competing telephone systems were consolidated. Other independent companies were afforded facilities for physical connection with the lines of the Bell System. The linking up of these local telephone systems, which are now known as "connecting companies," makes possible interconnection among more than 99 per cent. of all the telephones in the United States. Subscribers of the Bell telephone companies and of the connecting companies are thus alike afforded access over the long distance lines of the Bell System to almost any other telephone anywhere in the United States as well as to other countries in North America and overseas.

On March 31, 1929 the twenty-four Associated Companies, which with the American Telephone and Telegraph Company make up the Bell System, owned and operated 14,784,000 telephones and 6,242 central offices. In addition, the connecting companies, which number nearly 8,300 besides more than 30,000 Bell connecting rural lines, owned and operated 4,670,000 telephones and 13,065 central offices. There were also in the United States at that date 142,000 telephones owned and operated by companies not affording physical connection with the Bell System. The total investment in telephone plant and equipment in the United States was, on March 31, 1929, over $3,850,000,000, of which $3,415,-000,000 represented the investment of the Bell System. During the year ending March 31, 1929, the Bell System traffic averaged daily 57,448,000 exchange conversations and 2,902,000 toll conversations, a total of 60,350,000. In addition, the connecting and non-connecting companies transmitted a daily average of 17,900,-000 exchange conversations and 370,000 toll conversations, a total of 18,270,000 conversations. The grand total of telephone messages for the United States during that year was more than 78,000,000 completed conversations a day. About 415,000 persons are employed by the telephone industry in the United States, of whom 350,000 are employees of the Bell Telephone Companies. In addition, some 65,000 are employed by the Western Electric Company, which manufactures standardized telephone equipment and apparatus for the Bell System. The Bell Telephone Laboratories, Inc., which conducts research along lines connected with every phase of the electrical transmission of speech, employs a total of about 5,100 people.

DEVELOPMENT AS TO USE

The telephone industry in the United States has attained its present development in response to a rapid and sustained growth in public demand for telephone service throughout the country. This is illustrated in the following table showing the increase in the total number of telephones in the United States since 1877:

Telephone Development in the United States

End of year	Number of telephones	Telephones per 100 population
1877	2,600	0·005
1880	47,900	0·09
1885	155,800	0.27
1890	227,900	0·36
1895	339,500	0.48
1900	1,355,900	1·76
1905	4,126,900	4.85
1910	7,635,400	8·10
1915	10,523,500	10.39
1920	13,329,400	12·43
1925	16,935,900	14.76
1927	18,523,000	15·79
1928	19,341,000	16.32

This growth is evidence of the extent to which the American people have acquired the "telephone habit." In rural sections the telephone has mitigated the discomforts of life in isolated farm houses, and is of assistance in marketing.

The usefulness of the telephone is largely increased by the fact that it has become almost universal, so that practically any point can be reached by telephone. Business concerns find it profitable to make the telephone service an integral part of the organization for the administration of their business, thus keeping their main offices in direct, constant touch with branch establishments and travelling representatives, and making systematic use of the telephone in sales campaigns. The uses of the telephone for business, social and other purposes are, of course, too numerous to be mentioned in detail. In newspaper work, in connection with police and fire protection, in train dispatching, in the operation of taxicabs, in finance, in personal shopping, the telephone is filling an ever wider field of usefulness. It is said that New York brokerage houses do more than 75 per cent. of their business by telephone.

TELEPHONE PLANT IN THE UNITED STATES

The term "telephone plant" includes (1) the telephone apparatus and wiring at the subscribers' premises; (2) the central office switching equipment (with the buildings that contain it) for interconnecting subscribers' lines; and (3) the aerial and underground wires and cables with their pole lines and conduits, which connect the subscribers' stations with the central offices and the latter with each other, whether they be in the same city or in different cities. This plant makes it possible, at the present time, for any user of the telephone service to be connected promptly with any other station of the telephone system, and to converse easily,

by electrical means, with the person called, after the connection is established, regardless of distance. The systems which enable this nation-wide service to be rendered are necessarily complex and intricate and they include a multitude of auxiliary devices and appurtenances. The following brief description deals only with the principal kinds of telephone plant.

Plant at Subscribers' Stations.—This includes the sets (of either the "wall" or "desk" pattern); receivers, transmitters, and induction coils; bell boxes, coin boxes, paystation booths and also the private branch exchange switchboards, such as are found in hotels, department stores and large mercantile establishments.

Substation Sets.—There are three types of telephone sets in general use: (1) the "wall set" (Plate I., fig. 4) adapted for attachment, at convenient height, on the wall of a room; (2) the "desk set" consisting of a pedestal, rising from a substantial base, and supporting the transmitter, and the receiver hung on a switchhook; (3) the "hand set" (Plate I., fig. 5) in which a transmitter and a receiver, of suitable design, are attached at opposite ends of a handle. This unit normally rests on a cradle surmounting a circular base. Both "desk" and "hand" sets are provided with flexible connecting cords so that they are movable within the limits fixed by the length of the cord. With them is used a bell box, usually mounted beneath a desk or in some other inconspicuous place, containing the call bell, induction coil and other auxiliary apparatus. For carrying on the telephonic conversation, two instruments are required, the transmitter and the receiver. The former converts the speech waves in the air into their electrical replicas on the wire; the latter performs the reverse operation of converting electrical speech waves into sound waves in the air.

At first, a single instrument, placed alternately to the mouth and the ear, was used for talking and listening. Shortly, however, it was found desirable to provide each subscriber with two identical instruments, one (the receiver) to be used for listening, the other (the transmitter) to be used for talking Bell's first instruments required a battery in the circuit, but the instruments that were first employed commercially had permanent magnets and the speech currents were generated by the motion of the diaphragm.

The Receiver—Although the basic scientific principle of the modern telephone receiver follows the original invention of Bell, the structure and design of the instrument have been changed in every essential feature and its efficiency has been greatly increased as the result of continuous experimentation and development work. An early commercial type of receiver was known, from its shape, as the "butter stamp." To the end of a permanent magnet was attached a soft iron pole-piece on which was wound a coil of insulated, fine wire. A circular diaphragm of iron, supported by the case or shell of the instrument, was placed with its center close to the end of the pole-piece, but not in contact with it. Speech currents, passing through the winding, varied the attraction of the permanent magnet for the diaphragm, causing the latter to vibrate and produce sound waves in the air corresponding to the speech currents.

Plate I., fig. 2, shows a cross-section of a type of receiver now widely used in the United States Among the improvements embodied in it are a bipolar magnet with two pole-pieces and windings, welded construction, dust-proof case, special kinds of steel, accurate spacing of diaphragm and pole-pieces and, throughout, the most effective proportioning of its parts. These features collectively have resulted in increasing its efficiency and the naturalness of its reproduction of the voice.

The Transmitter.—The transmitters first used were of the magneto type, similar to receivers, but Bell himself early pointed the way to improvements by his liquid transmitter which contained the principle of the variation of the electrical resistance of the transmitting element under the control of the vibrations of the voice. Important improvements in the transmitter came from the use of the principle of the microphone, employing variable resistance contacts in a battery circuit. Following the Berliner and Edison transmitters of 1877 based on this principle came the Blake transmitter, an improved type, introduced into the Bell System in 1878. These early instruments were superseded by the granular carbon type, growing out of an invention by Hunnings and employing a variable resistance element consisting of a small chamber filled with granules of carbon. The "solid back" type, an improved form of granular carbon transmitter and a prototype of modern instruments, was the invention of Anthony C. White. Scientific research has been continuously, and still is, directed toward the further improvement of transmitters. Plate I., fig. 1, shows a cross-section of a modern telephone transmitter.

Substation Wiring Plans.—In the case of business offices and residences, additional telephone facilities in great variety, beyond the scope of a single set, are frequently employed to meet the ever-increasing requirements of modern life. "Extension" telephone sets, connected with the substation line, enable calls to be originated or received from different points in the subscriber's residence or place of business. By pressing a button, an extension telephone may be cut off when desired and, where several stations, and more than one line are provided, any one of the stations may be connected to any one of the lines. In some cases, means are provided whereby a secretary may answer calls on either of two lines and, by suitable switch keys, perform various operations such as holding a call on one line while the principal is talking on another. Many combinations of master stations, control stations and extension bells in combination with one or more lines are available for the telephone user.

Private Branch Exchanges.—A "private branch exchange" is a switchboard, generally of small size, located at the subscriber's premises. To it are connected the substation sets of the subscriber's establishment and it is connected with the central office switchboard by a sufficient number of trunk lines to handle the traffic. Plate I, fig 3, shows a private branch exchange switchboard for a small number of stations and trunk lines. This is capable of being placed on a desk and operated by a clerk who may also perform other duties. With this equipment all of the operations of connecting and disconnecting the local stations with each other and with the central office are performed by means of switch keys Larger private branch exchanges resemble small central office switchboards, and require the attendance of one or more operators Private branch exchanges are also available which operate in a manner similar to the dial central offices to be described later.

Central Office Switching Equipment.—To enable telephone conversations to take place, two substations must be connected together by a pair of wires constituting an electrical circuit called the "line." If each person having a telephone wished only to talk to one other person and never to any others, the telephone plant would be very simple. Its complications arise from the necessity for connecting together and providing a satisfactory talk between any two of more than 19 million stations in the United States. This is a very important aspect in which telephone service differs from such services as water supply, gas and electric light and power, where each customer satisfies his demands by drawing what he needs from a set of mains, and the demands of other users do not normally affect his own service

To the central office switchboard runs one line (ordinarily one pair of wires) from each telephone individually served. The switchboard must provide means, such as tiny electric lamps, one associated with each line, whereby the calling party can signal the operator when he removes his receiver from its switchhook to originate a call; means such as a cord and plug and listening key whereby an operator can connect her telephone set momentarily to the calling party's line to receive the call; means such as the multiple and out-going trunk jacks to enable the operator to connect the calling party's line with the line of the person with whom he wishes to talk, whether that line be connected to the same switchboard as is his own, or to some other switchboard in the same city, or whether it must be reached over a trunk line to some suburban point or over a "toll" or "Long Distance" line extending to some remote city or town; means for determining whether the line called for is already in use, or "busy"; means for ringing the bell at the called station and, finally, when signals indicate that the conversation is ended, means for restoring all circuits to a state of readiness for another call. Switchboards may be either manually operated or of the "dial" type. The general

FIG. 1.—SCHEMATIC DIAGRAM OF TELEPHONE CONNECTION IN COMMON BATTERY EXCHANGE

When the subscriber (left) removes his "Receiver" from the "Switchhook" an electrical circuit is completed through his set, the "Line Relay" and the battery at the Central Office (the several batteries shown are actually one common storage battery). The armature of this relay closes the circuit through the "Line Lamp" associated with his line, causing it to glow and attract the operator. She inserts the "Answering Plug" in the subscriber's "Answering Jack" and by operating the "Talking Key" is enabled to talk with him. Ascertaining the number desired, she touches the tip of the "Calling Plug" to the sleeve of one of the "Multiple Jacks" associated with the line having that number. If the line is "not busy" she inserts the calling plug and uses the "Ringing Key" to call the subscriber. The heavy lines show the paths of the voice currents in the completed connection. The "Cut-off Relay" disconnects the line relay from across the line when a plug is inserted in either the multiple or answering jacks. "Supervisory Lamps" are controlled through the "Supervisory Relays" by the position of the subscriber's receiver or handset. In the circuit shown both lamps are dark showing that the subscribers have their receivers off and are talking. When both supervisory lamps light she knows the conversation is finished and will take down the connection by removing the plugs from the jacks

functions of the dial system are similar to those of the manually operated system, the electro-mechanisms of the former, however, being so contrived that most operations, instead of being performed by human operators, are completed by means of switches set in operation and controlled by the electrical impulses which are sent over the line from the substation dial.

There are certain limits to the number of telephones which can be given service advantageously on one switchboard. One of these is the economic limit which indicates that, in order to keep down the length and cost of the lines connecting the telephones with the central office, the subscribers' stations in certain conveniently sized areas should be grouped to one central office in each area and the several central offices interconnected by trunk lines. The locations for the central offices, the boundaries of their areas, the type of switchboard to employ and the character and number of the trunk lines are all matters requiring careful study and intricate planning. To reach the smaller central offices, in outlying sections of a large city, from central offices in a distant portion of the city, it is sometimes desirable to use two or more trunk lines connected in "tandem" by the various operators at the points between the two offices.

Historical.—The first telephone switchboard was put into service in New Haven, Connecticut, on January 28, 1878, and provided primitive means for accomplishing the fundamental operations of interconnecting substation lines. It served 21 stations on eight grounded lines. In contrast, Plate I., fig. 6 shows a large manually operated switchboard in use in 1928. Such switchboards as this are capable of serving perhaps 20,000 telephones on 10,000 lines and may require as many as 120 operators on duty at the busiest period of the day. One of these large switchboards takes over a year to build and install. It will frequently contain as much as 4,000 miles of internal wiring and as many as two million soldered connections. Plate II., fig. 3 is a rear view of a section of this kind of switchboard and Plate II., fig. 5 shows the "main" frame by means of which the subscribers' lines are connected with the switchboard.

The electrical circuit of the manually operated common battery switchboard is shown diagrammatically in fig. 1, its operation being explained in the text below the figure. Switchboards employing electrical mechanism, controlled by dials at the subscribers' stations, to replace human operators as far as practicable, have come into wide use both in the United States and elsewhere. This "dial" apparatus is the subject of a subsequent section. The "multiple" principle was an important step in the evolution of the modern type of switchboard. It is employed in dial as well as in manually operated switchboards. As the telephone business grew, the number of subscribers which a single operator could serve was soon exceeded. For a time the situation was met by providing trunk circuits from one operator to another, but this reduced the speed of service. The invention of the multiple principle relieved this condition by permitting any one of the operators at a switchboard to establish a connection directly between any subscriber whose line she served and any other subscriber connected with the switchboard.

In the multiple system, a "jack" or switch for every line is placed within the reach of each operator at the switchboard. In practice this means one multiple jack per line for every three adjacent operators. With the provision of this increased facility for interconnecting subscribers' lines, it became necessary for the operator to know whether or not a line, with which connection was desired, was already in use through a connection made at some remote part of the switchboard. The method and means for determining the condition of the line is known as the "busy test." Its invention was a necessary accompaniment to the use of the multiple principle. To accomplish the busy test the operator touches the "sleeve" of the jack with the "tip" of a connecting plug. If the line is busy, a click is heard in the operator's receiver. Plate II., fig. 3, shows the rear of a multiple switchboard; the upper part of the cabling is that used to carry the "multiple" of subscribers' lines through the switchboard.

For many years batteries were required at each subscriber's station to furnish the current for actuating the transmitter. An important forward step was the development of the common, or centralized battery, system of operation in which a storage battery at the central office overcame the necessity for local batteries at the individual substations. The common battery system also provided a way by which the subscriber could signal the operator merely by removing the receiver from its switchhook, thereby lighting a tiny electric lamp associated with his line at the switchboard. Before this system was devised and perfected, the subscriber signaled the central office by turning a crank that caused a small electrical generator to send a current over his line which operated an electro-mechanical annunciator or "drop" at the switchboard. Improved forms of the latter system, known as the "magneto," are still advantageous for use in small communities.

Buildings.—While, in small communities, telephone central office equipment is frequently installed in rented quarters, in the larger places the requirements of the service usually make desirable the erection of buildings specially adapted for telephone purposes. The headquarters buildings, located in the larger cities, generally house not only the central administrative forces of the

telephone company, but often several central office switchboards.

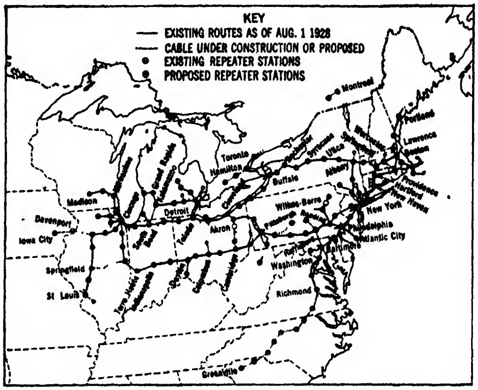
Telephone Lines.—Telephone lines connect (1) each telephone to a central office; (2) each central office in a city to every other central office in that city; and (3) all cities, towns, villages and community centres, by means of a vast network of wires. These wire lines are of two forms—cable and open-wire. Cable consists of insulated copper wires, twisted in pairs and assembled into a core which is covered with an envelope of lead alloy. Ninety per cent. of the telephone wire mileage in the United States is in cable placed either in ducts beneath the streets or suspended aerially by means of steel rope attached to poles. Open-wire lines consist of bare wires, generally of copper, attached to glass insulators supported on pins in crossarms attached to the tops of poles. The lines in a city area may be divided into two classes: (1) Subscribers' lines connecting the subscribers' stations to a central office and (2) trunk lines which connect the offices together. In a typical city installation, a rubber covered pair of wires, known as the "drop" wire, runs from the subscriber's premises to a cable terminal In densely built blocks the connection is frequently made by wires attached to the walls of buildings From the cable terminal, the line is continued toward the central office in a small cable, often containing 25 or 50 pairs of wires and known as "block" cable, which connects with the larger "feeder" cables that run as directly as practicable to a central office. In densely built areas the feeder cables are generally placed in underground ducts; elsewhere they are placed overhead.

As the result of the cable development work described in a later section, telephone cables containing many hundreds of pairs of wires are now available and are employed in the more congested districts. Plate I, fig. 8 shows a cable, of the type used for main feeder routes, containing 1,818 pairs of 26-gauge wires The installation of the subscribers' cable distribution plant, consisting of block cables, and main and subsidiary feeder cables is preceded by a careful engineering study of the present and probable future demand for telephone service in order that the plant may be so planned as to enable these demands to be adequately met.

Trunk cables usually contain larger wires than subscribers' cables. In large metropolitan districts, where there are many central offices, the number of trunk circuits required is very large; sometimes as high as one trunk circuit for each eight subscribers' lines. Trunk routes are usually "double-tracked," *i.e*, two groups of circuits (one for traffic in each direction) are ordinarily required between each pair of central offices, except where tandem or intermediate switching is employed. To provide adequate transmission efficiency in the case of the longer trunk circuits, it is frequently economical to "load" them, as described in a subsequent section. The loading coils are contained within large iron cases. The cable pairs used for subscribers' line distribution and inter-office trunking form the great bulk of the 70 million miles of wire used for telephone purposes in the United States.

Toll and Long Distance Lines.—Until comparatively recently, the toll and long distance plant was composed largely of open-wire lines, the largest size of hard drawn copper wire employed being 165 mils in diameter, weighing 435 pounds to the mile. Within recent years, radical improvements in the telephonic art have permitted the use of long intercity cables in increasing amounts until, at the present time, fully two-thirds of the toll and long distance wire mileage is in cables which cover important backbone routes. Fig. 2 shows present and proposed routes in north-eastern United States One of the first of these long intercity cables was placed in service in 1906, between New York City and Philadelphia. In 1913 an underground cable was provided between Boston and Washington to care for the rapidly increasing traffic and to insure service under such weather conditions as might affect open-wire lines adversely. This cable was equipped with loading coils. It provided a storm-proof route along the northern Atlantic coast. Many of the more recent long cables shown in fig. 2 have been of the aerial type except where passing through urban areas. They have combined the use of loading coils and telephone repeaters and, for the longer distances, so-called "four-wire" circuits have been used in which a separate pair of wires is utilized for transmission in each direction.

The sheath of a typical long cable is about $2\frac{5}{8}$ in. in outside diameter The conductors placed in such a cable are usually either 51 mils in diameter, weighing 41 lb. to the wire mile or 36 mils in diameter, weighing $20\frac{1}{2}$ lb. In the construction of this type of cable, two wires, each insulated with dry paper, are first twisted together to form a "pair." Then two of these pairs are twisted together to form what is termed a "quad." Each quad



BY COURTESY OF THE AMERICAN TELEPHONE AND TELEGRAPH CO

FIG. 2—MAIN TOLL CABLE ROUTES IN THE NORTH-EAST SECTION OF THE UNITED STATES

furnishes three talking paths:—two "physical" circuits and one "phantom" circuit, the latter resulting from a combination of the two physical circuits. Approximately 140 of these quads formed together and enclosed in a metallic sheath make a full-sized cable which, in a typical case, furnishes about 300 telephone circuits and an equal, or even greater, number of telegraph circuits. The cable is attached to a steel wire strand of high tensile strength strung on short stocky poles. Nothing short of a storm of most unusual severity can interrupt service with construction of this type In passing through cities, the cable is usually placed in underground ducts. Loading coils are connected in each telephone circuit a little over a mile apart and, at intervals of about 50 miles, "repeater" stations for amplifying the speech currents are placed along the route

EXAMPLES OF IMPROVEMENTS

Many times during the more than 50 years that have elapsed since the invention of the telephone, scientific research and engineering development have not only found the way out of difficult situations which threatened to hamper the growth of telephone service but, in advance of immediate needs, they have often created new instrumentalities which, in turn, have led to further extensions and improvements of the service.

Cables.—Telephone cables not only provide the sole means for placing a large number of telephone circuits compactly either overhead or underground, but they enable the lines to be carried across the beds of rivers and other waterways. In the cables first employed, single wires with a ground return were used and the wires were insulated with either gutta-percha or rubber. It was soon found, however, that such cables were not well suited for telephone purposes. After experiments with many kinds of insulating materials it was found that dry paper was the best for telephone cables. This discovery and the concurrent development of means for encasing the paper insulated wires in a metallic sheath or tube which protected them from moisture laid the foundation for the modern telephone cable. Research and development covering many materials and processes have made it possible gradually to increase the number of pairs of wires, in a full-sized cable for subscribers' lines, from a maximum of 50 in the year 1888 to 1,800 in 1928 This progress has resulted in a greatly increased effectiveness of utilization of the space in under-

ground ducts in addition to other marked advantages, including a reduction in the cost per mile of cable pair (including ducts) to less than one-tenth of its cost in 1888. The increase in the number of pairs in a single cable has been accompanied by a reduction in the size of the wires, those used in the 1,800-pair cable, for example, weighing only about 4 lb. per wire mile, while those used in the 50-pair cable, of 1888, weighed about 25 lb. per wire mile. Such fine wires could not be used had it not been for improvements in many other parts of the telephone plant, such as transmitters, receivers and coils. Plate II., fig. 2 shows a 1,200-pair subscribers' cable with its wires fanned out. The design, manufacture, laying and splicing of cables, as well as the choice of a type to meet a given set of conditions, have required a large amount of engineering study. A typical problem has been the prevention of "cross-talk," or overhearing, between the pairs necessarily placed close together in a large cable. This has been accomplished by twisting the wires together according to various plans.

Loading.—For some time prior to the year 1900, it had been known to those technically skilled in the art of telephony that the transmission efficiency of long telephone circuits could be improved by increasing their electrical property known as the "uniformly distributed inductance." This knowledge did not, however, lead to practically beneficial results because no one was able to suggest any feasible method of increasing this property of a telephone circuit without bringing in, at the same time, difficulties of one kind or another which were fatal. Numerous investigators sought unsuccessfully to simulate the beneficial effect of increasing the uniformly distributed inductance by introducing, into the circuit, inductance concentrated, or lumped, in the form of coils. It was reserved for Professor Pupin of Columbia University to discover, in 1900, that the proper spacing of the coils along the telephone circuit was the key to the solution and it was from failure to establish this that earlier workers had failed.

The term "loading" comes from the mechanical analogy of a "loaded" string, the study of which was utilized in developing the theory of electrical "loading." When a series of small weights was placed at intervals on a string it was found that mechanical waves, produced in the string, did not die out as quickly as when the string was not weighted. The mechanical loading reduced the dying out of the waves in the string and the analogous electrical loading reduces the attenuation of the waves of speech current in the telephone circuit. It makes the line a better path for electrical waves. To indicate its practical value, it can be stated that, under favourable circumstances, a loaded cable circuit is as good a conductor for telephonic currents as would be a non-loaded circuit of conductors weighing about eight times as much.

Loading, in telephony, is accomplished by inserting coils of wire, wound on toroidal iron cores, into the telephone line at regular intervals. In addition to reducing the attenuation of the electrical waves, loading has another beneficial effect. Telephony requires the transmission of waves having frequencies ranging from about 200 cycles per second to more than 2,000 cycles per second. Plate I., fig. 7, is a photograph of an oscillogram showing the electrical waves produced when the word "telephone" was spoken into a transmitter. Good voice reproduction from the receiver requires that the complex wave shape of speech, including the entire "band" of frequencies, must be transmitted over the line with as little distortion as possible. Loading assists to an important degree in accomplishing this. The principal fields of application for loading are (1) in the case of the longer trunk circuits interconnecting the central offices in the larger cities and (2) in association with telephone repeaters permitting the use of cables, instead of wires spread out on crossarms, for the groups of circuits that link distant cities together.

The latest improvement in loading coils is the result of a basic scientific discovery by G. W. Elmen, in the Bell Telephone Laboratories, of a material called "permalloy" having new and unusual magnetic properties peculiarly suited to the requirements of telephony. The permalloy used in the cores of loading coils is an alloy of about four-fifths nickel and one-fifth iron, specially heat treated. The use of this material has made possible not only a reduction in the size of loading coils to about one-third of their previous size, accompanied, in spite of the more expensive material, by a reduction in cost, but also, due to the reduction in size, smaller cases can be used to contain the coils, resulting in space economies in the underground vaults.

Repeaters.—As the telephonic currents pass over the line, they decrease in strength so that, after travelling a distance which varies with the character of the line, they become too weak to actuate properly the telephone receiver. The idea of inserting one or more repeaters in a line for the purpose of reinforcing the telephonic currents from some local source of energy is almost as old as the telephone itself, but many years elapsed before the quest for a satisfactory repeater culminated in success. The solution of this problem involved the production of a repeater element which, when actuated by weak telephonic currents, is capable of emitting greatly strengthened currents without appreciable loss in the clearness of voice transmission. A so-called "mechanical" element was first used but this presented inherent limitations owing to the mechanical inertia of the moving parts. A satisfactory solution of the problem was found by improving and utilizing the three-electrode vacuum tube in which the weakened speech currents control a local source of energy by means of a practically weightless stream of electrons. The three-electrode vacuum tube of De Forest, prior to its development for use in telephone repeaters, was employed for radio telegraph reception. In the form in which it was used for that purpose it was found to be quite unsuited to meet the rigid requirements of telephony. A large amount of research and development work was required before a satisfactory tube could be produced. The continuing work on the development of tubes has involved the fundamental study of electronic emission from heated filaments together with the study of proper materials and dimensions for the elements of the tube, means for securing a high vacuum and other necessary conditions.

To illustrate the progress that has been made it can be stated that the life of the vacuum tube most commonly used in 1917 was about 1,000 hours. Tubes of a new type first introduced in 1927, have a life of fully 25,000 hours, which is equivalent to about three years of continuous operation. In addition, the first cost was reduced by more than one-half and the power required to heat the tube filaments was also reduced to less than one-half of that required in 1917. The amount of testing needed to secure good operation was likewise decreased. As an indication of the extent to which repeaters are used in the telephone plant in the United States, there were more than 90,000 vacuum tubes in use for this purpose at the end of 1928, and it is estimated that 90,000 more will be placed in service during 1929. The repeater element would have been of little use without the concurrent development of efficient and convenient circuits and auxiliary equipment to enable the repeater element to be associated properly with the line circuits. This problem was partially solved as early as 1904 when an elementary form of mechanical repeater was first used commercially. The development of a satisfactory repeater has carried with it the necessity for extensive investigations of the characteristics of telephone lines in which the repeater must work. Not only must the electrical characteristics of the line be accurately known but the use of repeaters has a bearing on the type of line circuit selected and on the type of loading employed. A long cable with its repeaters, loading, associated switchboard apparatus, echo suppressors and temperature controlled transmission regulators must be engineered as a unit in order to obtain the best overall results.

Dial Telephones.—As progress was made in the improvement of manually operated switchboards, the tendency was constantly toward the substitution of automatic devices for human labour. The accomplishments in this direction became more marked after the introduction of common battery operation with lamp signalling. After a time, so much progress in this direction had been made that the question began to be raised whether ultimately in large cities it might not be possible to eliminate the operator entirely by the substitution of electrically controlled machinery. The development of automatic switching has paralleled that of

other forms of switchboard. Basically, all forms of automatic switching involve the substitution of electrical impulses for the voice of the subscriber in making known his desires and the use of electrical machinery instead of human operators at the central office as the means for interpreting these desires and performing the desired switching operations. Modern panel type automatic switching equipments such as are employed in great metropolitan areas are so complex as to require the concentrated attention of specialists for their comprehension All that can be attempted here, therefore, is merely an outline of some of the major steps. U S. patents covering an automatic switching system were first applied for in 1879, but the system which they described never became a commercial success. In 1889, however, A. B. Strowger, invented a system which was subsequently improved by others and is used successfully at the present time under the name of "step-by-step" system Other automatic systems containing important features contributing greatly to the success of automatic switching appeared both in America and abroad

The Bell System became actively engaged in the development of automatic switching equipment prior to 1900. In its desire to perfect and simplify the operation of switching in every practicable way, it sought to determine fundamentally the type of machinery best suited to the needs of a universal service. As a result of protracted and searching inquiry, a large installation of automatic equipment was made in 1914. In this, the central office equipment was of the so-called "panel" type. The installation was designed not as a final test of a complete automatic system but as a trial on a large scale of the efficacy of the machinery which seemed most likely to give the desired results when applied to a complete automatic system. In this trial, the subscribers called the operators in the usual manner but from the operator onward, the connection was completed entirely by the use of automatic switches. As a result of this and subsequent modifications, the details of the panel system were perfected. The first exchange giving complete automatic operation with panel type switches was installed in 1921.

Since that time, the application of dial telephones has grown rapidly until in 1929, about 19 per cent of the telephones in the United States are operated on a dial basis, through either panel or step-by-step switches. Plate II., fig 1, shows a portion of dial operated central office equipment. Before dial systems could be widely employed they not only had to work properly within themselves, but means had to be devised whereby they could also be made to work successfully in conjunction with existing manually operated systems

The foregoing are but a few of the many improvements brought about by development and research. Among others may be mentioned "carrier" telephony, by means of which more than one telephone conversation can be carried on simultaneously over a single line; transatlantic telephony by means of which service is now possible between America and large portions of Western Europe; and telephotography, which enables pictures to be reproduced at distant points.

Extension of Long Distance Communication.—The first "long distance" conversation took place in 1876 over a line two miles in length between Cambridge and Boston, Mass Conversation by telephone became possible in 1880 between Boston and Providence, R.I., and in 1884 between Boston and New York. The long distance lines reached Chicago in 1892 and in 1911 were extended to Denver, Colo. Salt Lake City was connected with the Eastern Seaboard in 1913 In 1915 the first transcontinental telephone line was opened between New York and San Francisco. As public demand for long distance service grew greater, a second line across the country became necessary and in 1923 a southern transcontinental line was opened to service through New Orleans, La., and El Paso, Tex, to Los Angeles, Calif. A third line across the continent was opened in 1927 by way of Minneapolis, Minn, to Seattle, Wash, and Portland, Oregon The reliability of the long distance telephone service has been substantially enhanced of late years by the placing of many of the important lines in aerial or underground cables which are practically storm-proof. Out of a total of about 63,515,000 miles of Bell System telephone wire on March 31, 1929 (consisting of 54,448,000 miles of exchange wire and 9,067,000 miles of toll wire), 66%, or 41,908,000 miles, was in underground cable; about 27%, or 16,937,000 miles, was in aerial cable; and the remainder, 4,670,000 miles, was in open wire.

A large part of the most highly industrialized section of the United States is now covered by the spreading network of telephone cables shown in fig. 2. One cable extends from New York to St Louis, by way of Chicago, and an additional cable has also been placed in service between New York and Cleveland, Ohio. Telephone messages can now be transmitted through cable from Portland, Me., in the northeast, to Madison, Wis., in the northwest, 1,371 miles; to St. Louis, Mo, in the west, 1,538 miles; and to Petersburg, Va., in the south, 683 miles. The cable between New York and Cleveland when utilized to capacity provides facilities for the transmission of 250 telephone conversations and at least as many telegraphic messages simultaneously. The New York–Chicago–St. Louis telephone cable is 1,204 miles in total length, containing 1,036 miles of aerial sections and 168 miles of underground sections. Its total weight is 50,800,000 lb, and it consists of 14,205 sections, having 7,441,000 separate wire splices The aerial sections are supported on 50,700 poles.

Chicago and New York were connected in 1928 by the following telephone cable routes:

(1) New York–Pittsburgh–New Castle–Cleveland–South Bend–Chicago

(2) New York-Pittsburgh-Wheeling-Indianapolis-Terre Haute-Chicago

(3) New York–Albany–Buffalo–Cleveland–South Bend–Chicago

Canada was brought into communication with the United States many years ago A telephone cable under the Florida Straits between Key West and Havana was opened to service in 1921, making it possible to talk between the North American Continent and Cuba. Six years later connection was made with land lines reaching the principal cities of Mexico. Transatlantic telephone service was opened to the public early in 1927 through co-operation between the American Telephone and Telegraph Company and the British Post Office Eastbound transatlantic messages are transmitted over the land lines of the American Telephone and Telegraph Company to Rocky Point, L I, near New York, where a powerful radio transmitting station puts them "on the air" for the long journey across the Atlantic Ocean. The message is then picked up by the British Post Office radio receiving station at Cupar, Scotland, whence it is transmitted over the land telephone lines of the British Post Office. Messages in the opposite direction are sent over the wires to Rugby, England, whence they travel 2,930 miles by radio to the American receiving station at Houlton, Me. At Houlton they are again placed on the telephone wires for transmission to their destination The scope of this transatlantic service has gradually been extended to afford communication from all points in the United States and from Canada, Cuba and Mexico to all points in England, Scotland and Wales, and to a large part of Western and Central Europe including France, Germany, Spain, Belgium, Holland, Switzerland, Denmark, Norway, Sweden, Hungary, Austria, Czechoslovakia, Danzig, and Ceuta, Spanish Morocco, Africa. Thus three continents, North America, Europe and Africa, are now joined by the transatlantic telephone service.

TELEPHONE IN VARIOUS COUNTRIES

The introduction of the telephone and the development of the business in countries other than the United States will be briefly outlined in the following paragraphs. The post-war expansion of international telephone communications in Europe, the recent development of long distance telephone cable facilities in the various European countries, and statistics reflecting the present status of telephone development throughout the world will be presented in the remaining sections of this article.

Great Britain.—Earnest efforts were made by the early backers of the telephone in America to introduce it to use in Europe. Prof. Bell himself visited England and Scotland on his wedding trip in 1878 in the hope of developing a demand for the telephone in his native country. Queen Victoria congratulated Bell upon the success of his invention and offered to purchase a

pair of telephones, but the inventor made her a present of two instruments especially done in ivory. This assisted in bringing the telephone to public attention and in 1879 the first telephone exchange was opened in London with seven or eight subscribers. Several companies were established for the purpose of introducing the telephone in various parts of the United Kingdom, but in 1880 the British courts held that the telephone system was legally a telegraph system within the meaning of the Acts of Parliament making the telegraph a monopoly of the Postmaster General. The British Post Office thereafter issued licenses on a royalty basis to several private companies, which were ultimately consolidated into a single large company. Licenses for the establishment of municipal telephone systems were also issued to a number of cities and several such systems were established.

In 1896 the Post Office bought the long distance lines throughout the United Kingdom and after that the privately owned telephone company confined its activities to the operation of local exchanges. The Post Office, however, began establishing its own local telephone exchanges in London in 1902 and these were connected with the company's system. Upon the expiration of the company's license on December 31, 1911 the Post Office acquired its entire telephone properties by purchase and now operates all telephones in Great Britain, with the exception of the municipal systems at Hull, and the Channel islands of Guernsey and Jersey. Upon the establishment of the Irish Free State the British Post Office transferred to the Free State Government its telephone system in Southern Ireland. In most of the continental countries, as well as in Great Britain, the telegraph system was already a government monopoly when the telephone was introduced. The government telegraph officials in Continental countries, apparently regarding Bell's invention as a possible competitor of the telegraphs, were therefore reluctant to encourage it. In most cases, moreover, the government officials did not feel justified in undertaking the risks of attempting to develop this new means of communication. The usual procedure, therefore, was to allow the private companies to do the pioneer work of bringing the telephone into use under licenses imposing more or less restrictive conditions. However, as the potential factors of telephone communication gradually were appreciated, most of the governments on the Continent took over the company-operated systems and the telephone service was thereafter administered as a part of the postal and telegraph system. Of later years a tendency to turn again to private enterprise for the provision of more adequate telephone facilities has been manifest in Italy, Spain and elsewhere. Motives of military preparedness unquestionably actuated government officials in taking steps in the early days of the telephone to secure full control of all means of communication.

Experience with the telephone in the World War practically revolutionized military practice in the maintenance of communications. The Signal Corps of the United States Army, for example, constructed during the war 1,990 miles of permanent pole line with 28,000 miles of wire, put up 3,230 miles of wire on French poles and installed approximately 40,000 miles of combat lines. American military telephone exchanges on permanent lines in France numbered 273, and those in the advance section numbered 123, besides small temporary field installations. About 1,600,000 long distance telephone calls were handled by the Signal Corps, in addition to local telephone calls estimated at 47,000,000. Other belligerent countries as well drew heavily upon the equipment and personnel of their home telephone organizations to meet the greatly expanded requirements of their military communication systems during the war. For example, about 13,000 out of the 20,000 men in the engineering department of the British Post Office joined the colours.

Germany.—In Germany the telephone was a government monopoly from the very beginning. Heinrich von Stephan was Postmaster General of Germany and Manager of the Imperial Telegraphs at the time when the telephone was first brought to public notice. He was an active administrator, founder of the Universal Postal Union, and was quick to grasp the possibilities of the new invention. In 1877 he wrote enthusiastically to the Imperial Chancellor, Prince Bismarck, of experiments in the establishment of telephone communication between Berlin and Friedrichsberg. He suggested that the telephone be utilized as an adjunct of the telegraph service in rural post offices where there was not sufficient traffic to require the services of a trained telegraph operator. The first public use of the telephone in Germany was along these lines which, it will be noted, differ from its early utilization in the United States. In America exchange service between persons in the same community was the basis of the early public service, the local areas being gradually linked by long distance lines. In Germany, on the other hand, the toll lines came first as a substitute for the more expensive telegraph facilities. Later, however, the German Government introduced exchange service in Berlin, Hamburg, Cologne, Frankfort, Breslau and elsewhere.

A like policy of government ownership from the first was followed in the German states of Bavaria and Wurttemberg. The German Government proceeded with the development of telephone service more actively than was the case in many other Continental countries and at the present time Germany has more telephones in service than any other nation except America.

France and Switzerland.—In France the telephone was first exhibited at the Paris World's Fair in 1878, where it attracted little interest. In the following year, however, representatives of American telephone manufacturers approached the French telegraph authorities with a view to securing permission for the establishment of telephone service in Paris. The French telegraph officials were unwilling to undertake the development of telephone service themselves, but granted concessions on a royalty basis to several different telephone companies. These concessions were passed about from one concern to another until in 1880 they were all consolidated in a single company called the Société Générale des Téléphones. Public telephone service was opened by this company in Paris early in 1881. The French Government established telephone exchanges at Rheims, Roubaix and Tourcoing in 1883 and in several other commercial centres during the next few years. The private company also established exchanges in some other cities besides Paris, but in 1889 its entire system was taken over by the French Government, which has operated the telephone service throughout France ever since. The French telephone system has been developed to a much greater extent in Paris than in the less densely populated sections of the country.

In Switzerland a concession was granted by the government for the establishment of a privately owned telephone system at Zurich in 1880; and the government itself opened exchanges in Basel and Berne during 1881 and a year later at Geneva, Lausanne and Winterthur. After that the government proceeded rapidly with the establishment of new exchanges and purchased the private system at Zurich upon the expiration of the franchise. Since 1886 the government itself has operated all telephones in Switzerland and the service has been developed to a greater extent than in many other European countries.

Belgium and the Netherlands.—In Belgium concessions were granted to a number of private companies which established telephone systems at various cities, but these properties were bought by the government at the expiration of their respective franchises and since 1896 the telephone has been administered as a government monopoly throughout the country. In the Netherlands a number of concessions were issued, several of the most important ones being ultimately consolidated in a single company which also enjoyed the right to establish inter-urban telephone lines. The competition of these lines with the government telegraphs, however, led the authorities to acquire the interurban telephone lines upon the expiration of their licenses. Municipal telephone systems were established in various Dutch cities succeeding those of the private company. The government acquired the remaining exchanges throughout the country and at present the government and municipal local telephone networks are connected by government owned toll lines.

Austria and Italy.—In Austria concessions were early granted to private companies for the establishment of telephone services at Vienna and a number of other important cities. Long distance lines were constructed by the telegraph authorities, who also

opened their first local exchanges in 1887. Subsequently the concessions were bought in by the government and the telephone business became a government monopoly. Much the same course was followed in Hungary Italy granted a large number of concessions for local telephone companies and telephone competition was inaugurated in a number of the important cities. Ultimately, however, the disadvantages of competition became apparent and consolidation took place, either voluntarily or at the instance of the municipal authorities. In 1883 the concessions were regularized and placed upon a uniform basis surrounded by somewhat onerous conditions. In 1892 the conditions surrounding these concessions were liberalized, but Italy nevertheless failed to keep pace with other great powers in the development of telephone service. After various legislative attempts to encourage the private companies the government in 1907 adopted the policy of buying certain of their systems from time to time. Since the accession of the present régime, however, there has been a return to private ownership in Italy, territorial concessions for the operation of local telephone systems in various sections of the country having been granted to private interests while the government has maintained the operation of the long distance lines.

Scandinavia.—The Scandinavian countries have gone further than any other European community in the development of telephone service. In 1880 the International Bell Telephone Co of New York secured local franchises for the Norwegian cities of Christiania and Drammen In the following year local telephone companies undertook the establishment of exchanges in other cities and a competitive system was even opened for service in Christiania. In 1886 the two systems were consolidated and the Bell exchange in Drammen was later acquired by a local company. The telephone soon came to hold much the same place in Norwegian rural life as it does in the sparsely settled districts of America, and although the government did not encourage the construction of lines which would compete with the government telegraphs, the development of telephone networks throughout the rural districts went on apace. Ten years after the introduction of the telephone into Norway it had extended to almost every village and even the small towns were surrounded by lines reaching far into the open country This remarkable development was secured by local enterprise, independent telephone companies being formed in almost every town or village, and in this respect the Norwegian development was a marked contrast to that obtained in France and Italy. The construction of long distance lines in Norway was finally undertaken by large stock companies and ultimately the state took up the policy of acquiring the more important local telephone systems upon the expiration of their respective franchises. The greater part of the telephone business in Norway, particularly in the larger cities, is now operated by the government.

In Sweden, too, the telephone has attained a higher degree of development than in most European countries. The International Bell Telephone Company opened exchanges in 1881 in Stockholm, Gothenburg and Malmö A couple of years later mutual telephone associations were established in many rural communities throughout Sweden and the Stockholm General Telephone Company was established under the leadership of enterprising Swedish engineers to compete with the Bell Company. The two systems were finally consolidated; but later telephone competition was renewed in Stockholm, the government opening an exchange system to compete with that of the General Telephone Company. In 1918 the government acquired the company's system and a certain amount of duplication which had resulted from the competitive situation in Stockholm has since been eliminated The Swedish capital, however, remains the best developed city, from a telephone standpoint, in the world outside of the United States. In Denmark the telephone was introduced and developed by private enterprise and in the year 1928 more than 90% of the Danish telephones are owned and operated by private concerns. Denmark has the highest development in number of telephones per 100 population of any country in Europe.

Spain.—Spain entered upon a new era of telephone development in 1924 when a concession was granted to the National Telephone Company of Spain, a subsidiary of the International Telephone and Telegraph Corporation of New York, for the development of a nation-wide system to supersede the pre-existing governmental and privately owned telephone services which had attained only a relatively limited development. The new company has entered energetically upon the task of providing Spain with an up-to-date telephone system, the equipment being of Spanish manufacture so far as conditions permit. Within a very short time after the concession was granted, telephone communication was established across the Straits of Gibraltar by submarine cable connecting the Spanish wire system with telephones installed in the zone of Spanish military occupation in Morocco Subsidiaries of the International Telephone and Telegraph Corporation also operate telephone systems in Cuba, Porto Rico, Mexico, Chile, Uruguay, Argentina and Brazil.

Telephone development in the rest of the civilized world may be summarized with the statement that while some sort of telephone service is to be found almost everywhere, the facilities have attained a relatively high development in the English speaking dominions of New Zealand and Australia. Japan has more telephones than any other country in Asia, and although the Japanese system suffered a severe setback in the destruction wrought by the disastrous earthquake of 1923, the opportunity is being taken in rebuilding to introduce thoroughly up-to-date and efficient equipment.

POST-WAR DEVELOPMENT OF TELEPHONE LINES IN EUROPE

Increased interest in telephone communication has been manifest in Europe, also, since the War Particular attention has been directed to the extension and improvement of long distance facilities, especially as regards the circuits linking up the various countries on the Continent. Much of the impressive progress that has been made in international telephone communication on the continent of Europe since the war may be attributed to the activities of the International Consulting Committee on Long Distance Telephone Communication. This committee was formed as a result of an international conference at Paris in 1923, at which delegates from Belgium, France, Great Britain, Italy, Spain and Switzerland assembled at the invitation of the French Post, Telegraph and Telephone Administration This conference proposed that a Consulting Committee should be formed which should undertake to unify as far as possible the practices of the various European telephone administrations bearing on international telephone communication, and should gather statistics and prepare technical recommendations to be submitted to the telephone authorities of the participating countries. Nineteen nations accepted the recommendations of the Paris conference of 1923 and their delegates assembled at Paris the following year to form the International Consulting Committee for Long Distance Telephone Communication A constitution was prepared and a sub-committee appointed to prepare the agenda for the next conference The recommendations of the preliminary conference were considered and some additional matters were discussed, particularly a proposal for a standard transmission unit and proposals relating to rates for international messages.

In 1925 the Consulting Committee held its second meeting, at which representatives of European telephone manufacturers were present. Transmission and inductive interference problems were added to the subjects to be studied. A number of proposals toward bringing the work of the committee into affiliation with similar activities of the League of Nations were rejected owing largely to the fact that Germany, which occupies a strategic position in regard to the system of international telephone communication on the Continent, was not at that time a member of the League. Subsequently the Consulting Committee has adopted the International Telegraph Regulation, as it was amended by the International Telegraph Conference of 1925, as a guide in its activities. Much has been done in the way of developing recommended standards of service and instructions for the operation of international circuits Engineering problems in particular have received exhaustive consideration and much attention has been given to the question of suitable rates and classes of service. Further recogni-

tion of the importance of long distance telephony was accorded by resolutions which were adopted at the 1925 Congress of the International Chamber of Commerce at Brussels, and at the 1927 convention of the same organization at Stockholm.

This recognition of the importance of long distance telephone communication, supplemented by the concrete recommendations of the International Consulting Committee, has helped to stimulate the European telephone administrations to take advantage of recent improvements in telephone equipment, notably as regards the increased efficiency of long distance telephone cables made possible by loading, the development of the vacuum tube repeater and other advances in the telephone art. Long distance telephone cables have been extensively introduced recently in Austria, Belgium, Czechoslovakia, France, Germany, Great Britain, Hungary, Italy, The Netherlands, Sweden and Switzerland.

European Long Distance Cables. *Austria.*—The first long distance cable from Vienna to Passau on the German frontier was finished early in 1927, covering a distance of 170 miles and containing 114 circuits. Austria has a total of nearly 500 miles of long distance telephone cable and at the completion of present plans this mileage will be greatly increased.

Belgium.—Belgium has had telephone communication with London by submarine cable since 1903. The first cable was supplemented by a second in 1911, and a third in 1927. Long distance cables connect the main centres with the French, German and Netherlands frontiers. The complete system comprises nearly 600 miles of large telephone and telegraph cables.

Czechoslovakia.—A total mileage of over 300 miles is now in service or under construction and plans are under way for greatly extending the existing system.

France.—The Paris-Strasbourg cable opened in 1926, is 308 miles long and connects with the German long distance cable system. Additional telephone cables run from Paris to Havre—130 miles, and from Paris to Boulogne—158 miles, the latter forming part of the main line connecting the British and French telephone systems. In 1927, a new submarine cable of 21 circuits was laid across the English Channel. Construction work was begun in 1927 on a 310-mile cable between Paris and Lyons. In all, France has 738 miles of long distance cable in operation, and 370 miles additional under construction.

Germany.—Extension of long distance telephone cables has been very rapid, the network covering the entire country and linking up practically all important centres. Germany, early in 1927, had about 4,600 miles of long distance telephone cables. The cable system connects with the Swiss, Dutch, French, Austrian, Belgian, Czechoslovakian and Polish systems, and a total of 750 miles of submarine telephone cable connects with Scandinavian countries and with East Prussia. The telephone circuit through cable from Berlin to London passes through the Netherlands and is approximately 860 miles in length.

Great Britain.—Four main cable routes centering in London extend, respectively, to Glasgow via Leeds, Newcastle and Edinburgh, to Manchester and Liverpool, to South Wales via Reading and Bristol and to Portsmouth and Southampton. The international telephone connections with America utilizing the radio receiving station at Cupar, Scotland, and the transmitting station at Rugby, also centre at London, messages over the transatlantic circuit to and from either British or Continental points passing through the metropolis. In 1927, Great Britain had long distance telephone cables aggregating well over 6,000 miles. Direct submarine telephone cables connect Great Britain with France, Belgium and Holland, and British telephone users can talk not only with these countries, but also with Germany, Sweden, Norway, Switzerland, Austria, Hungary, Czechoslovakia, Spain, etc.

Netherlands.—The first inter-urban telephone cable in Holland was opened in 1921. The main cities are now connected by means of cables and a cable has been carried eastward to the German border. A submarine cable connects with Great Britain.

Hungary.—A long distance cable connects Budapest with Vienna and further extension of the cable system is planned.

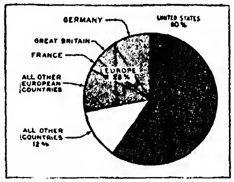
Italy.—In 1924, a long distance cable system totaling 184 miles of cable was opened for service. Extensive expansion of this system is planned together with a submarine telephone cable to the island of Sardinia.

Sweden.—Sweden has a telephone cable 335 miles long connecting Stockholm and Gothenburg. Other cables connecting with the German and Danish systems bring the total length of Swedish long distance cables, including part of the submarine cables, to over 650 miles.

Switzerland.—The Swiss cable network, including more than 1,000 miles of cable, connects the main cities together and by means of connections to the various frontiers provides important facilities for international traffic.

Telephone cable construction in Europe is progressing so rapidly that the gaps in the existing networks are being closed up and already there is a total of 15,152 miles containing 1,692,784 miles of cable pairs in the eleven countries which form a part of the present European long distance telephone cable system.

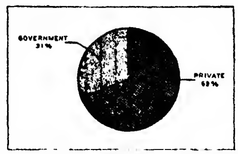
Status of the Telephone Throughout the World, 1929.—Figures 3, 4, 5, 6 and 7 indicate the status of the telephone throughout the world at the latest date for which comprehensive statistics covering practically all countries are available at the time of writing. On January 1, 1928, there were 30,990,304 telephones in service throughout the world, or 1,583,743 more than there were on January 1, 1927. Approximately 60 per cent. of all the telephones in the world on January 1, 1928, were in the United States, the total for that country being 18,522,767. At the same date Europe had 8,623,407 telephones, or about 28 per cent. of the world's total. Of these 2,814,996 were in Germany, about 1,635,000 were in Great Britain and Northern Ireland, and France had approximately 885,000. The remaining telephones were distributed among the countries of Asia, Africa, Oceania, South America and North America outside of the United States. Canada had 1,259,987. Of the remainder 463,810 were in South America, 1,042,399 in Asia (nearly three-quarters of which were in Japan), 203,357 in Africa and 677,727 in Oceania (including somewhat over 442,000 in Australia and about 145,000 in New Zealand).



BY COURTESY OF THE AMERICAN TELEPHONE AND TELEGRAPH CO.

FIG. 3.—DISTRIBUTION OF THE WORLD'S TELEPHONES, JAN. 1928

In proportion to population the United States had, at the date to which these figures relate, 15·8 telephones per one hundred people. The world as a whole had at the same date 1·6 telephones for every one hundred inhabitants. At the beginning of 1928 Canada had 13·2 telephones per hundred people. New Zealand had 10·0 and Denmark 9·3. Sweden had 7·7, Australia 7·2, Hawaii 7·0 and Norway 6·4. Germany, at the same date, had 4·4 telephones per one hundred people and the corresponding figure for Great Britain and Northern Ireland was 3·6, for France 2·2, and for Italy 0·7.



BY COURTESY OF THE AMERICAN TELEPHONE AND TELEGRAPH CO.

FIG. 4.—OWNERSHIP OF THE WORLD'S TELEPHONES, JAN. 1928

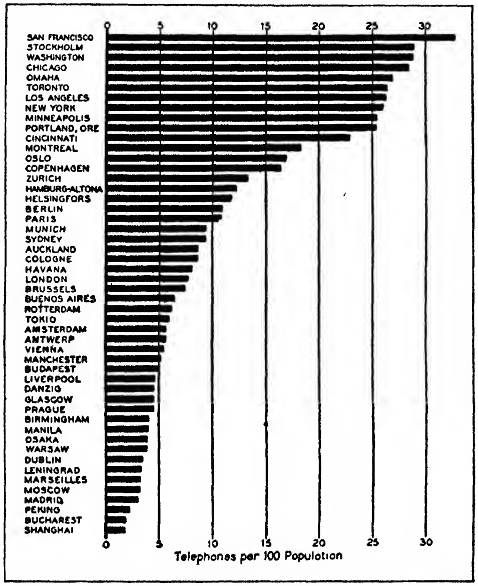
The United States has, however, not always been in advance of Europe in number of telephones. In 1885, about ten years after the telephone's birth, there were, to be sure, 155,700 telephones in the United States, or almost twice as many as in Europe. Nevertheless, by the beginning of 1892 Europe had attained a total of 254,900 telephones, which placed it ahead of the United States where there were then only 239,300 telephones. Europe maintained its lead over the United States in telephone totals by a comfortable margin for nearly seven years thereafter, but in the latter part of 1898 the United States again passed Europe and the margin of American leadership has been widening ever since. As will be noted from the tables, the United States has at present considerably more than twice as many telephones as Europe.

Among the South American nations Argentina had a develop-

ment of 2·2 telephones per hundred people at the date to which these statistics relate.

Japan had attained a development of 1·2 telephones per 100 people by the beginning of 1928.

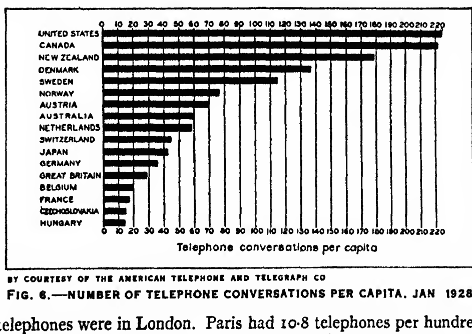
As regards the distribution of telephones with respect to the size of communities, it may be said that in general the smaller communities in the United States had a larger portion of the



BY COURTESY OF THE AMERICAN TELEPHONE AND TELEGRAPH CO.

FIG. 5.—TELEPHONES PER 100 POPULATION OF LARGE CITIES, JAN 1928

total telephones than was the case in Europe. As a rule, the most intensive use of the telephone in countries outside of North America was to be found in the large cities. A third of all the French telephones were in Paris and a third of all the British



BY COURTESY OF THE AMERICAN TELEPHONE AND TELEGRAPH CO

FIG. 6.—NUMBER OF TELEPHONE CONVERSATIONS PER CAPITA, JAN 1928

telephones were in London. Paris had 10·8 telephones per hundred people and London had 7·7 at the date to which these figures relate. New York at the same time had 26·1 telephones for every one hundred inhabitants, Chicago 28·4, and Los Angeles 26·3. San Francisco had 32·8. Stockholm had 28·9 per one hundred inhabitants. Copenhagen had 16·4, Oslo 16·9 and Malmo 13·6. Toronto, Canada, had 26·4 telephones per one hundred people, Berlin had 10·9, Frankfort-on-Main had 11·4 and Hamburg-Altona had 12·2 Tokio had 5·8 telephones for every one hundred population, Wellington, N.Z., had 13·4 and Havana, Cuba, had 8·1.

In respect to telephone conversations during the year 1927, the latest period for which comparative data covering various countries are available, the United States had a total of 26,200,000,000 The figures for telephone conversations include both local and toll, or long distance, conversations. So far as they relate to the

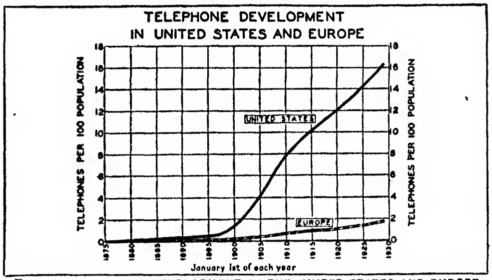


FIG 7.—TELEPHONE DEVELOPMENT IN THE UNITED STATES AND EUROPE

United States they cover completed messages only Americans, during the year 1927, used the telephone 224·7 times per capita, while Canada was next with 221·5 conversations per capita There were 178·9 telephone conversations per person in New Zealand, 136·8 in Denmark, 114·6 in Sweden and 76·2 in Norway during the same period Germany had a total of 35·5 telephone conversations per capita during that year Great Britain and Northern Ireland had 28·6 and France had 17·2 In Austria there were 69·5 telephone conversations per person during the year, in Australia there were 59·6 and in the Netherlands 58·4

Much has already been accomplished toward the integration of telephone communication facilities not only in countries like the United States, Canada, Sweden and elsewhere, but also in regard to international communications on the North American and European continents and by the transatlantic radio circuit between America and Europe. The day is probably still far distant when anyone anywhere in the world can communicate by telephone with anyone else anywhere in the world Progress in extending the range of telephone communication during the past few years has brought this ideal measurably nearer to accomplishment. Present indications point to further progress at an accelerated pace

TELESCOPE, an optical instrument employed to view distant objects (Gr. τῆλε, far, σκοπεῖν, to see). The name was adopted by Galileo as early as 1612; it came into English use much later, supplanting the terms *trunk* and *cylinder* which were used at first.

Early History.—The telescope was invented in Holland about 1608. The credit has been attributed variously to three individ-

uals. Hans Lippershey and Zacharias Jansen, spectacle-makers in Middleburg, and James Metius of Alkmaar (brother of Adrian Metius, the mathematician). The common story is that Lippershey, happening one day whilst holding a spectacle-lens in either hand, to direct them towards the steeple of a neighbouring church, was astonished on looking through the nearer lens to find that the weathercock appeared nearer. Accordingly he fitted the lenses in a tube to preserve their relative distance and thus constructed the first telescope. From the archives at The Hague it appears that on Oct. 2, 1608, the assembly of the States-general considered the petition of Hans Lippershey, inventor of an instrument for seeing at a distance. On Oct. 4 a committee was appointed to test the instrument, and on Oct. 6 the assembly voted 900 florins for it. Further, on Dec. 15 they examined a binocular instrument made by Lippershey at their request, and ordered two such instruments at 900 florins each; but, as many other persons had knowledge of this new invention to see at a distance, they did not deem it expedient to grant him the exclusive right to sell such instruments. A petition by Metius (to whom the invention is attributed by Descartes) was presented to the States-general on Oct. 17 of the same year. He stated that he had discovered the instrument by accident when engaged in experiments, and had so far perfected it that distant objects were made as visible and distinct as by the instrument lately offered to the States-general by Lippershey.

Telescopes were made in considerable numbers and found their way over Europe soon after their invention. Galileo, in his *Nuncius Siderius*, states that, happening to be in Venice about May 1609, he heard that a Belgian had invented a perspective instrument for making objects appear nearer and larger, and that he discovered its construction by considering the effects of refraction. The day after his return to Padua he made his first telescope by fitting a convex lens in one end of a leaden tube and a concave lens in the other end. A few days afterwards having succeeded in making a better telescope than the first, he took it to Venice, where he communicated the details to the public, and presented the instrument itself to the doge Leonardo Donato, sitting in full council. The senate, in return, settled him for life in his lectureship at Padua and doubled his salary, which was previously 500 florins and which then became treble that which any of his predecessors had enjoyed. Galileo devoted all his time to improving and perfecting the telescope. He conquered the difficulties of grinding and polishing the lenses, and soon succeeded in producing telescopes of greatly increased power. His first telescope magnified three diameters; but he soon made instruments which magnified eight diameters, and finally one that magnified thirty-three diameters. (This last power is as great as can advantageously be employed with non-achromatic lenses.)

With this last instrument Galileo discovered in 1610 the satellites of Jupiter, and soon afterwards the spots on the sun, the phases of Venus, and the hills and valleys on the moon. He demonstrated the rotation of the satellites of Jupiter round the planet, and gave rough predictions of their configurations, proved the rotation of the sun on its axis, established the general truth of the Copernican system as compared with that of Ptolemy, and fairly routed the fanciful dogmas of the philosophers. These brilliant achievements, together with the immense improvement of the instrument under the hands of Galileo, overshadowed in a great degree the credit due to the original discoverer, and led to the universal adoption of the name of Galilean telescope for the form of instrument invented by Lippershey.

In the Galilean telescope the object-glass is a convex lens and the eye-piece concave. Kepler was the first to explain the theory and some of the practical advantages of a convex eye-piece in his *Catoptrics* (1611). The first person who actually constructed a telescope of this form was the Jesuit, Christoph Scheiner, who gives a description of it in his *Rosa Ursina* (1630). William Gascoigne pointed out one great advantage of the form of telescope suggested by Kepler; viz., the visibility of the image of a distant object simultaneously with that of a small material object placed in the common focus of the two lenses. This led to his invention of the micrometer and his application of telescopic sights to astronomical instruments of precision. It was not till about the middle of the 17th century, however, that Kepler's telescope came into general use, and then, not so much because of the advantages pointed out by Gascoigne, but because its field of view was much larger than that of the Galilean telescope. The first powerful telescopes of this construction were made by Huygens, after much labour, in which he was assisted by his brother. With one of these, of 12 ft. focal length, he discovered the brightest of Saturn's satellites (Titan) in 1655, and in 1659 he published his *Systema Saturnium,* in which was given for the first time a true explanation of Saturn's ring, founded on observations made with the same instrument.

The sharpness of image in Kepler's telescope is very inferior to that of the Galilean instrument, so that when a high magnifying power is required it becomes essential to increase the focal length. G. D. Cassini discovered Saturn's fifth satellite (Rhea) in 1672 with a telescope of 35 ft. and the third and fourth satellites in 1684 with telescopes made by Campani of 100 and 136 ft. focal length. Huygens states that he and his brother made object-glasses of 170 and 210 ft. focal length, and he presented one of 123 ft. to the Royal Society of London. Adrien Auzout (d. 1691) and others are said to have made telescopes of from 300 to 600 ft. focus, but it does not appear that they were ever able to use them in practical observations. James Bradley, on Dec. 27, 1722, actually measured the diameter of Venus with a telescope whose object-glass had a focal length of 212¼ feet. In these very long telescopes no tube was employed, and they were consequently termed *aerial* telescopes.

Reflecting Telescopes.—It was not until the middle of the 18th century that these unwieldy instruments were supplanted by the achromatic telescope. Meanwhile the refracting type of telescope had a rival in the reflecting telescope invented by Sir Isaac Newton. It was in fact Newton who discovered what was the trouble with the refractor, which led to the need for excessive length. It had been supposed that the only imperfection in the image arose from the error known as spherical aberration, and the efforts of opticians were concentrated on devising lenses of suitable forms of curvature to correct this. In 1666 Newton discovered the different refrangibility of light of different colours, and he soon perceived that the fault of the refracting telescope was that the light of different colours followed different paths; so that if, for example, the telescope was focused sharply for blue light—the green image would be altogether out of focus and blurred. He over-hastily concluded from rough experiments (*Optics,* bk. i. pt. ii. prop. 3) "that all refracting substances diverge the prismatic colours in a constant proportion to their mean refraction." If this were true no combination of refracting substances could bend the path of the light without introducing colour, and therefore no improvement could be expected in the refracting telescope. He therefore turned his attention to the construction of reflectors. The form now known as the Gregorian reflector had already been proposed by James Gregory in 1663; but he had not succeeded in constructing the instrument practically.

Newton, after much experiment, selected an alloy of tin and copper for his specula, and he devised means for grinding and polishing them. He did not attempt the formation of a parabolic figure on account of the probable mechanical difficulties, and he had besides satisfied himself that the chromatic and not the spherical aberration formed the chief fault of previous telescopes. Newton's first telescope so far realized his expectations that he could see with its aid the satellites of Jupiter and the horns of Venus. Encouraged by this success, he made a second telescope of 6½ in. focal length, with a magnifying power of 38 diameters, which he presented to the Royal Society in Dec. 1671. A third form of reflecting telescope was devised in 1672 by Cassegrain. No further practical advance appears to have been made in the design or construction of the instrument till the year 1723, when John Hadley (best known as the inventor of the sextant) presented to the Royal Society a reflecting telescope of the Newtonian construction, with a metallic speculum of 6 in. aperture and 62⅝ in. focal length, having eye-pieces magnifying up to 230

diameters. The instrument was examined by Pound and Bradley, the former of whom reported upon it in *Phil. Trans*, 1723.

Bradley and Molyneux, having been instructed by Hadley in his methods of polishing specula, succeeded in producing some telescopes of considerable power, one of which had a focal length of 8 ft; and, Molyneux having communicated these methods to Scarlet and Hearn, two London opticians, the manufacture of telescopes as a matter of business was commenced by them. However, it was reserved for James Short of Edinburgh to give practical effect to Gregory's original idea. Born at Edinburgh in 1710 and originally educated for the church, Short attracted the attention of Maclaurin, professor of mathematics at the university, who permitted him about 1732 to make use of his rooms in the college buildings for experiments in the construction of telescopes. In Short's first telescopes the specula were of glass, as suggested by Gregory, but he afterwards used metallic specula only, and succeeded in giving to them true parabolic and elliptic figures.

Achromatic Telescopes.—The historical sequence of events now brings us to the discovery of the achromatic telescope. The first person who succeeded in making achromatic refracting telescopes seems to have been Chester Moor Hall, a gentleman of Essex. He argued that the different humours of the human eye so refract rays of light as to produce an image on the retina which is free from colour, and he reasonably concluded that it might be possible to produce a like result by combining lenses composed of different refracting media. After devoting some time to the enquiry he found that by combining lenses formed of different kinds of glass the effect of the unequal refrangibility of light was corrected, and in 1733 he succeeded in constructing telescopes which exhibited objects free from colour.

The principal development of the achromatic refractor is due to John Dollond who invented it independently (*Phil Trans*, 1758). In principle his object-glasses were of the pattern mainly used at the present day; viz, convex lens of crown glass combined with a concave lens of flint glass. The concave lens is of less power than the convex, so that the combination converges the light as a single convex lens would do, but the flint glass having much wider difference of refractive index for light of different colours, is able to correct the colour dispersion introduced by the more powerful crown lens. A triple objective, consisting of two convex lenses of crown glass with a concave lens of flint glass between them, was introduced in 1765 by Peter, son of John Dollond. This type is also employed in some modern telescopes.

The subsequent improvement of both reflecting and refracting telescopes has been mainly a matter of technical detail in the making, figuring, and mounting of large lenses and mirrors. At present the largest refractor has an aperture of 40 in (Yerkes observatory), and the largest reflector an aperture of 100 in. (Mt. Wilson observatory). A limit to the aperture of refractors is set by the difficulty of casting large enough discs of glass of the necessary transparency and homogeneity; moreover, if this were overcome, we should ultimately reach a point at which the strain on the lens caused by its own weight would spoil its optical qualities. The size of reflectors appears to be limited only by consideration of expense, not only of making the mirror, but of providing a mounting for its practical use. Funds have been provided for the construction of a reflector of 200 inches aperture, and it is expected that the instrument will be built in the course of a few years. Pictures of typical modern telescopes are given in the plate illustrating the article OBSERVATORY. Introductory remarks on the general use of astronomical telescopes will be found under ASTRONOMY: *Practical Astronomy*.

THEORY OF THE TELESCOPE

It is important to realize that magnifying power is not the only quality, perhaps not even the chief quality, desired in a telescope. We have to pay attention to (1) magnifying power, (2) resolving power, (3) light-grasp, (4) a wide field of good definition, and (5) suitability for making accurate measurement. Not all of these can be developed to perfection in the same instrument, and accordingly telescopes of different design are employed for different purposes. For example, the ordinary field-glass is useless for viewing the stage in a theatre; and accordingly an opera-glass is employed which gives a more brilliant though smaller image.

In general, resolving power and magnifying power go together. It is little use making the object appear larger if we do not at the same time sharpen the image so that greater detail may appear. We might be content to increase the resolving power (*i.e*, sharpen the detail in the image) without magnification if that were possible; but optical laws forbid an increase of resolving power without a corresponding increase of magnification. The magnifying power of a telescope can be understood by reference to the theory of geometrical optics alone; to explain the increase of resolving power, reference must be made to physical optics (the wave-theory of light). Light does not consist of strictly linear rays, but of a wave disturbance which tends to spread and blur any image that is being formed; this tendency to spread is not cured by any perfecting of the figures of the lenses and mirrors, but only by increasing the aperture so that a wider area of wave-front is taken in and concentrated into the eye-pupil. The resolving power of a telescope (free from ordinary optical defects) is simply proportioned to the diameter of aperture of the object-glass or mirror. But in order that the beam filling the object-glass may be narrowed down on emergence from the telescope so as to enter the eye, the magnifying power must be not less than the ratio of the aperture of the telescope to the aperture of the eye-pupil; if lower power is used an outer ring of the object-glass is left unused so that its effective aperture and resolving power are reduced. In looking for faint nebulae we should like to use the large object-glass merely to concentrate more light, and not to dissipate the light again by enlarging the image which it forms; this, however, is impracticable because we cannot effectively use the full aperture of the object-glass without employing a corresponding magnification. For this reason comparatively little progress in our knowledge of nebulae can be made by visual observation, and most of the work is done by photography.

Refracting Telescopes.—In its simplest form the telescope consists of a convex lens (object-glass) which forms an image of a distant object at its focus. This image is then magnified by another small lens (eye-piece) which is used just as an ordinary magnifying glass is used. The object-glass is of long focus F, and the eye-piece of short focus f, and the ratio F/f, is equal to the magnifying power of the telescope. Since eye-pieces are inexpensive it is usual to provide a number of them, so that different magnifying powers can be used; it may be noted that the smallest eye-pieces have the highest power.

The combination just described is Kepler's form of telescope. The course of the rays is shown in fig. 1. In Galileo's form the eye-lens is concave (or negative), and is placed so as to intercept the rays from the object-glass before they reach the focus (fig. 2). This form is common in binoculars for terrestrial observation, because it gives an erect image, whereas in Kepler's telescope objects are seen upside-down unless a second erecting eye-piece is added. In stellar observation we do not much mind the inversion of the image and Kepler's form is always preferred.

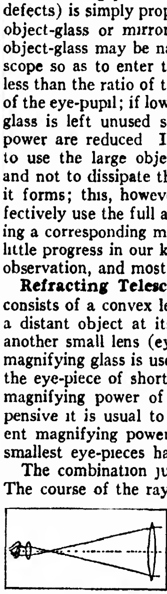

FIG 1.—DIAGRAM SHOWING COURSE OF RAYS WHEN THE EYE-LENS IS CONVEX (OR POSITIVE)

In all modern instruments both the eye-piece and object-glass are compound, consisting of at least two lenses. A single eye-lens would generally give good enough definition at the centre of the field of view, but all the outer parts would be out of focus. Two well-known types of double eye-piece, the Huygens and the Ramsden eye-piece, give a large flat field of view. The construction of eye-pieces for the telescope and for the microscope is essentially the same problem. (*See* MICROSCOPE.) The use of two lenses in the object-glass is necessary in order to correct the defect of colour dispersion already mentioned. In spite of improvements in the manufacture of optical glass, practically the same crown and flint glasses as those used by John Dollond in 1758 are employed in the largest modern telescopes. Owing to what is termed "irrationality of dispersion" no combination of crown and flint lenses will completely get rid of colour dispersion.

In some of the newer glasses the irrationality of dispersion has been reduced to a minimum, but they have nothing approaching the same difference of dispersive power as the ordinary crown and flint glass (a difference of 1 to $1\frac{2}{3}$); deeper curves and thicker lenses would be required, which would neutralize all the advantages of using them. Accordingly in practice the achromatism is made as perfect as possible for the part of the spectrum that will chiefly be employed; viz., near the yellow light for visual work, and in the blue and ultra-violet for photographic work. For this reason separate telescopes are used for visual and photographic work, respectively.

By using three lenses to form the object-glass photo-visual telescopes can be made, sufficiently achromatic for all parts of the spectrum. The additional surfaces and thickness of glass, however, involve some loss of light; and the combination has the great drawback that its focal length changes very rapidly when the temperature drops at nightfall.

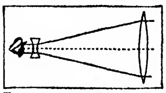

FIG. 2.—DIAGRAM SHOWING COURSE OF RAYS WHEN THE EYE-LENS IS CONCAVE (OR NEGATIVE)

Reflecting Telescopes.—The following are the various forms of reflecting telescopes:

The Gregorian telescope is represented in fig. 3. *A A* and *B B* are concave mirrors having a common axis and their concavities facing each other. The focus of *A* for parallel rays is at *F*, that of *B* for parallel rays at *f*—between *B* and *F*. Parallel rays falling on *AA* converge at *F*, where an image is formed; the rays are then reflected from *B* and converge at *P*, where a second and more enlarged image is formed. Gregory himself showed that, if the large mirror were a segment of a paraboloid of revolution whose focus is *F*, and the small mirror an ellipsoid of revolution whose foci are *F* and *P* respectively, the resulting image will be plane and undistorted. The image formed at *P* is viewed through the eye-piece at *E*, which may be of the Huygenian or Ramsden type. The practical difficulty of constructing Gregorian telescopes of good defining quality is very considerable, because if spherical mirrors are employed their aberrations tend to increase each other, and it is extremely difficult to give a true elliptic figure to the necessarily deep concavity of the small speculum. Short appears to have systematically conquered this difficulty, and his Gregorian telescopes attained great celebrity. The use of the Gregorian form is, however, practically abandoned.

The Cassegrain telescope differs from the Gregorian only in the substitution of a convex hyperboloidal mirror for a concave ellipsoidal mirror as the small speculum. This form has two distinct advantages: (1) if spherical mirrors are employed their aberrations have a tendency to correct each other; (2) the instrument is shorter than the Gregorian, *caeteris paribus*, by twice the focal length of the small mirror. For spectroscopic purposes the Cassegrain form has peculiar advantages, because in consequence of the less rapid convergence of the rays after reflection from the convex hyperboloidal mirror, the equivalent focus can be made very great in comparison with the length of the tube. This permits the employment of a spectroscope furnished with a collimator of long focus.

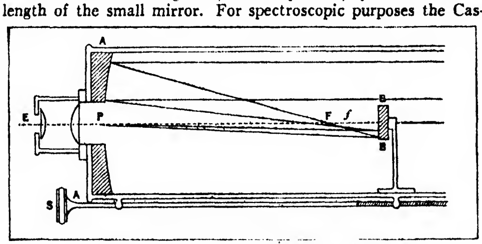

FIG. 3.—DIAGRAM OF THE GREGORIAN TELESCOPE

The Newtonian telescope is represented in fig. 4. *A A* is a concave mirror whose axis is *aa*. Parallel rays falling on *AA* converge on the plane mirror *BB*, and are thence reflected at right angles to the axis, forming an image in the focus of the eye-piece *E*. The surface of the large mirror should be a paraboloid of revolution, that of the small mirror a true optical plane. When used for photography the inclined mirror is removed; and the photographic plate is supported in a carrier mounted at the principal focus of the large mirror.

Most modern reflectors are made so that they can be used alternatively in the Cassegrain or Newtonian form by inserting alternative small mirrors. In the earlier reflectors the mirrors were made of metal. The art of making specula was notably developed by Sir William Herschel, who may be said to have created the fame of the reflector. His greatest telescope, made in 1789, was of 4 ft. aperture and 40 ft. focal length. In 1845 Lord Rosse erected the Parsonstown reflector of 6 ft. aperture. These suffered from the great drawback that whenever the mirror became tarnished, the re-polishing was likely to spoil the figure of the mirror. To preserve the quality the figuring must be done all over again, and the telescope became virtually a new instrument with different optical behaviour. In modern practice the reflecting surface is a film of silver deposited on a glass disc ground to the proper curvature. When the surface loses its brilliance the silver film is washed off (once or twice a year) and a new film deposited.

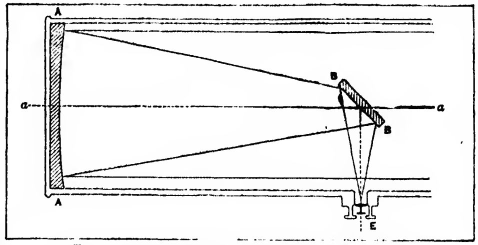

FIG. 4.—DIAGRAM OF THE NEWTONIAN TELESCOPE

Photography.—When a photograph is to be taken the eye-piece is removed and the photographic plate is placed in the focal plane of the object-glass or mirror. It is not a question of adding a camera to a telescope, but of turning the telescope into a camera, the main lens or mirror of the telescope acting as the lens of the camera. In visual observation it is no great drawback if the definition falls off in quality towards the outside of the field of view, because the observer cannot pay minute attention to more than one object at a time; but in astronomical photography it may be a great advantage to have objectives giving good definition over a wide field many degrees in diameter. This makes severe demands on the skill of the designer in correcting the various aberrations of the lens system, which usually increase rapidly with the distance from the centre of the field of view. In general, a *doublet*, consisting of two similar pairs of lenses separated by a wide interval, is employed. The problem of constructing these wide-angle lenses is essentially the same as that of constructing a good camera lens for terrestrial photography (where a wide field is also necessary); and indeed a good portrait lens can be usefully employed in celestial photography. The fact that the whole instrument is of insignificant size is irrelevant when *speed* and not *magnification* is the main essential. As is well-known in terrestrial photography the speed depends on the ratio of the aperture to focal length, and not on the absolute dimensions of either; and this ratio can be made greater in a doublet than in an ordinary refractor or reflector. For detecting faint diffuse light (*e.g.*, the limits of the tail of a comet, or the extended nebulosity in Orion or in the Pleiades) an instrument the size of a hand camera is more effective than a 100 in. telescope.

Mounting.—If a telescope is kept fixed, the stars in their apparent diurnal rotation pass rapidly across the field of view. Hence for most purposes a telescope should be mounted in such a way that it can automatically "follow" a star. This is contrived by an "equatorial" mounting. Fig. 5 shows the so-called English form. *AA* is the "polar axis," which is parallel to the axis of the

earth's rotation, and therefore elevated at an angle equal to the latitude of the observatory. By rotating the whole instrument about this axis the effect of the earth's rotation is precisely counteracted, and the telescope remains pointing in the same absolute direction in space, *i.e.*, to the same star. The necessary rotation about *AA* is given by a driving-clock. The telescope tube is also free to turn about a "declination axis" at right-angles to *AA*, so that it can be pointed to objects of higher or lower declination; the declination is read off on the graduated circle *BB*. *DD* is a similar circle for reading the right ascension or hour-angle.

The English mounting had generally been considered rather antiquated, and all modern instruments were made on a plan which (although the same in principle) avoided the necessity of supporting the polar axis at its upper end; but its reputation is perhaps rehabilitated by the fact that it was found necessary to revert to it for the 100 in. reflector at Mt. Wilson.

An important adjunct to an equatorial mounting is the driving-clock. For visual work no great perfection is required, but for photography it is essential that the image should remain fixed at one point on the plate throughout the exposure. For this purpose the rate of the driving-clock is first controlled by a mechanical governor, which keeps it approximately steady. Then there is an electrical control, which puts in an accelerating or retarding mechanism, according as the clock is ahead of or behind current signals coming once a second from a freely swinging pendulum. Finally, since no automatic control can compensate for the changing displacements by refraction as the object rises or descends in the sky, the ultimate correction is made by hand. The observer watches a star seen in a parallel guiding telescope (or by some equivalent device); and whenever he detects a tendency to drift away from the original position marked by cross-wires he brings it back by a hand-control.

TWO LARGE TELESCOPES

The following are some details of the two largest telescopes at present existing (*See* photographs in article OBSERVATORY.)

The Mount Wilson Telescope.—The diameter of the mirror is 100·4 in. (255 cm.), the focal length 42·3 ft. (12·89 metres). The tube of the telescope is swung in a split polar axis, the cross pivots on which the tube rotates serving as the declination axis. The great weight of the telescope (100 tons) is carried by large drums situated at the upper and lower ends of the polar axis, which float in troughs of mercury, while the actual direction of the axis is determined by self-aligning spherical bearings near its two extremities. The telescope can be used either in the Newtonian or Cassegrain form, separate terminal sections of the tube being

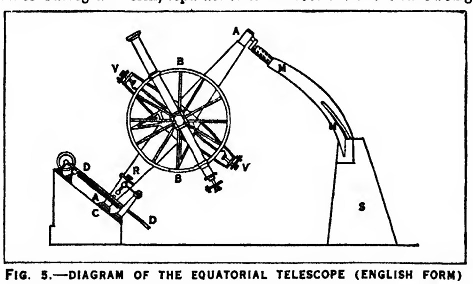

FIG. 5.—DIAGRAM OF THE EQUATORIAL TELESCOPE (ENGLISH FORM)

provided as carriers for the auxiliary mirrors of each. These carriers, or "cages" as they are called, are very massive, and are removed and exchanged with the aid of an electric crane. When it is necessary to remove the mirror for silvering, which is about twice a year, it is lowered by means of a large hydraulic jack into a laboratory just beneath the floor. Two large tubes lying parallel to the telescope contain weights that can be moved longitudinally to perfect the balance. The instrument is provided with quick and slow motion devices operated electrically, and essentially all movements of it and of the dome are accomplished by motors under independent control by the observer at the eye end and the assistant at the desk. Forty motors are used in the dome. The mirror is supported by a counterpoise system. In order to minimize the effect on the mirror of changes in the temperature of the air, it is surrounded by an insulating sheath of cork-board. Means were originally provided for keeping the mirror cell jacketed with brine, which was automatically held at a constant temperature, but they were eventually discarded and reliance was placed on the

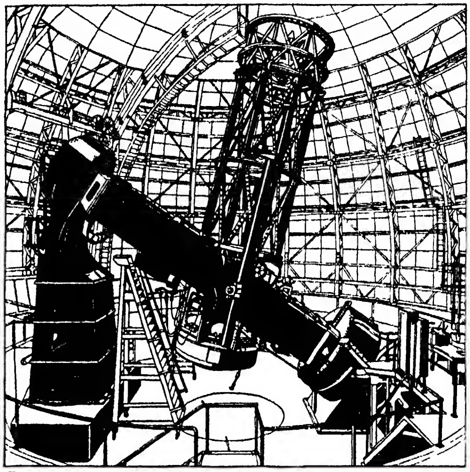

FIG. 6.—ONE-HUNDRED INCH REFLECTING TELESCOPE WITH CASSEGRAIN SPECTROGRAPH OF MOUNT WILSON OBSERVATORY, CALIFORNIA, AT THE TIME OF ITS CONSTRUCTION THE LARGEST IN THE WORLD

cork insulation as well as on the protective covering of the dome.

The Victoria Telescope (British Columbia).—The diameter of the mirror is 72·5 in. (184·15 cm.) the focal length 30·1 ft. (9·180 metres). Critical features of this telescope are the polar axis bearings and the construction of the tube. The polar axis rotates in ball bearings of large size, unrelieved by supporting or flotation devices. This departure from usual practice in the construction of large telescopes has proved very successful. The lattice-work part of the tube is built as a unit, without removable end pieces such as those of the Mt. Wilson telescope, provision being made for the direct interchange of the Cassegrain mirror, the Newtonian mirror and the focal plane apparatus without the removal of a terminal section of the tube. The telescope is electrically operated.

A new telescope, 200 inches in diameter, will soon be under construction, which will be double the size and have four times the light-gathering power of the reflector on Mount Wilson, California, at present (1929) the largest in the world. A half billion stars that cannot now be seen by any telescope will be revealed. Funds for the cost of this telescope will be provided by the International Education Board, which administers Rockefeller benefactions, and the instrument will be under the control of the California Institute of Technology. When completed it will be used to extend present researches in spectrum photography of the stars, direct photography of faint celestial objects, investigation of the nature of spiral nebulae and in radiometry.

REFERENCES.—Special forms of telescope (other than equatorials) are treated under TRANSIT CIRCLE and ZENITH TELESCOPE. *See* also OBSERVATORY, where illustrations are given. TELESILLA, Greek poetess, a native of Argos, one of the so-called nine lyric muses. According to the traditional story, when Cleomenes, king of Sparta, invaded the land of the Argives in 510 B.C., and slew all the males capable of bearing arms, Tele-

silla, dressed in men's clothes, put herself at the head of the women and repelled an attack upon the city of Argos. Of Telesilla's poems only two lines remain, quoted by Hephaestion, apparently from a Parthenion, or song for a chorus of maidens.

TELESIO, BERNARDINO (1509–1588), Italian philosopher and natural scientist, was born of noble parentage at Cosenza near Naples in 1509. He was educated at Milan by his uncle, Antonio, himself a scholar and a poet of eminence, and afterwards at Rome and Padua. He began his attack upon the mediaeval Aristotelianism which then flourished in Padua and Bologna. Resigning to his brother the archbishopric of Cosenza, offered to him by Pope Pius IV., he began to lecture at Naples and finally founded the academy of Cosenza. In 1565 appeared his great work *De natura rerum iuxta propria principia,* which was followed by a large number of scientific and philosophical works of subsidiary importance. A short time after his death, at Cosenza in 1588, his books were placed on the Index.

Telesio was the head of the great South Italian movement which protested against the accepted authority of abstract reason, and sowed the seeds from which sprang the scientific methods of Campanella and Bruno, of Bacon and Descartes, with their widely divergent results. He proposed an inquiry into the data given by the senses, from which he held that all true knowledge really comes. Instead of postulating matter and form, he bases existence on matter and force. This force has two opposing elements: heat, which expands, and cold, which contracts. These two processes account for all the diverse forms and types of existence, while the mass on which the force operates remains the same. The harmony of the whole consists in this, that each separate thing develops in and for itself in accordance with its own nature while at the same time its motion benefits the rest. The obvious defects of this theory, (1) that the senses alone cannot apprehend matter itself, (2) that it is not clear how the multiplicity of phenomena could result from these two forces, and (3) that he adduced no evidence to substantiate the existence of these two forces, were pointed out at the time by his pupil, Patrizzi. (*See* article on PATRIZZI, FRANCESCO.) His system is a forerunner of all subsequent empiricism, scientific and philosophical, and marks clearly the period of transition from authority and reason to experiment and individual responsibility. Beside the *De Rerum Natura,* he wrote *De Somno, De his quae in aere fiunt, De Mari, De Cometis et Circulo Lacteo, De usu respirationis,* etc.

TELESPHORUS, bishop of Rome from about 126 till about 137. St. Irenaeus says that he suffered martyrdom.

TELETYPESETTER, a new invention to set type by telegraph. It operates automatically either a linotype or intertype typesetting machine and will considerably increase production. It is estimated that one man can easily operate four or five of them when controlled by teletypesetters. From one transmitting distributor, type will be set on any number of typesetting machines situated in any place that can be reached by telegraph. It will be valuable also in newspaper offices and in printing plants for purely local work where the tape can be perforated and sent to the composing room to operate the typesetting machines. On the receiving end in newspaper offices a mechanical printer can be operated simultaneously for typewriting the message. In the printing of books, the rolls made by the teletypesetter can be used as a permanent record, making unnecessary storing of metal plate.

The teletypesetter is made of three units: sending, receiving and typesetting. At the sending station the apparatus consists of a perforator, a counter and a transmitting distributor. The perforator, resembling a portable typewriter, produces a tape with coded perforations which the distributor changes into electrical impulses. The receiving apparatus is made up of a reperforator and a printer, the purpose of the latter being to enable the receiver to read the matter transmitted. Beyond the reperforator are the transmitting distributor, through which the tape runs to be changed into electrical impulses, the selecting units, with magnets to operate the typesetting machine, and a panel box, containing relays to control the machine and furnish power to operate the automatic elevator.

Experiments are under way to make the teletypesetter typewrite the message on the tape at the same time that it perforates it. Also, it is being attempted to operate by radio a teletype which automatically records typewritten matter. The development of the teletypesetter is credited to Frank E. Gannett, Walter W. Morey and the Morkrum-Kleinschmidt Corporation. (J. C. Os.)

TELEVISION, by virtue of usage, has come to mean the transmission, to a distant point, usually by electrical means, of moving scenes, to be viewed at the distant point practically simultaneously with their original occurrence. Television is thus differentiated from the viewing of distant events by a telescope, from the electrical transmission of still pictures, and from the projection of motion pictures from films transported to a distance.

Analysis of the Problem.—The problem of electrical television consists essentially in the transformation of light into electrical signals, the transmission of these signals to a distant point and the recreation of light from them. If these three processes can be carried out with adequate speed and accuracy, the transmission of complete moving images may be attained. The process of creating electrical signals from light, transmitting these signals and producing light at the receiving end is a comparatively simple matter if a single light signal is all that is required. In the case of image transmission, however, it is necessary to transmit not one but a vast number of signals in a very brief time. Any image or picture may be considered as made up of a very large number of small areas or elements each of uniform brightness. When an image is viewed by the eye, the rods and cones of the retina perform this analysis of the image into small elements and the many fibrils of the optic nerve simultaneously transmit to the brain the impulses set up by light in each of the rods and cones. It would be theoretically possible to build a television system in which a large number of photosensitive cells were simultaneously exposed to an image and a separate electrical circuit connected with each one carried the electrical signals to a distant point where again a bank of lamps was controlled by the signals. Such a multi-channel scheme is not, however, practical, and all successful methods of television have resorted to a process of *scanning,* by means of which the

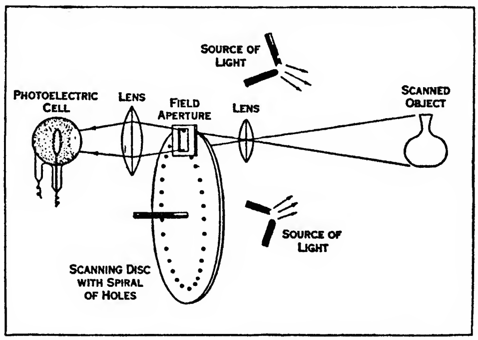

FIG. 1.—DIAGRAM ILLUSTRATING DIRECT SCANNING OF AN IMAGE FOR TELEVISION

whole of an image is traversed point by point and the signals corresponding to the various degrees of light and shade are transmitted *in sequence* instead of simultaneously. This is the same device which is used in the electrical transmission of still pictures, and the essential difference between still picture transmission which may take several minutes and television, is that in the latter the entire image must be traversed in a small fraction of a second (about $\frac{1}{20}$) in order that, through persistence of vision, the image when reconstructed may appear complete and may change its character with sufficient rapidity so that motion

of the object viewed may be reproduced without flicker or jerkiness.

Scanning Apparatus.—Various devices such as vibrating mirrors and rotating discs have been proposed for the rapid scanning of an image for television purposes. The means which thus far has been found most practical is a flat circular disc provided with a spiral of small holes. By the rotation of this

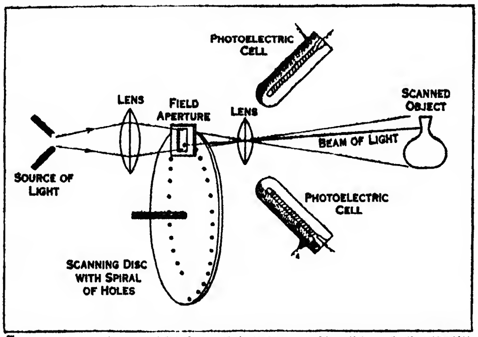

FIG. 2.—DIAGRAM ILLUSTRATING TELEVISION SCANNING BY THE "BEAM" METHOD. THE OPTICAL PATH IS REVERSED, AS COMPARED WITH THE DIRECT SCANNING METHOD SHOWN IN FIG 1

disc each hole of the spiral passes in turn across the field of view, so that at each complete rotation of the spiral, the whole image has been covered The most straightforward way of utilizing such a disc is shown in fig 1, where an image of the scene to be transmitted is projected by means of a lens upon an aperture in front of the disc of such size and shape that only one hole of the disc is at any time exposed to the image. If such a disc is rotated 15 to 20 revolutions per second, the image transmitted through the holes appears virtually complete and steady, although the image is actually built up of a sequence of light signals.

Transformation of Light into Electrical Signals.—In order to produce electrical currents for transmission purposes, from the light passing through the scanning disc, use is made of some light sensitive device. This light sensitive device must be extremely rapid in its action and should if possible give currents of a magnitude acceptable for transmission over ordinary transmission channels such as a telephone line For this purpose earlier experimenters used selenium which, however, is relatively sluggish in its response. More recently in the most successful experiments on television, a photo-electric cell has been used This consists of a glass tube on whose inner wall is a layer of alkali metal such as potassium. The tube may be evacuated or may be filled with an inert gas such as argon at low pressure. The incidence of light on the sensitive surface causes the emission of electrons, thus producing an electrical current which in the case of properly designed photo-electric cells is not only practically instantaneous but is directly proportional to the intensity of the light

Photo-electric currents suffer from the disadvantage that they are excessively minute when excited by the illumination available from an ordinarily illuminated object. It is necessary to amplify the photo-electric current by means of vacuum tube amplifiers before such currents are available for transmission purposes It is in fact largely owing to the development of vacuum tube amplifiers, that it has been possible to bring television to a successful stage. Even, however, when using image-forming lenses of the largest light gathering power, it is necessary for the original object to be very brilliantly illuminated if the method of image formation and scanning shown in fig. 1 is to be utilized. It has only recently been possible, by constructing the television apparatus of large dimensions, whereby more light can be utilized, and by the development of very sensitive photo-electric cells, to utilize this "direct" method of scanning, with objects in the relatively intense illumination of outdoor daylight. An alternative method of scanning which utilizes the available light much more efficiently is the method of "beam" scanning. In this (fig. 2) the relative positions of the photo-electric cell and the light sources as shown in fig. 1 are reversed, and a narrow beam of light is projected through the hole in the scanning disc and traverses the object rapidly from side to side. The light reflected from the object is then picked up by photo-electric cells, which may be made of very large area so as to collect the maximum amount of light. The beam method of scanning is applicable to indoor scenes where the objects may be close to the scanning apparatus. The method of direct scanning is suitable for outdoor scenes in sunlight.

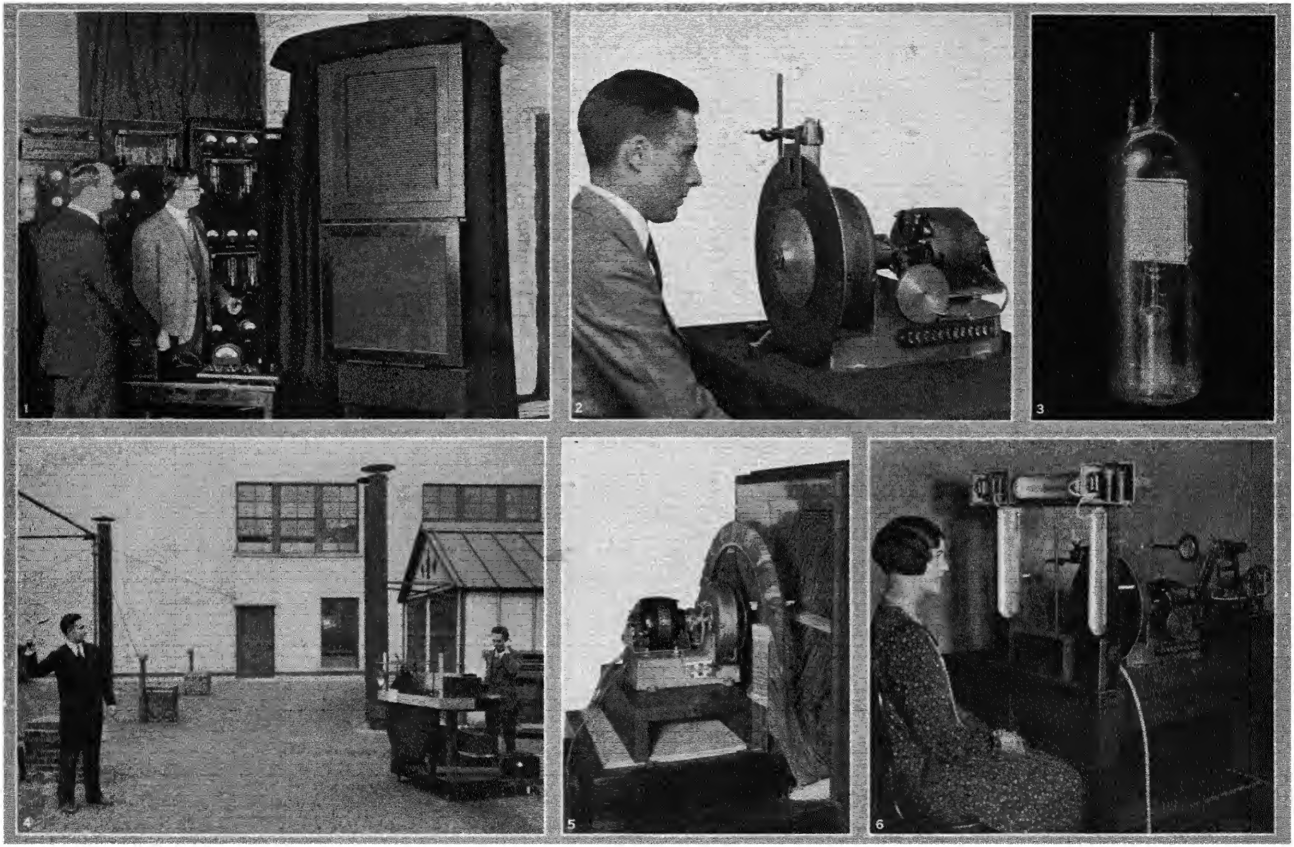
A practical exemplification of the direct method of scanning is shown in Plate fig. 4 where a scanning disc of 3 ft. diameter containing a spiral of 50 scanning holes is utilized to produce television signals from a full length human figure. Plate fig. 6 shows in skeletonized form a practical exemplification of apparatus for the beam method of scanning. Here the light from an arc lamp is condensed upon the back of a scanning disc which carries a spiral of 50 holes, and a narrow beam of light is projected by means of a lens to the face of the sitter. Three large photo-electric cells collect the reflected light and the photo-electric currents thus produced are amplified by means of vacuum tube amplifiers close to the cells. Subsequent amplification to the order of several thousand million-fold raises these currents to sufficient size for transmission over an ordinary electrical communication channel.

Transmission.—The problem of transmitting television signals presents considerable difficulty for the reason that an exceedingly wide band of frequencies must be transmitted without distortion. The nature of the problem may be comprehended by considering a typical case. If the image to be transmitted is scanned by a disc apparatus having 50 holes, the analysis of the entire image corresponds to dividing it into 50 by 50 or 2,500 elements. In order to create the illusion of continuity the image must be completely scanned about 20 times a second. This means that signals corresponding to 50,000 elements per second must be transmitted. In terms of alternating current frequencies, this means approximately 25,000 cycles per second. Now speech transmission by the telephone is successfully accomplished by a frequency band of approximately 2,000 cycles and the best radio broadcasting stations occupy bands not over 5,000 cycles in width. It is, therefore, obvious that the transmission of a relatively crude image corresponding in quality to considerably less than a square inch of newspaper halftone requires transmission facilities of extraordinary quality. In addition to extreme width of transmission frequency band, this band must extend to frequencies much below those necessary for speech, and all parts of the transmission band must be in proper phase relation with each other

The transmission of television signals may be accomplished either over wire or wireless channels In the case of wire transmission, it has been found most practical to transmit the television signals directly, utilizing a channel which transmits from below 20 cycles per second up to the highest frequency called for by the degree of resolution of the image. In radio transmission, the television signals are placed upon an appropriate high frequency carrier in the usual manner. In either case, the lowest frequencies—below the repetition frequency of the images—to which are due the general brightness of the picture, are not transmitted, this element of picture quality being arbitrarily inserted as a direct current component at the receiving end. This expedient is resorted to because of the serious technical difficulty of amplifying and transmitting very low frequencies.

In the case of wire transmission, the system must be reasonably free from interference such as produces what in voice transmission is called "noise," which in the case of television causes specks or streaks obscuring the image. In the case of wireless transmission, there are additional sources of trouble, particularly those associated with fading and multiple reflection of wireless signals in the Heaviside layer. These latter produce multiple images whose prominence varies with the distance and time of day, and for which as yet no remedy has been found.

Reception of the Image.—The simplest method of recon-



EXPERIMENTAL RECEIVING AND SENDING EQUIPMENT OF TELEVISION

1. Receiving apparatus. Scenes are reproduced on screen formed by a continuous neon tube in upper foreground. Lower screen conceals a loud-speaker for reproducing the sounds accompanying the scene
2. Watching a television image. The perforated disc, revolving 18 times per second, has 50 holes passing the aperture in the square plate, so that the viewer sees the cathode plate of a neon lamp
3. Neon glow lamp whose brightness varies to produce the illusion of a picture
4. Apparatus for transmission of outdoor scenes. It has larger scanning disc than indoor apparatus and one photoelectric cell which serves as the eye in television
5. Rear view of grid receiver of fig. 1, showing motor which rotates in exact synchronism with sending disc, the distributor and wires leading to the 2,500 external electrodes of the neon tube
6. Apparatus for television—scanning by the "beam" method

structing the image from the television signals consists in the use of a disc with a spiral of holes at the receiving end similar to that at the sending end. Combined with this is a light source, which can be viewed through the disc, which will follow faithfully the variations in strength of the incoming signals. The most successful light source for this purpose is a neon glow lamp furnished with a large flat electrode which when placed behind the disc fills the whole field of view. In the Plate, fig. 2 is shown this arrangement of disc and neon lamp and in the Plate, fig. 3 a neon lamp of a type commonly used. As the observer watches the rapidly rotating disc, he sees at any instant a bright point of light which is of the intensity corresponding to the incoming signal. This in turn corresponds to the photo-electric current generated at the sending end, that is, to the brightness of the image on the sending disc. Due to persistence of vision, the observer is conscious only of a completely illuminated field differing in brightness in its different elements. If the receiving disc is rotating at exactly the speed of the sending disc and exactly in phase with it, the image seen at the receiving end is similar to that at the sending end.

Apparatus of the sort just described is suitable for viewing only by a single individual. Apparatus by which the received image may be observed by a large audience is shown in the Plate, fig. 1. In place of the small neon lamp with a single electrode, a lamp composed of 50 straight parallel glass tubes is utilized. Each tube is furnished with 50 electrodes and the incoming electrical signals are transmitted to each of these electrodes in turn by the distributing device shown in the Plate, fig. 5. Here again, by persistence of vision, the whole area of the grid of neon tubes appears to be continuously illuminated and the image is developed by the varying intensity of the glow at each electrode.

Synchronization.—In order that the scanning and receiving means which have been described shall faithfully reproduce the scene, it is essential that the speed of operation of the two ends shall be identical to a high degree of accuracy. Thus with the two 50 hole discs, which have been taken as typical, if a hole at the receiving end is not to shift from its proper position by more than half its diameter, which is a reasonable restriction, the disc must not move from its proper position during rotation by the distance it travels in about a hundred thousandth part of a second. Deviations from the proper speed produce motion and distortion of the received image. The necessary accuracy of synchronization has been achieved by the use of synchronous motors with a large number of poles operated by relatively high frequency signals. These high frequency signals (2,000 cycles per second) may be generated by a vacuum tube oscillator, or by light received by an auxiliary photo-electric cell from holes or reflecting spots in the disc. The synchronizing signals may be transmitted either over a separate communication channel or, as has been proved practical, may be produced by piezo electric crystal oscillators separately operated at the two ends.

Applications and Problems.—A number of applications of television are suggested by considering parallel cases of sound transmission. In sound we have the use of the telephone for conversation between individuals, the use of loud speaking equipment for carrying speeches to large audiences (*see* Plate, fig. 1) and finally, broadcasting equipment for transmitting voice or music to receiving equipment in homes. We can similarly imagine television equipment to be used in connection with the telephone, in connection with displaying public speakers or athletic events to audiences at a distant point or for the broadcasting of scenes into homes.

At the present time (1928), while all of these possibilities have been experimentally demonstrated, the practical difficulties of transmitting really satisfactory images are so great as to impose a very serious obstacle to the rapid general use of television. The number of image elements which is necessary for the transmission of a complicated scene is excessively large. While a single face may be recognizably rendered with 2,500 elements, the amount of detail shown in the very coarsest newspaper halftones of new events demands 100,000 or more elements. While with sound the same apparatus and transmission channel will handle a chorus as well as a solo, in television the complexity of apparatus and width of transmission channel both increase with the number of performers. The transmission of the human face requires the equivalent of something like ten telephone channels for each direction of transmission, while the transmission of an extended scene in any detail would require transmission facilities equivalent to that of a very large number of radio broadcasting stations. Transmission channels of whatever sort have a money value, compared to which the value of the addition of sight to sound in communication must be soberly estimated. The technical problems encountered in the sending and receiving apparatus also increase greatly with the complexity of the images, so that unless totally new methods of image analysis and synthesis are developed, the apparatus to handle extended scenes must be exceedingly costly. In view of these considerations the likelihood of early wide-spread use of television appears problematic.

Historical.—The general principles by which television might be accomplished have been recognized for a long time. Nipkow in 1884 patented the now generally used disc with its spiral of holes, which he proposed to use in front of a selenium cell. All suggestions of this sort were, however, abortive until the advent of the current amplifying devices which have been developed in the last decade for telephone and radio. Apparatus utilizing spirals of lenses or holes, capable of developing electrical currents from images and reconstructing luminous images from the electrical current was exhibited by several experimentors as early as 1925, notably by C. F. Jenkins in America and J. W. Baird in England. The first complete public demonstration of television involving not only the terminal apparatus for the analysis and synthesis of images, but the actual transmission of the signals to great distances (Washington to New York city) was made by the American Telephone and Telegraph Company in April 1927. Transmissions of images across the Atlantic, and in colour were announced by Baird in 1928. In the same year several radio stations in the United States initiated the broadcasting of crude images of faces and other simple objects. Many technical problems have yet to be solved before television can claim to be more than an interesting novelty and it remains for the future to disclose what its field of utility will be. (H. E. I.)

TELFORD, THOMAS (1757–1834), British civil engineer, was the son of a shepherd, and was born at Westerkirk in Eskdale, Dumfriesshire, on Aug. 9, 1757. From early childhood he was employed as a herd, occasionally attending the parish school of Westerkirk. At 15 he was apprenticed to a stone-mason. He studied in his spare time, and published verses from time to time in the local press. In 1780 Telford went to Edinburgh, where he was employed in the erection of houses in the "new" town, and in 1782 was employed in the erection of Somerset House, London. In 1793 he was appointed engineer of the Ellesmere canal, for which he built the Chirk and Pont-y-Cysyllte aqueducts, and this work established his reputation as a canal engineer.

Telford was commissioned by the British Government to report on the improvement of communications in the Highlands of Scotland. He was appointed engineer for the Caledonian canal begun in 1804, and for the construction of 920 m. of roads, a great part through very difficult country. He was also employed on the improvement of the road between Carlisle and Glasgow, on plans for a system of roads through the more inaccessible parts of Wales, which included the magnificent suspension bridge across the Menai Straits, begun in 1820, and the Conway bridge, begun in 1822. The fisheries and industries of Scotland benefited by the improvements he effected at many of the harbours on the east coast; he constructed the St. Katherine's Docks, London (finished in 1828); and his last piece of professional work was a plan for the improvement of Dover harbour. Other achievements of his later years were the drainage of the north level of the eastern Fen district, an area of 48,000 ac., and erection of the Dean bridge, Edinburgh, and of the Broomielaw bridge, Glasgow. He died on Sept. 2, 1834, in London, and was buried in Westminster Abbey.

See Telford's *Memoirs*, written by himself and edited by John Rickman (1838); also Smiles's *Lives of the Engineers*.

TELL, WILLIAM. The story of William Tell's skill in

shooting at and striking the apple which had been placed on the head of his little son by order of Gessler, the tyrannical Austrian bailiff of Uri, is so closely bound up with the legendary history of the origin of the Swiss Confederation that they must be considered together. Both appear first in the 15th century, probably as results of the war for the Toggenburg inheritance (1436–50); for the intense hatred of Austria, increased by her support of the claims of Zürich, favoured the circulation of stories which assumed that Swiss freedom was of immemorial antiquity, while, as the war was largely a struggle between the civic and rural elements in the Confederation, the notion that the (rural) Schwyzers were of Scandinavian descent at once separated them from and raised them above the German inhabitants of the towns.

The Tell story is first found in a ballad the first nine stanzas of which (containing the story) were certainly written before 1474. It is probably to this ballad that Melchior Russ of Lucerne (who began his *Chronicle* in 1482) refers when he excuses himself from giving the story. He narrates how Tell then stirred up his friends against the governor, who seized him and took him by boat to his castle on lake Lugano. A storm arose, and Tell, on account of his great strength, was given the rudder, on his promise to bring the boat to land. He steers it towards a shelf of rock, called in Russ's time Tell's Platte, springs on shore, shoots the bailiff dead with his cross bow, and returning to Uri, stirs up the strife which ended in the battle of Morgarten. In these two accounts, which form the basis of the Uri version of the origin of the Confederation, it is Tell who is the leader. We first hear of the cruelties of the Austrian bailiffs in the Forest districts in the *Bernese Chronicle* of Conrad Justinger (1420), who makes no allusion to Tell. The Tell story and the "atrocities" story are first found combined in a ms. known as the *White Book of Sarnen.* They are contained in a short chronicle written between 1467 and 1476, probably about 1470, and based on oral tradition.

The task of smoothing away inconsistencies and rounding off the tale, was accomplished by Giles Tschudi (*q.v.*), whose recension was closely followed by Johannes von Müller in his *History of the Confederation* (1780). The final recension of Tschudi's *Chronicle* (1734–36), which differs in many particulars from the original draft preserved at Zurich, tells how Albert of Austria, in order to deprive the Forest lands of their ancient freedom, sent bailiffs (among them Gessler) to Uri and Schwyz Their tyranny resulted in a rising, planned at the Rütli, on Nov. 8, 1307, and led by Werner von Stauffacher of Schwyz, Walter Fürst of Uri, Arnold von Melchthal in Unterwalden, each with ten companions, among whom was William Tell, to expel the oppressors. On Nov. 18 the Tell incident takes place (described according to the *White Book* version), and on Jan. 1, 1308 the general rising. Tschudi thus finally settled the date, which had before varied from 1260 to 1334. He distorts the historical circumstances. In his first draft he speaks of the bailiff as Gryssler —the usual name up to his time, except in the *White Book* and in Stumpff's *Chronicle* of 1548—but in his final recension he calls him Gessler, knowing that this was a real name. Later writers added a few more particulars. Johannes von Muller (1780) described the oath at the Rütli by the three (Tell not being counted in), and threw Tschudi's version into a literary form. Schiller's play (1804) gave the tale a world-wide renown

The general result of the researches of various students, J. E. Kopp, Vischer, Rochholz and others, has been to show that a mythological marksman and an impossible bailiff bearing the name of a real family have been joined with confused and distorted reminiscences of the events of 1245–47, in which the names of many real persons have been inserted and many unauthenticated acts attributed to them. Th. von Liebenau has, however, shown (in an article reprinted from the *Katholische Schweizerblatter* in the *Bollettino Storico della Svizzera Italiana* for 1899) that in 1283 the Emperor Rudolf of Habsburg gave the right of receiving the tolls for escort over the St Gotthard Pass to his sons, the dukes of Austria. The levying of these tolls gave rise to various disputes between the men of Uri and the bailiffs of the dukes of Austria, and by 1319 (if not already in 1309) the claim to levy them was silently given up. These facts show (what could not hitherto be proved) that at the time when legend places the rising of Uri, Tell exploit, etc., the dukes of Austria really had disputes with Uri.

The alleged proofs of the existence of a real William Tell in Uri in the 14th century break down hopelessly. (1) The entries in the parish registers are forged. (2) As to the Tell chapels—(*a*) that in the "hollow way" near Küssnacht was not known to Melchior Russ and is first mentioned by Tschudi (1572). (*b*) That on Tell's Platte is first mentioned in 1504. The document which alleges that this chapel was built by order of a "landsgemeinde" held in 1388, at which 114 men were present who had been personally acquainted with Tell, was never heard of till 1759. The procession in boats to the place where the chapel stands may be very old, but is not connected with Tell till about 1582. (*c*) The chapel at Bürglen is known to have been founded in 1582.

In general *see* two excellent works by Franz Heinemann, *Tell Iconographie,* Lucerne, 1902 (reproductions, with text, of the chief representations of Tell in art from 1507 onwards), and *Tell Bibliographie* (including that of Schiller's play), published in 1908 at Bern. *See* also W. Vischer, *Die Sage von der Befreiung der Waldstätte* (Leipzig, 1867); E. L. Rochholz, *Tell und Gessler,* with a volume of documents 1250–1513 (Heilbronn, 1877); and P. Lang, *Die Schweiz. Tellspiele* (1924). (W. A. B C.; X.)

TELLICHERRY, a seaport of British India, in the Malabar district of Madras, on the Madras railway, between Cannanore and the French settlement of Mahe. Pop. (1921) 27,576. It is a healthy and picturesque town, built upon a group of wooded hills running down to the sea, and is protected by a natural breakwater of rock. Ships are able to anchor 2 miles from the shore. A pier and sea-wall have recently been built and the port can be used during the monsoon season. Tellicherry was at one time defended by a strong mud wall and the old fort still stands to the north of the town. The East India Company established a factory here in 1683 for the pepper and cardamom trade. For two years (1780–82) the town withstood a siege by Hyder's general, and in the subsequent wars with Mysore Tellicherry was the base of operations for the ascent of the Ghats

TELLURIUM, a chemical element and the third member of the sulphur and selenium family (symbol Te, atomic number 52, atomic weight 127·5). It is a complex element having three isotopes (*q v*) with atomic weights 126, 128 and 130. Tellurium is a brittle, silvery white, metallic substance of specific gravity 6·27; it melts at 452° C and boils at 1,390° C; its hardness is 2·3 (Mohs). It crystallises in hexagonal-rhombohedral prisms and is isomorphous with the stable grey modification of selenium (*q.v*). Tellurium was first recognised as a distinct element in 1798 by M H Klaproth, although it had already attracted the notice of mineralogists and metallurgists who on account of its peculiar properties termed it "aurum paradoxum" or "metallum problematum." It is widely distributed although in small amounts. Rarely found native as metallic tellurium, it more generally occurs in combination with metals in such minerals as sylvanite, $(Au,Ag)Te_4$, petzite, $(Au,Ag)_2Te$, tetradymite, $Bi_2(Te,S)_3$, and telluric ochre, TeO_2 The red tellurium sulphur of Japan contains 99·76% S, 0·17% Te, 0·06% Se and 0·01% As. Tellurium minerals are found in Germany, Colorado, California, Ontario, Mexico, South America and West Australia, often accompanying gold deposits. The chief sources of tellurium are the slimes from copper and lead refineries and the flue dusts from telluride gold ores. The slimes contain both tellurium and selenium, and similar processes are used in the extraction of both elements. The slimes from copper refining contain more selenium, those from lead yield more tellurium. The dusts or slimes are fused with sodium carbonate and nitrate, the melt being lixiviated with water. The alkaline liquors containing sodium tellurite and selenite are cautiously acidified with sulphuric acid when tellurium dioxide is precipitated The dioxide may be reduced in the dry way with powdered charcoal or dissolved in hydrochloric acid and reduced with sulphur dioxide, when tellurium is precipitated. Further purification is effected by dissolving tellurium in dilute nitric acid (sp.gr. 1·255) and crystallising the basic nitrate, $2TeO_2,HNO_3$.

Applications.—Despite the labours of the chemical research school at Wisconsin University, no extensive use has been found for tellurium, although comparatively large supplies are available, it being estimated that in the U.S.A. alone 125,000 lb. of the metal could be produced without material alterations in existing plants. Most of the output is sold to makers of wireless equipment, since metallic tellurium has some merit as a rectifier or crystal detector. A noteworthy application was the addition of diethyl telluride to motor spirit as an anti-knock material, but although effective this substance has been superseded by lead tetraethyl (*see* Lead, Compounds of; Organo-metallic Compounds: *Fourth Series*). Colloidal tellurium has been suggested as an insecticide and fungicide in wood preservation. To a limited extent tellurium has been employed in colouring glass or porcelain, developing brown, blue or red shades. Acid solutions of the dioxide have been used as a dip for silver ornaments, giving a "platinum finish" to the metal. Soluble tellurium compounds are utilised in toning baths in photography. Tellurium and compounds have been tested therapeutically without marked success.

Physical Properties.—Tellurium is a poor conductor of heat and electricity and the latter property varies only slightly with change of illumination. Its electrical resistance of 200,000 microhms per cubic centimetre is the highest of any metal. Its yellow vapour has a density corresponding with the molecular formula Te_2. Allotropy (*q.v.*) is far less definite than with selenium and sulphur. There is an amorphous modification of tellurium, a crystalline variety, and colloidal preparations of tellurium are made by reducing dilute solutions of telluric acid with hydrazine or sulphurous acid with or without protective colloids.

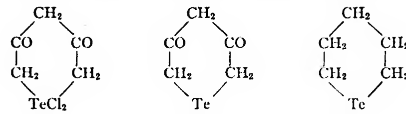
Compounds.—Hydrogen telluride or telluretted hydrogen, H_2Te, is a very unstable gas with a repulsive odour; its boiling point is 0° C and it melts at −48° C. It is best prepared by decomposing aluminium telluride, Al_2Te_3, with water or dilute hydrochloric acid. Tellurium furnishes two chlorides, both prepared by direct combination of the metal with chlorine. The dichloride, $TeCl_2$, is a brown amorphous mass which melts indefinitely to a black liquid boiling at 327° C. The tetrachloride, obtained with excess of chlorine, is a snow-white, crystalline mass melting at about 220° and boiling at 380° C. It is hydrolysed by water. Similar compounds are formed with bromine.

Tellurium dioxide is a white crystalline mass produced by igniting telluric acid or by oxidising tellurium with nitric acid; it becomes yellow on heating, melts at dull red heat and distils in a vacuum at bright red heat. It is only slightly soluble in water but is amphoteric, dissolving in either aqueous acids or alkalis. Tellurium trioxide, an orange-yellow, crystalline substance, is left on igniting telluric acid at a red heat. Telluric acid, $H_2TeO_4,2H_2O$, a snow-white crystalline powder, is made by oxidising tellurium or its dioxide with either chromic acid or chlorates.

ORGANIC DERIVATIVES OF TELLURIUM

The dialkyl tellurides are prepared by distilling potassium telluride with the salts of alkyl sulphuric acids. Dimethyl telluride, a liquid of repulsive odour, boils at 82° C. It is probably the origin of the unpleasant garlic odour noticed in the breath and perspiration of patients or animals treated with tellurium or tellurium compounds. Diethyl telluride, the proposed anti-knock compound, boils at 137·5° C. When heated together at 80° tellurium and methyl iodide combine to form red dimethyltelluronium di-iodide, $(CH_3)_2TeI_2$, converted by silver oxide into dimethyltelluronium dihydroxide, $(CH_3)_2Te(OH)_2$, a base which on heating yields the complex oxide $(CH_3)_3Te{\cdot}O{\cdot}Te(CH_3){:}O$. This oxide forms two iodides, $(CH_3)_3TeI$ and CH_3TeI_3, which unite together yielding greenish-black spangles of the complex iodide $[(CH_3)_3Te][TeCH_3I_4]$ (H. D. K. Drew, 1929).

By the action of tellurium tetrachloride on acetylacetone and certain of its homologues, a series of cyclic organotellurium compounds have been obtained containing the *cyclo*telluropentane ring. The initial product, *cyclo*telluropentane-3:5-dione dichloride, m.p. 115° C (formula I.), is reduced by alkali bisulphites to *cyclo*telluropentane-3:5-dione (II.) crystallising in golden yellow needles and melting at 182° C (G. T. Morgan and H. D. K. Drew, 1920–1922). The substance and its homologues have outstanding bactericidal properties, even in extremely dilute solutions.



(I.) (II.) (III.)

The condensation of aluminium telluride with pentamethylene *αε*-dibromide gives rise to three cyclic tellurium compounds from which *cyclo*telluropentane (formula III.) can be prepared. This compound, the parent substance of the ketonic series (II.) is a very oxidisable yellow oil (b.p. 82–83°/12 mm.) with disagreeable odour, and gives rise to crystalline dihalides, $C_5H_{10}{:}TeX_2$ (G. T. Morgan and H. Burgess, 1928). When tellurium tetrachloride reacts with acetic anhydride, the product furnishes tellurodiacetic and ditellurodiacetic acids, together with a compound, $CH_2(TeCl_3)_2$, containing no oxygen. This hexachloride on reduction with bisulphite loses all its chlorine and yields ditelluromethane $(CH_2{:}Te_2)_x$, a solid existing in red and black modifications (Morgan and Drew, 1925).

Detection and Estimation.—Tellurium is precipitated by hydrogen sulphide and is separated from selenium owing to the greater facility with which the latter is liberated from its compounds by reducing agents. In strongly acid solutions sulphur dioxide eliminates red selenium but not tellurium. The excess of acid and sulphur dioxide are boiled off; potassium iodide is added, and black TeI_4 is precipitated, redissolving in excess of reagent to K_2TeI_6, from which dark red solution sulphur dioxide now readily precipitates tellurium. Tellurium may be weighed either as such or as the oxide.

Hopkins, *Chemistry of the Rarer Elements* (New York, 1923); G. A. Roush, *The Mineral Industry* (New York, 1916 and annually), containing an epitome of the industrial development of tellurium in the U.S.A. (G. T. M.)

TELPHERAGE. During the World War the Italian Army made extensive use of the telpher (*see* Mono-rails and Telphers) system of transport for fighting in the Alps. It had previously been thought impossible to conduct military operations on the high peaks, but the early days of the war saw whole companies of men clinging hand and foot to the rocky summits. The building of roads could not always meet the requirements of troops operating in Alpine districts. Wire railways or "telphers" were provided, thus economising time, labour and oil, and avoiding congestion of roads. These telphers are a kind of suspension railway. A double metal cable called "bearer" is extended on trestles placed in a straight line at different distances on the sides of the mountain. There are two stations, one at the starting point and the other at the end of the line. In one of these stations there is a motor which works an endless cable (the "drawer") to which are fixed two or more small wagons. The cable turns and draws the wagons supported by the "bearer" cable by means of small wheels which run on it.

1. **Telefori.**—These were provisional lines moved by man power and used in the most advanced zones to supply isolated posts or trenches. Their average length was 500 metres and each could carry about 50 quintals a day.

2. **Dismountable Teleferiche.**—These were run by motors and were put up in advanced zones. Their average length was from 1,000 to 2,000 metres, and each could carry from 10 to 20 quintals an hour. They could be dismounted and were portable.

3. **Permanent Teleferiche.**—These were run by motors and were fixed. They were employed at some distance from the lines, and reached a maximum length of 8,000 metres. They could carry about 150 quintals per hour. The telphers covered on an average a rise of 650 metres from the starting-point to that of arrival; but in some cases even 1,500. The trestles were often at very great distances from one another and placed on peaks, while the wagons ran over fearful abysses. In the highest regions the lines often

ran at a height of 2,000 to 3,000 metres; a few were installed even at 3,500 metres above sea-level. The telpherage lines laid on the Italian front transported in all 33,000,000 quintals, the load of 330,000 railway trucks

TELPHERS: *see* MONORAILS AND TELPHERS

TELUGU, one of the five great Dravidian languages. The Telugu-speaking peoples are partly subjects of the nizam of Hyderabad and partly under British rule, beginning north of Madras city and extending north-west to Bellary, where Telugu meets Kanarese, and north-east to near Orissa In many respects it occupies an independent position and can be characterized as the only descendant of the Ândhra dialect of Old Dravidian.

See Bishop Caldwell, *Comparative Grammar of the Dravidian Languages,* and *Linguistic Survey of India,* vol iv. (1906).

TEM, a people in north-west Dahomey speaking a language related to Kokomba They live in extended family groups in compounds in villages surrounded by a defensive wall.

TEMBU (Ama-Tembu), a powerful Kaffir tribe, who have given their name to Tembuland, a division of Cape Colony south-west of Griqualand East. They are traditionally descended from Tembu, elder brother of Xosa, from whom most "Kaffirs" claim descent.

TEMENOS, the Greek term in archaeology given to the enclosed sacred area around a temple or sanctuary.

TEMPE, VALE OF, the ancient name of the gorge, through which the river Peneus (mod. Salambria) reaches the sea from the plain of Lower Thessaly. Greek legend attributed this chasm to Poseidon; before it was riven, between Olympus and Ossa, Thessaly was a lake. It is about four and a half miles long, and towards the middle of the pass, where the rocks are highest, the precipices in the direction of Olympus fall steeply to the stream; but those which descend from Ossa are the loftiest, for they rise in many places not less than 1,500 ft from the valley. It was a position easily defended, but has often offered a practicable entrance to Thessaly from the north; a number of castles (of which the ruins still exist) were built at different times at the strongest points The mediaeval road follows sometimes one bank, sometimes the other; the railway is wholly north of the stream. Being still forested, with numerous lateral valleys, the scenery is unusually picturesque for Greece: its beauty was famous in antiquity. Tempe was sacred to Apollo, to whom a temple was erected on the right bank. Every ninth year a sacred mission visited the valley to pluck laurel for the chaplets for the Pythian games

TEMPELHOF FIELD, the airport of Berlin, Germany, was constructed on the site of Tempelhof Military Field soon after the World War. The airport consists of 1,500,000 sq. metres and is admirably situated, being within the city limits. During 1928, 31,547 passengers and 615 tons of freight, baggage and mail were handled through Tempelhof. The airport is provided with numerous hangars, two of which cover an area of about 26,000 sq ft. each The wireless station supplies weather reports from all parts of Europe. Close to this office is the headquarters of the air police, above which is placed the field-control tower, from which all departing and arriving aeroplanes are regulated. There is also a powerful beacon which is visible at a distance of 60 miles. A modern system of lighting has been provided to facilitate night-flying. Every aeroplane landing at or leaving Tempelhof undergoes strict inspection by the air police (*See* AIRPORTS.)

TEMPERA, the name given to the painting processes in which the medium employed is an albuminous, gelatinous or colloidal material Practically, this is equivalent to saying that any painting process in which a vehicle, or binding material, other than oil is employed is tempera.

History.—The earliest known painting was undoubtedly of this nature. The wall paintings of ancient Egypt and Babylon and those of Mycenean Greece, as well as the mummy cases and papyrus rolls in the first named country, were executed in some form of tempera The same is probably true of the wall paintings in Italian tombs.

Yolk of egg, either alone or with the addition of a little vinegar, was the vehicle most generally used, but many other substances were also employed. Among them were the liquid obtained by boiling parchment or the skins of animals in water, which is practically the same thing as using glue. Pliny mentions the use of milk as a medium.

In more modern times it was the medium of the Italian Primitives. Cimabue learnt it from the Greeks, or so says Vasari, and Giotto, Fillipo, Lippi, Ghirlandajo, Botticelli and many others used it for their inspired works. Raphael, Titian and Tintoretto probably used it, at least for under-painting In northern Europe tempera was earlier supplanted by oil than in Italy, but many of the Flemish and German Primitives employed it

Process.—The ground used by Cimabue, Giotto and their compatriots was usually gesso (plaster of Paris) Cennini gives very full instructions for the making of gesso panels. This was a complicated process involving, first, the preparation of the panel of poplar, lime tree or willow wood, of which all the interstices were to be filled with a mixture of size and sawdust The panel was then covered with old linen cloth held in position by more size. On this surface the *gesso grasso,* or heavy plaster of Paris, ground in size, was spread with a spatula The *gesso sottile* or final ground, composed of thoroughly slaked plaster of Paris mixed with size was then applied with a brush

Devotees of tempera painting as practised by the Italians are convinced, not only of its great permanency, but of its peculiar charm To quote Miss Herringham, the translator of Cennini. "There is no doubt that while fresco and tempera produce a decorated space in itself pleasant and figures and other objects can be suggested in slight chiaroscuro (*q v.*) without appearing unfinished or crude, this is not the case in oil painting, which seems incapable of giving that pleasantness to the surface of a wall and requires a completeness in values, tones and tactile qualities which makes the spectator look into the picture and forget the surface Therefore the one art is monumental, where the surface must not be forgotton or obliterated and the other on the whole appears opposed to monumental painting"

Roger E Fry, writing in the *Burlington Magazine* of the charm of classic tempera says "One may sum up the whole question of tempera as a medium by saying that, while it is more difficult than in oil painting to produce any effect at all, it is yet more difficult, almost impossible indeed, to produce with tempera those thoroughly ugly and uninviting surfaces which it requires profound science to avoid in the clayey mixtures of oil paint. Nothing would be likely to have a more restraining and sobering influence on our art than the substitution of tempera for oils as the ordinary medium of artistic expression"

Modern Uses.—Egg tempera, the medium to which both of these laudatory comments apply, is doubtless a most charming medium and an exceedingly permanent one, as demonstrated by the apparently magnificent preservation of many specimens of very great antiquity It does, however, as Fry points out, present many technical difficulties, principally because of its exceedingly rapid drying. "Transitions of colour" says Fry, "must be made by hatched strokes or else by continual laying one thin coat over another until the transition is produced" This was the practice of the early Italians. In these days of "ready mixed" colours, procurable anywhere, there is not much occasion for the keeping alive of the ancient practices Occasionally, however, an artist uses them successfully for current work

In different fields, certain workers do find it desirable to-day to combine dry colours with a tempera medium. For example, commercial illustrators have discovered that it is possible, by the admixture of dry pigment with a gum arabic-glycerine compound, to obtain colour of much stronger intensity—saturation—than can be had in commercial water-colour. This method of working has the advantage that the strength of the prepared colour is within the artist's control. It is also claimed that it is possible to obtain a very even and flat tone and one that, because of the absence of reflections, is particularly adapted to photographic reproduction

Doubtless there are many other forms of artistic endeavour in which use is made of tempera mediums with dry colour, as in some forms of modern fresco, for example, but tempera, in

TEMPERA PAINTINGS OF EARLY, MEDIAEVAL AND MODERN TIMES

1. Head of woman painted on wood with coloured powder mixed with white wax. Graeco Egyptian. In the Louvre. **2.** "Madonna and Child Enthroned" by Giotto (*c.* 1267–1337). Uffizi Gallery, Florence. **3.** "Pallas Taming a Centaur" by Botticelli (1444–1510). Uffizi Gallery. **4.** "Rape of Helen" by Benozzo Gozzoli (*c.* 1424– ?). **5.** "St. Lawrence Enthroned between Saints Cosmos and Damian" by Fra Filippo Lippi (1406–69). **6.** Portrait of Duranty by Hillaire G. E. Degas (1834–1917). Probably is partly done in thin oils with distemper in the dry—*i.e.*, pastel—used for the face. **7.** "The Bridge—Right Bank" by Yarnall Abbott. American contemporary

its modern application is, like oil painting, almost entirely a matter of the use of prepared colours. These are ground by the manufacturers in various colloidal, gelatinous or albuminous vehicles and sold put up in tubes, pans or pots, but, unlike oil, the products of different manufacturers differ so greatly in character as to necessitate completely different techniques. The product of some colourmen is to be used with the addition only of water, while in other varieties the use of prepared "tempera mediums" is necessary. These are, naturally, compounds similar to the vehicles in which the particular colours are ground. It may be noted that ordinary water-colour, show-card colour and the like, are of course, strictly tempera, being ground in gum arabic and glycerine, although water-colour is only characteristic of the tempera medium when used as *gouache* or body colour.

As noted above, the products of different colourmen vary so radically that it is difficult to give any idea of present day tempera technique. In common they all present the quality of opacity; they may be used upon a great variety of surfaces and, in most cases, the permanency of the results depends only upon that of the ground. Due to their opacity, they may be used to very great advantage on dark grounds—a method of painting which has much to commend it. Most of the temperas in the market, however, are subject to the rather serious objection that the colours become lighter in drying.

Except as used for under-painting, tempera painting of to-day is a direct process. Unlike oil the colour usually dries very quickly upon the ground and any alteration of a tone by "painting into" it is difficult to achieve successfully. This directness, this *premier coup* quality, is one of the charms of the medium and also makes it desirable for quick sketching.

Most users of tempera to-day are in the habit of employing it very flatly, frequently in the form of spots or "lozenges," so to speak, of clean colour applied to grounds which vary from grey or brown to black. This technique is highly characteristic of tempera painting as it is found in the water-colour shows of the United States. But some forms of commercial tempera may be used in a manner which approaches oil in appearance and in which the broken quality of a partially mixed tone may be preserved. For this type of painting very little or no medium is used; heavy water-colour paper is employed as a ground and this may be obtained in a variety of tints from white to black.

A number of prominent artists still use tempera as the medium with which to commence paintings which are completed in oil.

Emil Carlsen, one of the most noted of those who employ this technique, uses an absorbent canvas, certain commercial colours and a commercial egg medium. For the first painting he recommends the using of the colour thinly, with water as a medium. This completed, the canvas is allowed to dry for a day or two, is then given one or two coats of tempera varnish A, and again let dry for a few hours. The picture is now given a light wash of the egg tempera medium and the painting is continued, using egg tempera as the medium instead of water. The colours can now be used solidly but it is necessary to lay layer over layer and let them dry between times or the colour will crack. "The result," says Mr. Carlsen, "is an extremely hard and light underpainting, that, if varnished with a good coat of tempera varnish, well dried, will hold up a piece of painting wonderfully and give it more luminosity in the picture's future than any other process."

It will be evident that the art of tempera painting is even more difficult to limit and define than is painting in oil. It is an art the technique of which varied greatly, as did the vehicles employed, even in its classic period, and this is equally true as to the more or less sporadic revivals of the old processes which are employed to-day, while, as to the commercial tempera of the shops, the colours supplied by one manufacturer may possess radically different qualities and call for a totally different technique from those of another manufacturer, and still be equally desirable. But in this very lack of uniformity is an incentive to the artist who is seeking for an individual, a personal technique. Whether he seeks for this in the use of prepared products or in the study and application of the ancient methods he will find in tempera a number of subtle and illusive charms which will well repay him for the search. (*See* also PAINTINGS; OIL PAINTINGS; PAINTS, CHEMISTRY OF.)

TEMPERAMENT, in psychology, means a kind of lasting emotional mood or temper. Some people are habitually cheerful, others are as habitually melancholy, and so on. The oldest known classification of temperaments is considerably over two thousand years old, and the names associated with that classification are still in daily use. It originated with a Greek medical school known as the Hippocratic school (*see* HIPPOCRATES), and was based upon a theory about the varying proportions of four juices (or "humours") in bodies (Latin *temperare* means "to measure"). The four liquids in the body were alleged to be blood, phlegm, black bile and yellow bile. And according as one or other of these four preponderates in the body of a person, there results the *sanguine* temperament (Latin *sanguis*, blood), the *phlegmatic* temperament, the *melancholic* temperament (Gr. *μελαγχολικός*, with black bile), or the *choleric* temperament. The sanguine temperament is quick, predisposed to pleasant emotions, but weak, and inclined to change quickly from one interest to another. The phlegmatic temperament is slow, lacking in vivacity, but calm and strong. The melancholic temperament is predisposed to sad emotions, slow and weak. The choleric temperament is predisposed to anger, and emotionally quick and strong.

In Music.—Temperament is the manner in which the limited number of notes of a keyed instrument are tuned or "tempered," various methods being possible, *e.g.*, unequal temperament, mean-tone intonation and equal temperament. In the case of an instrument tuned in unequal temperament a few keys will be as near as possible to the mathematical ideal of just intonation, but all the other keys will be more or less seriously out of tune.

Thus supposing the key of C to be tuned in just intonation, with G tuned in consequence as a really exact fifth, this same G will not be in tune when it is required to serve, not as the fifth to C, but as, say, the third to E flat or the fourth to D. Hence therefore the adoption as a compromise of the system known as equal temperament, whereby these inaccuracies of intonation are equally distributed over all the keys, with the result that no one key is better than another but all are sufficiently in tune for practical purposes and can be used with equal freedom.

The mean tone system was an unequal temperament that split the difference between the major tone (8: 9) and the minor tone (9: 10). It long had its warm advocates, but finally had to yield to the superior practical advantages of equal temperament.

(*See* HARMONY; KEY; MUSICAL NOTATION.)

TEMPERANCE. The word "temperance," which strictly means moderation, has acquired a particular meaning in connection with intoxicating liquor, and it is here used in that sense.

Historical.—Ever since man in some distant age first discovered that process of fermentation by which sugar is converted into alcohol and carbonic acid, and experienced the intoxicating effects of the liquor so produced, there has been, in a sense, a temperance question. The records of the ancient oriental civilizations contain many references to it, and from very remote times efforts were made by priests, sages or law-givers in India, Persia, China, Palestine, Egypt, Greece and Carthage to combat the vice of drunkenness. But the evil appears never to have been so great or the object of so much attention in the ancient world as in Western countries and our own era. Two circumstances mainly differentiate the modern problem; one is the use of distilled waters or spirits as a beverage, and the other the climatic conditions pre-

vailing in the more northern latitudes which are the home of Western civilization. The intoxicating drinks used by the ancients were wines obtained from grapes or other fruits, and beers from various kinds of grain. These products were not confined to the East, but were known to the ancient civilizations of Mexico and Peru and even to primitive peoples who used the sugar-containing juices and other substances indigenous in their country. In the time of the Romans the barbarians in the north of Europe used fermented liquors made from honey (mead), barley (beer) and apples (cider) in place of grape-wine. All such drinks produce intoxication if taken in sufficient quantity; but their action is much slower and less violent than that of distilled spirits.

Distillation of essences from various substances seems to have been known to the ancients and to have been carried on by the Arabians in the dark ages, but potable spirits were not known until the 13th century. The distilled essence of wine or *aqua vitae* (brandy) is mentioned then as a new discovery by Arnoldus de Villa Nova, a chemist and physician, who regarded it, from the chemical or medical point of view, as a Divine product It probably came into use very gradually, but once the art of distillation had been mastered it was extended to other alcoholic substances in countries where wine was not grown Malt, from which beer had been made from time immemorial, was naturally used for the purpose, and then gin or Geneva spirits and whisky or usquebagh (Irish for "water of life") were added to grape brandy; then came corn brandy in the north and east of Europe, rum from sugar canes in the Indies, potato spirit, and eventually, as the process was perfected, rectified ethyl alcohol from almost anything containing sugar or starch.

The concentrated form of alcohol, thus evolved, for a long time carried with it the prestige of a Divine essence given to it in the middle ages when chemistry was allied to all sorts of superstitions. It had potent properties and was held to possess great virtue. This view is embodied in the name "water of life," and was at one time universally held; traces of it still linger among the very ignorant. Ardent spirit seemed particularly desirable to the habitants of the cold and damp regions of northern Europe, where the people took to it with avidity and imbibed it without restraint when it became cheap and accessible. That happened in England in the early part of the 18th century (*see* LIQUOR LAWS); and out of the frightful results which followed there eventually arose the modern temperance movement. The legislature had been busy with the liquor traffic for more than two centuries previously, but its task had been the repression of disorder; the thing was a nuisance and had to be checked in the interests of public order It is significant that though drunkenness had been prevalent from the earliest times, the disorder which forced legislative control did not make its appearance until after the introduction of spirits.

Intemperance was one of many questions which we can now see were struggling into existence during the latter half of the 18th century, to become the subject matter of "social reform" in the 19th. Like the majority of them it was a question of bodily welfare, of health. A breach had been made in the unthinking traditional belief in the virtue of alcoholic liquor by the experiences referred to; and medical thought, as soon as it began to busy itself with health as distinguished from the treatment of disease, took the matter up In 1804 Dr Trotter, of Edinburgh, published a book on the subject, which was an expansion of his academic thesis written in 1788, Dr. Benjamin Rush, of Philadelphia, a distinguished American physician and politician, who had studied in Edinburgh and London, wrote a striking paper on the same subject in the same year; and very soon after this the organized temperance movement was set on foot in the United States.

Temperance Organization.—In 1808 a temperance society was founded at Saratoga in the State of New York, and in 1813 the Massachusetts Society for the Suppression of Intemperance made its appearance. These seem to have been the earliest organizations, though the device of a pledge of abstinence had been introduced in 1800 The movement made rapid progress mainly under the influence of the Churches. In 1826 the American Society for the Promotion of Temperance was founded in Boston, and by 1833 there were 6,000 local societies in several States with more than a million members. The campaign was, for the most part, directed against the use of spirits only, and the proposal to include all alcoholic drinks in the pledge of abstinence, though adopted by a few societies, was rejected in 1833 by the American society, but accepted in 1836 and retained ever since.

In Europe the earliest organizations were formed in Ireland A temperance club is said to have been started at Skibbereen in 1818, and others followed; but it was in 1829 that the organized movement began to make effectual progress with the formation of the Ulster Temperance Society. By the end of that year there were 25 societies in Ireland and two or three in Scotland In 1830 the movement spread to Yorkshire and Lancashire, and supported a newspaper called the *Temperance Societies' Record,* according to which there were then 127 societies with 23,000 paying members and 60,000 associated abstainers In 1831 the British and Foreign Temperance Society was founded in London with the bishop of London (Blomfield) for president and Archbishop Sumner for one of the vice-presidents This important society, of which Queen Victoria became patron on her accession in 1837, came to an end in 1850, when the whole cause was under an eclipse The most remarkable episode in the temperance campaign at this period was the mission of the Rev. Theobald Mathew, of Cork, commonly known as Father Mathew, the greatest of all temperance missionaries He travelled through Ireland in the years 1838–42 and everywhere excited intense enthusiasm. People flocked to hear him and took the pledge in crowds In 1841 the number of abstainers in Ireland was estimated to be 4,647,000, which is more than the entire population to-day In three years the consumption of spirits fell from 10,815,000 to 5,290,000 gallons This was not all due to Father Mathew, because great depression and distress prevailed at the same time, but he unquestionably exercised an extraordinary influence In 1843 he went to England, where he had less, though still great, success, and in 1850 to America He died in 1856, by which time the cause had fallen into a depressed state in both countries In the United States a flash of enthusiasm of a similar character, but on a smaller scale, known as the Washingtonian movement, had appeared In 1845 a law prohibiting the public sale of liquor was passed in New York State but repealed in 1847; in 1851 State prohibition was adopted in Maine (*see* LIQUOR LAWS).

Since that time the organized movement has embraced both elements, the voluntary and the compulsory, and has combined the inculcation of individual abstinence with the promotion of legislation for the reduction or suppression of the traffic On the whole the latter has predominated, particularly in the United States, where organized agitation has for more than half a century made temperance a political question and has produced the various experiments in legislation of which an account is given in the article on LIQUOR LAWS. In addition to combining the moral and the political elements the modern movement is characterized by the following features: (1) international organization, (2) organized co-operation of women, (3) juvenile temperance, (4) teaching of temperance in schools and elsewhere, (5) scientific study of alcohol and inebriety

(1) International organization appears to have been started by the Order of Good Templars, a society of abstainers formed, in 1851, at Utica, in New York State. It spread over the United States and Canada, and in 1868 was introduced into Great Britain Some years later it was extended to Scandinavia, where it is very strong. Temperance societies had previously existed in Norway from 1836, and in Sweden from 1837; these seem to be the earliest examples on the continent of Europe. The Good Templars organization has spread to several other European countries, to Australasia, India, South and West Africa and South America. There are several other international societies, and international congresses have been held, the first in 1885 at Antwerp. A World's Prohibition Conference was held in London in 1909. It was attended by about 300 delegates from temperance societies in nearly all parts of the world, and resulted in the foundation of an International Prohibition Federation, which embraces every country in Europe with three or four minor exceptions, the United States, Mexico, Argentina, the British self-governing dominions,

India, China, Japan, Palestine, Tunisia and Hawaii.

(2) The organization of women, which has also become international, dates from 1874, when the National Women's Christian Temperance Union was founded at Cleveland in the United States. In 1907 it had branches in every State in the Union and in about 10,000 towns and villages, with an aggregate membership of 350,000. It employs all means, educational and social as well as political, and has exercised great influence in promoting that drastic legislation which characterizes the United States. It has also taken up many other questions relating to women, and has adopted the white ribbon as badge. About 1883 Miss Frances Willard, who had been the moving spirit of the Union, carried the organization of women into other lands and formed the World's Women's Christian Temperance Union, which now possesses branches in some 50 countries.

(3) The inclusion of children in temperance organization goes back to 1847, when a society of juvenile abstainers who had taken the pledge was formed at Leeds; it took the name of Band of Hope. The practice spread, and in 1851 a Band of Hope Union was formed. There are now a number of such unions, for Scotland, Ireland and separate counties in England; the Bands of Hope are said to number 15,000 in all.

(4) The teaching of temperance in schools, which has become a great feature of the moral propaganda, was begun by private effort in 1852, when the late John Hope inaugurated a regular weekly visitation of day schools in Edinburgh. In 1875, at the invitation of the National Temperance League, Sir Benjamin Richardson wrote his *Temperance Lesson Book,* which was adopted by many schools as a primer. In 1889 school-teaching by travelling lecturers was taken up by the U.K. Band of Hope Union, and the example was followed by many other societies, which have spent large sums on itinerant lecturers; and object-lessons on the nature and effects of alcoholic drinks are given to children in the schools. The Church of England Temperance Society carries on similar work and examines children in the subject of temperance, the annual Report for 1926 stating that 20,000 people of all grades and ages came under instruction in the year. Voluntary temperance teaching having grown continuously and become very extensive, the central education authorities took action; in 1906 the Board of Education in Ireland made "Hygiene and Temperance" a compulsory subject in the public schools; in 1909 the English board issued a syllabus of temperance teaching, the adoption of which in elementary schools is optional (a revised edition, which includes the physiology of food also, was issued in 1922); in Scotland also courses of teaching in hygiene and temperance are permissive and have been adopted by many local educational authorities. In the United States compulsory teaching is of much longer standing and more advanced. The question was first taken up by the Women's Christian Temperance Union (*see above*) in 1879; it was believed that by teaching the physiological effects of alcohol to all children the problem of intemperance would be effectually solved, and a systematic political campaign was planned and carried out for the purpose of obtaining compulsory legislation to give effect to this idea. The campaign was successful in New York in 1884, in Pennsylvania in 1885 and subsequently in other States. Laws have now been passed in every State and territory, making anti-alcohol teaching part of the curriculum in the public schools, and tobacco is usually included. School-teaching is compulsory in Canada, except in Quebec and Prince Edward Island, where it is permissive; in France since 1902; in Sweden since 1892, and in Iceland. It is recognized by authority but optional in Australia, South Africa, some provinces of India, Belgium, Finland, Denmark, Norway, Germany, Austria-Hungary and Switzerland. The movement in favour of school-teaching is, which has become widespread, continuously and generally advancing.

(5) The scientific study of the physiology and pathology of alcohol is a very large subject in itself. As has been shown above, the pioneers of the temperance movement were medical men; and though the Churches soon became the chief moving force, doctors have always exercised an influence, and in more recent times since people learnt to bow down to the name of science there has been a marked tendency to have recourse to scientific authority for arguments and support, of which the teaching of temperance as a branch of physiology or hygiene is an illustration. Medical abstinence societies have been formed in England, Germany, Belgium, Holland, Norway, Sweden and Denmark.

Present State of the Movement.—In recent years the temperance movement has grown and spread, but there are no comprehensive figures of its numerical strength. The *Alliance Year Book,* however, contains a directory of societies, which give some idea of its wide distribution. It contains the names of over 600 organizations including local branches in Great Britain alone, embracing religious (54), women's (48) and juvenile societies (47). It further mentions four international organizations, eight in Australia, 12 in Canada, eight in South Africa and nine in the United States; there are, no doubt, central offices. The periodicals enumerated number 37 in Great Britain, mostly monthly, 14 in Australia, nine in Canada, five in India, two in South Africa and eight in the United States.

The Church of England Temperance Society is much the largest. It was founded in 1862, and re-constituted in 1873 on a dual basis of (1) total abstinence, and (2) general promotion of the society's objects, which are (*a*) promotion of habits of temperance; (*b*) reformation of the intemperate; (*c*) removal of the causes which lead to intemperance. It was incorporated in 1907, re-constituted in 1911 and 1921, and recognized by the Church Assembly in 1923. Its activity is many-sided; it carries on an extensive publication department and educational courses, police court and prison gate missions to seamen, travelling vans, and inebriate homes. The King and Queen are its patrons, the archbishops of Canterbury and York its presidents, and the bishop of London its chairman.

The United Kingdom Alliance, founded in 1853, is the chief political fighting organization. Its object is prohibition of the drink trade, but it has adopted the policy of local prohibition by means of the option. It has for many years furnished the "national drink bill," a calculation of the national expenditure on alcoholic liquors. No details of the membership are given, but the expenditure in 1927 was £9,420. Other legislative organizations are the National Temperance League, the British Temperance League, the National United Temperance Council, the National Temperance Federation, the Temperance Legislation League, and others in Scotland, Ireland and Wales. There is also a Royal Army Temperance Association, of which the King is the patron, and a Royal Naval Temperance Society. The National British Women's Total Abstinence Union has 44 county branches. The international societies enumerated are the World League against Alcoholism, the World Prohibitive Federation, the International Orders of Good Templars and the World's Women's Christian Temperance Union.

Effects of the Temperance Movement.—The organized agitation against the abuse and, in most cases, also the use, of alcoholic liquor is a very interesting feature of social life in those countries where it is mainly carried on. These are the United States of America, the British Islands and Dominions, and the northern countries of Europe, particularly Scandinavia and Finland. It is largely a matter of climate. In the wine-producing countries it is either weak or non-existent. In France alcohol means spirits, and that is generally the case on the Continent. In Spain, Portugal and along the Mediterranean there is no need to check drunkenness, because the people are naturally sober. But in the countries first mentioned that is not the case. It is here that the temperance movement is carried on with great energy, and when we come to ask what effect it has had, the enquiry is found to be full of difficulty. Of the societies some rely on moral influence, others aim at legislation, but too often at unattainable legislation. Nevertheless they must be credited with a large part in procuring the very varied and constantly changing mass of legislation dealing with drink; and, so far, the laws must be considered as results.

Consumption.—The following table gives the amount consumed in the United Kingdom per head of population in gallons from 1870 onwards:

Year	Beer	Spirits	Wine	Year	Beer	Spirits	Wine
1870	30.24	0.99	0.49	1916	20 84	0.61	0 22
1875	33 48	1 28	0 53	1917	12.60	0 41	0 15
1880	27 00	1 07	0.46	1918	9 99	0.33	0 25
1885	27 00	0 96	0 38	1919	16 99	0 47	0.41
1890	29 88	1.02	0 40	1920	20 61	0.47	0.32
1895	29.52	1.00	0.37	1921	18 56	0.39	0 24
1900	31 56	1.12	0.38	1922	15 80	0.36	0.26
1905	27 85	0 92	0.28	1923*	17.04	0.33	0 30
1910	26 31	0 65	0 28	1924*	17.96	0 33	0 35
1913	27 76	0 70	0 25	1925*	17 97	0 32	0 36
1914	26 66	0 69	0 23	1926*	17 17	0 29	0 37
1915	22 77	0.76	0.22				

*Great Britain only

The most notable feature in this table is the great change in 1914–26, the years of war and the subsequent period. The World War has, indeed, produced a greater change than any other event throughout the centuries of liquor control Apart from this we notice a fluctuating tendency, with a general downward movement, which is most striking in the spirits column. The rise and fall correspond with the state of trade; consumption always rises with good trade and falls with bad. The year of the greatest consumption is 1875, which marked the close of the most prosperous trading period ever known The years 1885–88 were years of extreme depression, followed by a short rise and later by a longer one, culminating in 1899 This slowly gave way to another depression, which lasted until 1909, when a rise began again But throughout these fluctuations a general downward movement is discernible. The high-water mark is never so high as the previous one, while low-water mark is lower The general decline is due to a change of social habits, to which many causes have contributed—the spread of education, the provision of alternatives to the public-house, the growth of sport and athletics, the example of the higher classes, and the temperance movement

Coming to the World War we find the effects of a drastic and progressive interference with the drink trade The interference operated in three ways: (1) Reduction of the amount available for drinking, (2) raised prices, (3) reduced hours of sale Together with the withdrawal of men for service, these three conditions fully account for the fall of consumption shown in the table from 1914 to 1918, when the lowest point was reached Their subsequent partial relaxation, with the return of men to civil life, accounts for the rise in 1919–20, when a period of temporary prosperity prevailed That consumption remained still far below the level of 1913 was due to the fact that the war time restrictions were relaxed only in part; and to that has since been added a marked depression of trade, notably in 1922, when the consumption of beer, the most tell-tale commodity, fell heavily. In 1921 a new Licensing Act was passed, which embodied certain restrictions. The most important of these were the hours of sale, which had been reduced during the war from 16, 17 and, in London, 19½ to five and one-half; they were now extended to eight and in London to nine, but a break between the morning and evening is retained. At the same time the prices of drink remained unaltered, as affected by the high taxation of 100s. on a barrel of beer and 72s. a gallon on spirits. In the budget of 1923 a remission of 20s. a barrel on beer enabled brewers to lower the price by 1d. a pint. The continued state of comparative sobriety in subsequent years must be attributed to these three conditions: (1) Hours of sale, (2) high prices, (3) the depression of trade

Prevalence of Drunkenness.—The table of convictions for drunkenness corresponds broadly with that of consumption. The following figures are taken from the licensing statistics of the Home Office·

England and Wales Convictions for Drunkenness

Year	Convictions	Year	Convictions
1905	207,171	1910	161,992
1906	199,014	1911	172,130
1907	197,064	1912	182,592
1908	187,803	1913	188,877
1909	169,518	1914	183,828

England and Wales Convictions for Drunkenness—Cont'd

Year	Convictions	Year	Convictions
1915	135,811	1921	77,789
1916	84,191	1922	76,347
1917	46,410	1923	77,094
1918	29,075	1924	79,082
1919	57,948	1925	75,077
1920	95,763	1926	67,126

The table shows a fall corresponding with that of consumption down to 1910 and then a rise preceding the war; thereafter a rapid fall down to 1918, with a subsequent rise in 1919–20, followed by a pretty level rate, with a sharp fall for the year 1926, which was signalized by the general strike and the seven months' mining struggle The general correspondence between the police figures and the statistics of consumption proves the trustworthiness of the former, which is further confirmed by the medical records:

England and Wales Drunkenness and Medical Results

Year	Convictions for drunkenness		Deaths from alcoholism		Deaths from cirrhosis of the liver	
	M	F	M.	F.	M.	F
1913	153,112	35,765	1,288	865	2,088	1,586
1914	146,517	37,311	1,310	881	2,253	1,620
1915	102,600	33,211	1,027	745	1,994	1,421
1916	62,946	21,245	753	447	1,736	1,096
1917	34,103	12,307	446	292	1,423	775
1918	21,853	7,222	280	108	1,063	575
1919	46,765	11,183	354	112	900	510
1920	80,517	15,246	546	173	1,085	550
1921	64,897	12,892	454	193	1,188	585
1922	63,253	13,094	438	183	1,168	588
1923	63,850	13,244	376	186	1,071	551
1924	66,139	12,043	384	158	1,036	573
1945	62,843	12,224	331	177	1,114	597
1926	55,836	11,290	315	184	1,131	601

State Control.—Other points in war experiments remain to be considered in view of temperance activities One of these is State control It was adopted in South Carolina in 1893 and was inaugurated for Russia in 1895. It was brought to the front in Great Britain by the war experience. Among the powers conferred on the Liquor Control Board were those of purchasing and carrying on the trade, which meant State purchase The Board made use of these powers to a very limited extent, directly connected with the war In 1926 it took over the trade in four areas —Cromarty and Invergordon—at the instance of the Admiralty, Enfield at that of the Ministry of Munitions, Carlisle and the adjoining district of Gretna because of an enormous factory erected for munitions The Carlisle and Gretna area is the only one of permanent importance It was placed under the usual restrictions in Nov 1915, but they failed to prevent an immense increase of drunkenness due to the presence of 22,000 navvies, engaged on construction work (the figures were given by the resident engineer). The board felt impelled to take drastic action and began the process, in Jan. 1916, by purchasing public-houses in the villages. Its operations were gradually extended until they embraced an area of about 500 sq m. with a population of 140,000, in which Carlisle (52,000) was the only considerable town. The changes introduced into the liquor trade included. (1) Its concentration, (2) reduction in the number of licensed houses, (3) their re-arrangement and improvement, (4) the provision of meals, (5) salaried managers, (6) minor changes including the abolition of "grocers' licences." All these were very thoroughly carried out in the years following. In Carlisle itself only two establishments, a hotel and a restaurant, remain outside the State scheme, which has been carried on by the Home Office, after the dispersal of the Control Board in 1921.

The competition of clubs has been mentioned above. By the act of 1921 the hours of sale are the same as for the public-house, and registration has been compulsory since 1903, which involves power to strike a club off the roll for misconduct. But clubs are in a privileged position, and since the war they have increased steadily and rapidly from 7,972 in 1918 to 12,480 in

1927, while public-houses have become fewer, as already shown. A large number of the clubs are political, and there is a strong agitation for freeing them from all restrictions; while, on the other hand, the unfair competition with the public-house is insisted on.

The Temperance (Scotland) Act has no connection with the World War; it was passed in 1913, but did not come into operation until 1920. It is a local option act, which gives constituencies the power: (1) To remain as they are, (2) to vote for limitation of licences, (3) to vote for no licence.

The Drink Bill.—The following figures, which give an estimate of the national expenditure in Great Britain on drink, have been supplied by the courtesy of the United Kingdom Alliance:

Great Britain

Year	*Expenditure*	*Per head of population*	*Taxation*
	£	£	£
1900	168,500,000	4–10–4½	36,800,000
1913	153,500,000	3–12–5	34,800,000
1920	453,000,000	10–0–0	181,000,000
1927	298,000,000	6–15–3	128,500,000

The great rise shown in 1920 and 1927 over the previous figures is due to the high prices of drink caused mainly by taxation, though it is to be noted that, in 1927, the nation spent on drink alone, quite apart from tax, nearly £40,000,000 more than in 1900.

World Changes.—In 1927 a Licensing Act was passed by the Irish Free State following a commission of enquiry. The principal measure was a reduction of the hours of sale; but the great change effected since the war is nation-wide Prohibition in the United States. It is separately dealt with (*see* PROHIBITION), and therefore little will be said about it here. It was not due to the war, as for many years past individual States have been adopting Prohibition; but the war gave a stimulus to the movement, which in 1919 reached the point required for an amendment to the Constitution. This step has given rise to an immense and interminable controversy, in which opinions of great weight can be quoted on both sides; but its effect outside the United States has been rather to check the movement for Prohibition, which was at first stimulated by the action of the United States. What follows is taken from the *International Record* and other sources.

Austria. A great campaign for reform of the liquor laws is being carried on. The proposals include: (1) Prohibition of sale from noon on Saturday to Monday morning; (2) prohibition of sale to persons under 18; (3) gradual extinction of licences; (4) debts for drink to be irrecoverable; (5) local option.

Belgium. By a law promoted by M. Vandervelde the retail sale of spirits for consumption on the premises is prohibited, but consumption has increased.

Bulgaria. The director of health has proposed a bill providing for (1) Local option; (2) the limitation of licences in proportion to population; (3) other restrictions of locality; (4) hours of sale to be from 8 A.M. to mid-day and from 2 to 6 P.M. with closing on Sundays and holidays; (5) prohibition of sale to persons under 20, sick people, students and police.

Czechoslovakia. An active campaign is being carried on under the presidency of Prof. Fourtka. Temperance teaching in schools is encouraged by the Government.

Denmark. The Temperance Commission appointed in 1914 has issued a final report. The majority of nine members think that education will suffice; the minority of six propose that the people shall have power locally to veto the granting of new licences and nationally to suppress liquor containing more than 2¼% of alcohol.

Finland. Finland is the one Prohibition country on the Continent. It was adopted there in 1916. Drunkenness is said to be excessive and a recent unofficial plebiscite declared against Prohibition, but its repeal is unlikely.

France. The temperance movement is directed mainly against spirits; the minister of commerce recently prohibited publicity concerning wines and spirits in post offices and on all administrative documents.

Germany. A strong movement in favour of local option is in progress.

Holland. The minister of labour has introduced a licensing bill, providing for local option.

Hungary. The licensing laws have been amended by a provision prohibiting the sale of drink to persons under 18.

Iceland. Iceland has Prohibition, and has experienced the difficulty of enforcement. Recently the Government has appointed supervisors with a view to enforcing the law more effectually.

Italy. The most interesting movement in Italy is one favoured by the Government for manufacturing non-alcoholic drinks from grapes and other fruits. The Ministry of Labour has forbidden the use of all kinds of alcoholic drinks in factories.

Norway. In 1927 Norway, by popular vote, gave up Prohibition of spirits in favour of local option.

Poland. The temperance organizations are active and made their first entrance into the electoral field at the last general election by urging electors to vote only for candidates in favour of reform legislation.

Rumania. The Government has in hand a bill for "progressive prohibition," whereby licenced houses will be reduced and gradually closed until in 12 years' time there will be none.

Russia. In Russia, where the Government monopoly of the manufacture and sale of vodka, which ceased in the war, has been restored, complaints of drunkenness and illicit distillation are rife; but the Government is too dependent on the revenue from vodka to give it up.

Sweden. During the war spirits were severely rationed, with the result of encouraging illicit distillation. After the war the country returned to the system of disinterested management, known as the Gothenburg system, as modified by Dr. Bratt.

Switzerland. There appears to be a conflict between the Federal Council and the temperance organizations. The former has introduced a bill in the national parliament, giving peasants the right to distil their own fruit, but providing that any excess, not required for domestic use, should be handed over to the liquor monopoly. This is opposed by the temperance societies.

Turkey. Prohibition was abandoned by Turkey in 1924, in favour of a Government monopoly.

Australia. The Prohibition movement is strong, but the wine business, which has become extensive and lucrative, is against it. The States have their own liquor systems, decided by popular vote; but no State has yet voted for Prohibition. Queensland voted in 1922 for continuance of licences. New South Wales has had no poll. Victoria will poll in 1930, West Australia voted against Prohibition in 1925.

New Zealand. New Zealand adopted local option in 1893 and 12 electorates secured no licence.

Canada. The greatest reaction against Prohibition is shown by Canada, which has repealed it in one province after another, except Nova Scotia, mostly in favour of Government control, though in some provision is made for local option. Newfoundland, after trying Prohibition for five years, has given it up for Government sale.

Science and Alcohol.—In 1916 the Liquor Control Board appointed a scientific advisory committee, which reported in 1918 and furnished a "review of the existing state of scientific knowledge regarding the action of alcohol on the human organism" as a "provisional basis for further research." This review was valuable, because it put together in a systematic way a large number of observations occurring only in various scientific journals. The committee continued the further research, with the addition of two members, and in 1920 prepared a revised version, which was not, however, published. In 1921 on the dissolution of the Control Board the Medical Research Council were invited by the home secretary to re-appoint the committee as one of their own investigation committee, and so to preserve the continuity of the work. They did so, and in 1924 published a revised version of their report, together with the two prefaces written in 1917 and 1920 by Lord D'Abernon, chairman of the Control Board and of the advisory committee.

TEMPERATURE OF BODY: *see* ANIMAL HEAT

TEMPERING is the imparting of a certain degree of hardness to a tool or spring The older practice was that of first hardening a tool to the limit, and then "letting it down," *e g*, allowing access of heat until a certain colour was shown on a part polished bright for observation, and then quenching in water or oil This method is still practised on a large scale, but with the use of furnaces and pyrometers the tempering heat can be raised accurately without going through the hardening process first. Tempering colours range from the bright yellow down to grey, covering such tints as pure yellow, dark yellow, brown yellow, red brown, purple red, violet, cornflower blue, pale blue. The bright yellow gives the hardest temper suitable for steel engraving tools and certain metal cutting tools, while at the other end of the range lie saws for wood and most springs. *See* also ANNEALING and HARDENING

TEMPLARS. The Knights Templars, or Poor Knights of Christ and of the Temple of Solomon (*pauperes commilitones Christi templique Salomonici*), formed one of the three great military orders, founded in the 12th century Unlike the Hospitallers and the Teutonic Knights it was a military order from its very origin. Its founders were a Burgundian knight named Hugues de Payns and Godeffroi de St Omer, a knight from northern France, who in 1119 undertook the pious task of protecting the pilgrims who, after the first crusade, flocked to Jerusalem and the other sacred spots in the Holy Land They were quickly joined by six other knights and soon afterwards organized themselves as a religious community, taking an oath to the patriarch of Jerusalem to guard the public roads, to forsake worldly chivalry, "of which human favour and not Jesus Christ was the cause," and, living in chastity, obedience and poverty, according to the rule of St Benedict, "to fight with a pure mind for the supreme and true King"

To this nascent order of warrior monks Baldwin I., king of Jerusalem, handed over a part of his royal palace lying next to the former mosque of al-Aksa, the so-called "Temple of Solomon," whence they took their name They had at first no distinctive habit, wearing any old clothes that might be given to them Nor was their community exclusive Their primitive rule seems to have enjoined them especially to seek out excommunicated knights, and to admit them, after absolution by the bishop, to their order, and they thus served a useful purpose in at once disciplining and converting the unruly rabble of "rogues and impious men, robbers and committers of sacrilege, murderers, perjurers and adulterers"[1] who streamed to the Holy Land in hope of plunder and salvation It was this rule which led later to the most important privilege of the order, the immunity from sentences of excommunication pronounced by bishops and parish priests.

This practice might have brought them at once under the suspicion of the Church, and it soon became expedient to obtain the highest sanction for the new order and its rules. In the autumn of 1127 accordingly Hugues de Payns, with certain companions, appeared in Europe, where he was fortunate enough to secure the enthusiastic support of the all-powerful abbot of Clairvaux Grateful pilgrims had already begun to enrich the order; the *De laude novae militiae*, a glowing panegyric of this new and holy conception of knighthood, addressed by Bernard to Hugues de Payns by name, insured the success of his mission. In 1128 the council of Troyes discussed and sanctioned the rule of the order.

Rule of the Temple.—No ms. of the original French Rule of the Temple (*Règle du Temple*) exists, but in essentials the later copies preserve the matter and spirit of the primitive Rule, and they prove that to the end the order was, in principle at least, submitted to the same strict discipline as at the beginning Of a secret Rule, in spite of the most diligent research, no trace has ever been found It is now generally held that none ever existed The legend of its existence, so fatal to the order, is probably traceable to the fact that the complete Rule was jealously guarded by the chief office-bearers of the order.

The *Règle du Temple* in its final form as we now possess it contains the rules for the constitution and administration of the order; the duties and privileges of the various classes of its personnel; the monastic rules, regulations as to costume and as to religious services; rules for the holding of chapters, and a summary of offences and their punishment; the procedure at the election of a grand master and at receptions into the order; a definition of the relations of the order to the pope, and to other religious orders

At the head of the order was the master of the Temple at Jerusalem (in Cyprus after the fall of the Latin Kingdom), known as the grand master. His authority was very great—except in certain reserved cases his word was law—but he was not absolute Thus in matters of special importance—alienation of the estates of the order, attack on a fortress, declaration of war, conclusion of an armistice, reception of a new brother—he had to consult the chapter, and was bound by the vote of the majority; nor could he modify or abrogate a decree of the council of the order without their consent He had to obtain the consent of the chapter also to the nomination of the grand commanders of the provinces of the order; the lesser offices were absolutely in his gift. He was elected by a complicated process, a chapter summoned *ad hoc* electing a "commander of the election" and one other brother who, after vigil and prayer, co-opted two more, these four choosing another two, and so on till the number of the twelve apostles had been reached A chaplain, representing Jesus Christ, was then added to complete the electoral college. (*See* Curzon, *Règle du Temple*, p xxxv)

Of peculiar importance were the *chaplains* (*fratres capellani*) These did not originally form part of the order, which was served by priests from outside The bull *Omne datum optimum* of 1163 imposed on clerics attaching themselves to the order an oath of life-long obedience to the grand master; by the middle of the 13th century the chaplains took the same oath as the other brothers and were distinguished from them only by their orders and the privileges these implied (*e g.*, they were spared the more humiliating punishments, shaved the face, and had a separate cup to drink out of) The order thus had its own clergy, exempt from the jurisdiction of diocesan bishops and parish priests, owing obedience to the grand master and the pope alone.

It remains to be said that the brethren were admitted either for life or for a term of years. Married men were also received, but on condition of bequeathing one half of their property to the order.

History.—Long before St. Bernard's death (1153) the new order was established in almost every kingdom of Latin Christendom, and every establishment was the recipient of rich endowments. Henry I, for example, granted them lands in Normandy; and Louis VII. in the latter years of his reign gave them a

[1]Bernard of Clairvaux, *De laude novae militiae*, cap v (in Migne, *Patrol. lat.* 182, p 928).

piece of land outside Paris, which in later times became known as the Temple, and was the headquarters of the order in Europe, and Stephen of England granted them the manors of Cressing and Witham* in Essex, and his wife Matilda that of Cowley, near Oxford. Spiritual privileges were granted to them by the popes as lavishly as temporal possessions by the princes and people. Pope Adrian IV. allowed them to have their own churches; Eugenius III. added to these the right to have churchyards. They were, moreover, as defenders of the Church exempted from the payment of tithes. Finally, they were exempted from the action even of general censures and decrees of the popes, unless mentioned in them by name. Very soon the order refused to submit in any way to the ordinary jurisdiction of the diocesan bishops and formed in effect a separate ecclesiastical organization under the pope as supreme bishop. The result was that, scarce twenty-five years after its foundation, the order was at open feud with bishops and parish priests, and the popes found it necessary to issue decree after decree to protect it from violence and spoliation.

So long, however, as the attention of the papacy and of Christendom was fixed on the problem of recovering and safeguarding the Holy Land, the position of the Templars was unassailable and all efforts to curb the growth of their power vain. The later history of the Templars is therefore the history of the CRUSADES (*q.v.*).

Fall of Latin Kingdom.—There is something Homeric in the story of the fall of the Latin kingdom as related by the historians of the next century. A French knight, Gerard de Riderfort, coming to the East in quest of fortune, attached himself to the service of the ambitious Raymond, count of Tripoli; looking for the hand of some wealthy widow in reward. Failing ignominiously in this, Gerard enrolled himself among the Templars, biding his time for revenge, and was elected grand master in 1184. Baldwin IV., king of Jerusalem, died in 1185, leaving the throne to his young nephew Baldwin V., the son of his sister Sibylla, under the guardianship of Raymond, whose term of office was brief, as the little king died in September 1186. This was Gerard's opportunity. The Templars carried the body of their dead sovereign to Jerusalem for burial; and then, unknown to the barons of the realm, Gerard and the patriarch crowned Sibylla and her husband Guy de Lusignan, Raymond's rival. This was the overthrow of Raymond's ambition; and both Latin and Arabic writers are agreed that the Christian count and the Mohammedan sultan now entered into an alliance. To break this friendship and so save the kingdom, Gerard and the grand master of the Hospitallers were sent north to make terms with Raymond. But the rash valour of the Templars provoked a hopeless contest with 7,000 Saracens. The grand master of the Hospitallers was slain; but Gerard made his escape with three knights to Nazareth (1st May 1187). In this emergency Raymond became reconciled with Guy; and Gerard placed the Temple treasures of Henry II. at his king's disposal. Once more it was the Templars' rashness that led to the disastrous battle of Hittin (4th July). Gerard and the king fell into the hands of Saladin, but were released about a year later; Raymond of Tripoli made his escape through treachery or fortune; and 230 Templars fell in or after the battle, for the fight was scarcely over before Saladin ordered all the Templars and Hospitallers to be murdered in cold blood. One after another the Christian fortresses of Palestine fell into the hands of Saladin. Jerusalem surrendered on 2nd–3rd October 1187, and the treasures of the Temple coffers were used to purchase the redemption of the poorer Christians, part of whom the Templar warriors guarded on their sad march from the Holy City to Tripoli. Part of their wealth was expended by Conrad of Montferrat in the defence of Tyre; but, when this prince refused to admit Guy to his city, both the Templars and the Hospitallers from the neighbouring parts flocked to the banner of their released king and accompanied him to the siege of Acre (22nd August 1189). In his company they bore their part in the two years' siege and the terrible famine of 1190–91; and their grand master died in the great battle of 4th October 1189, refusing to survive the slaughter of his brethren.

On the capture of Acre Philip Augustus established himself in the palace of the Templars, who are, however, stated to have sympathized with Richard. The English king sold them the island of Cyprus for 100,000 besants; but, unable to pay the purchase money, they transferred the debt and the principality to Guy of Lusignan. Richard consulted them before deciding on any great military movement; and in June 1192 they advocated the bold plan of an advance on Egypt rather than on Jerusalem. It was in the disguise of a Templar and in a Templar galley that Richard left the Holy Land, after the failure of his own military schemes. When Acre was recovered, the Templars, like the Hospitallers, received their own quarters in the town, which from this time became the centre of the order. On the death of Henry of Champagne (1197) they vetoed the election of Raoul de Tabarie; after the death of his successor Amalric they refused to renew the truce with Saladin's brother, Saif al-Dīn, and led an expedition against the Saracens before the arrival of the new king, John de Brienne, at whose coronation in 1210 William de Chartres, the grand master, was present. Seven years later, with the aid of Walter de Avennis and of the Teutonic Knights, they commenced the building of their fortress of Castle Pilgrim, near Acre, on a rocky promontory washed by the Mediterranean on every side except the east.

It was from this castle that in May 1218 the fifth crusade started for the expedition against Egypt. The Templars were the heroes of the siege of Damietta, at which William de Chartres was slain. "First to attack and last to retreat," they saved the Christian army from annihilation on 29th August 1219; and when the city surrendered (5th November) the only one of its twenty-eight towers that had begun to give way had been shaken by their engines. On the other hand, it was largely owing to their objections that John de Brienne refused the sultan's offer to restore Jerusalem and Palestine.

From the very first the Templars seem to have been opposed to Frederick II., and when he landed at Acre (7th September 1228) they refused to march under the banners of an excommunicated man, and would only accompany his host from Acre to Joppa in a separate body. They were accused of notifying Frederick's intended pilgrimage to the Jordan to the sultan, and they were certainly opposed to Frederick's ten years' peace with Al-Kāmil, the sultan of Egypt, and refused to be present at his coronation in Jerusalem. On neither side was the treaty fully observed; and preparations were made in Europe for a fresh crusade. In the meantime open dissension broke out between the Templars and the Hospitallers, the former advocating negotiations with the sultans of Damascus and Kerak, the latter with the sultan of Egypt; and when Richard of Cornwall arrived (11th October) he had to decide between the two rival orders and their opposing policies. After some hesitation he concluded a treaty with the sultan of Egypt, much to the annoyance of the Templars, who openly mocked his efforts. On his departure the three orders came to open discord: the Templars laid siege to the Hospitallers in Acre and drove out the Teutonic Knights "in contumeliam imperatoris." They were successful on all sides. The negotiations with Damascus and Kerak were reopened, and in 1244 Hermann of Perigord wrote to the princes of Europe that after a "silence of fifty-six years the divine mysteries would once more be celebrated in the Holy City."

It was in this moment of danger that the sultan of Babylon called in the barbarous Kharizmians, whom the Mongol invasions had driven from their native lands. These savages, entering from the north, flowed like a tide past the newly built and impregnable Templar fortress of Safed, swept down on Jerusalem, and annihilated the Christian army near Gaza on October 18th, 1244. From this blow the Latin kingdom of the East never recovered; 600 knights took part in the battle; the whole force of the Templars, 300 in number, was present, but only 18 survived, and of 200 Hospitallers only 16. The masters of both orders were slain or taken prisoners, and Jerusalem was lost to Christendom once more. The havoc caused by the Kharizmians was alleged by pope Innocent IV. as the reason for again summoning Christendom to the rescue of the Holy Land. Recognizing the fact that the true

way to Jerusalem lay through Egypt, Louis IX. led his host to the banks of the Nile, being accompanied by the Templars. Their master, William de Sonnac, attempted in vain to restrain the rash advance of the count of Artois at the battle of Mansura (8th February 1250), which only three Templars survived. St. Louis, when captured a few weeks later, owed his speedy release to the generosity with which the order advanced his ransom-money

A new enemy was now threatening Mohammedan and Christian alike For a time the Mongol advance may have been welcomed by the Christian cities, as one after another the Mohammedan principalities of the north fell before the new invaders. But this new danger stimulated the energies of Egypt, which under the Mameluke Bibars encroached year after year on the scanty remains of the Latin kingdom. The great Frankish lords, fearing that all was lost, made haste to sell their lands to the Templars and Hospitallers before quitting Palestine for ever But they lost their power of resistance, and became so enfeebled as to welcome the treaty which secured them the plain of Acre and a free road to Nazareth as the result of the English crusade of 1272. While thus weak against external foes, the Templars were strong enough for internal warfare. In 1277 they espoused the quarrel of the bishop of Tripoli, formerly a member of the order, against his nephew Bohemond, prince of Antioch and Tripoli, and began a war which lasted three years. In 1276 their conduct drove Hugh III., king of Cyprus and Jerusalem, from Acre to Tyre. In the ensuing year, when Mary of Antioch had sold her claim to the crown to Charles of Anjou, they welcomed this prince's lieutenant to Acre and succeeded for the moment in forcing the knights of that city to do homage to the new king Thirteen years later (26th April 1290) Tripoli fell, and next year Acre, after a siege of six weeks, at the close of which (16th May) William de Beaujeu, the grand master, was slain The few surviving Templars elected a new master, and sailed for Cyprus, which now became the headquarters of the order.

Power and Influence of the Order.—For more than a hundred years the Templars had been one of the wealthiest and most influential factors in European politics. If we confine our attention to the East, we realize but a small part of their enormous power. Two Templars were appointed guardians of the disputed castles on the betrothal of Prince Henry of England and the French princess in 1161. Other Templars were almoners of Henry III. of England and of Philip IV. of France. One grand master was godfather to a daughter of Louis IX , another, despite the prohibition of the order, is said to have been godfather to a child of Philip IV They were summoned to the great councils of the Church, such as the Lateran of 1215 and the Lyons council of 1274 Frederick II 's persecution of their order was one of the main causes of his excommunication in 1239; and his last will enjoined the restoration of their estates. Their property was scattered over every country of Christendom, from Denmark to Spain, from Ireland to Cyprus. But the wealth of the Templars was due not so much to their territorial possessions as to the fact that they were the great international financiers and bankers of the age. The Paris Temple was the centre of the world's money market. In it popes and kings deposited their revenues, and these vast sums were not hoarded but issued as loans on adequate security. Above all, it was the Templars who made the exchange of money with the East possible. It is easy, indeed, to see how they were the ideal bankers of the age; their strongholds were scattered from Armenia to Ireland, their military power and strict discipline ensured the safe transmission of treasure, while their reputation as monks guaranteed their integrity Thus they became the predecessors, and later the rivals, of the great Italian banking companies. To take interest (usury) was of course unlawful The method of circumventing this seems to have been that the mortgagees paid to the mortgagors a *nominal* rent which was used towards the reduction of the debt. The difference between this and the *real* rent represented the interest. A document throwing a vivid light on the banking methods of the Templars and Hospitallers is a charter of Margaret, queen of the English, A.D. 1186, from the abbey of Fontevrault, printed in *Calendar of Documents*, France (1899), vol. i., ed J. H. Round, No. 1084.

Suppression of the Order.—Never had the order of the Temple been to all appearance more powerful than immediately before its ruin. Sovereign power, in the sense of that of the Teutonic Knights in Prussia or the Knights of St. John in Rhodes and later in Malta, it had never possessed; but its privileges and immunities constituted it a church within the church and—in France at least—a state within the state. Philip IV, indeed, in pursuance of his policy of centralizing power in the crown, had from 1287 onwards made tentative efforts to curtail the power and wealth of the order; but soon his necessities forced him to a temporary change of policy. In January 1293 the privileges of the order in and about Paris were confirmed and extended, and in 1297 Philip borrowed 5,200 *livres tournoises* from the Paris Temple. Then came the great quarrel with Pope Boniface VIII, and on the 10th of August 1303 the king signed with Hugues de Peraud, the general visitor of the French Templars, a formal treaty of alliance against the pope. On the 6th of February 1304 Boniface's successor, Benedict XI., once more confirmed all the Templars' privileges; while Philip, for his part, appointed Hugues de Peraud receiver of the royal revenues and, under pressure of the disastrous campaign in Flanders, in June granted a charter exempting the order from all hindrances to the acquisition of property Two years later the king took refuge in the Temple from the violence of the Paris mob, and so late as the spring of 1307 was present at the reception of a new Templar.

Yet for some two years past the king had been plotting a treacherous attack on the order His motives are clear: he had used every expedient to raise money, had robbed and expelled the Jews and the Lombard bankers, had debased the coinage, the suppression of the Templars would at once rescue him from their unwelcome tutelage and replenish his coffers He cherished also another ambition The question of an amalgamation of the great military orders had often been mooted, the project had been approved by successive popes in the interests of the Holy Land, it had been formally proposed at the Lyons council of 1274, only to be rejected by the opposition of the Templars and Hospitallers themselves. To Philip this scheme commended itself as an opportunity for bringing the orders under the control of the French crown, there was to be but one order, that of the "Knights of Jerusalem," of which the grand master was always to be a prince of the royal house of France. Clearly, it only needed an excuse and a favourable opportunity to make him attack the Templars, and, once having attacked them, nothing short of their entire destruction would have been consistent with his safety. The excuse was found in the denunciation of the order for heresy and unspeakable immoralities by a venal informer; the opportunity was the election of a pope, Clement V, wholly devoted to the interests of the king of France.

For perhaps half a century there had been strange stories circulating as to the secret rites practised by the order at its midnight meetings, stories which probably had their origin in the extreme precautions taken by the Templars, originally perhaps for military reasons, to secure the secrecy of their proceedings, which excited popular curiosity and suspicion.

In the spring of 1304 or 1305 a certain Esquiu de Floyran of Béziers pretended to betray the "secret of the Templars" to James II of Aragon. The pious king, who had every reason to think well of the order, did not affect to be convinced; but the prospect of spoils was alluring, and he seems to have promised the informer a share of the booty if he could make good his charges Esquiu now turned to Philip of France, with more immediate success. For the purpose of collecting additional evidence the king caused twelve spies to find admission to the order, and in the meantime sought to win over the pope to his views. Clement V. owed the tiara to the diplomacy of Philip's agents, perhaps to their gold; but though a weak man, and moreover a martyr to ill health, he was not so immediately accommodating as the king might have wished, expressing his disbelief in the charges against the order, and, though promising an inquiry, doing his best to procrastinate Philip determined to force his hand. All France

was at this time under the jurisdiction of the Inquisition, and the Inquisition could act without consulting the pope. The grand inquisitor of France, William of Paris, was Philip's confessor and creature. The way was thus open for the king to carry out his plan by a perfectly legal method. His informers denounced the Templars to the Inquisition, and the grand inquisitor—as was the customary procedure in the case of persons accused of heresy—demanded their arrest by the civil power. On the 14th of September 1307, accordingly, Philip issued writs to his *baillis* and seneschals throughout the kingdom, directing them to make preparations to arrest the members of the order.

The Templars had for some time past been aware of the charges against them. On the 6th of June 1306 Pope Clement had summoned Jacques de Molay, the grand master, from Cyprus to France, in order to consult him on the projected crusade. He had obeyed the call, and, in an interview with the pope, had taken the opportunity to demand a full inquiry. They had, however, taken no measures to defend themselves; the sudden action of the king took them wholly by surprise; and on the night of Friday, the 13th of October 1307, their arrest was effected without difficulty, Jacques de Molay himself with sixty of his brethren being seized in Paris.

The Templars were caught in toils from which there was no escape. To force them to confess, they were first tortured by the royal officials, before being handed over to the inquisitors to be, if need were, tortured again. In Paris alone thirty-six died under the process. The result was, at the outset, all that the king could desire. Of 138 Templars examined in Paris between the 19th of October and 24th of November, some of them old men who had been in the order the greater part of their lives, 123 confessed to spitting on (or "near") the crucifix at their reception. Many of the prisoners confessed to all the charges, however grotesque. But the most damning confession was that of the grand master himself, publicly made with tears and protestations of contrition and embodied in a letter (October 25) sent to all the Templars in France. He had been guilty, he said, of denying Christ and spitting on the cross.

To the pope, meanwhile, the proceedings in France were to the highest degree unwelcome. He had, indeed, become convinced, if not of the general guilt of the order, at least of the guilt of some of its members. But the affair was one which he desired to reserve for his own judgment; Philip's action he interpreted, rightly, as an encroachment of the civil power on the privileges and property of the Church, and his fears were increased when the French king, without consulting him, sent letters to King James of Aragon, Edward II. of England, the German king Albert and other princes, calling upon them to imitate his example. On the 27th of October Clement issued letters suspending the powers of the Inquisition in France. What followed is not clear, for the documentary evidence for these months is very defective; but on the 22nd of November the pope issued a bull calling on all kings and princes to arrest the Templars everywhere, his motive probably being to forestall the probable action of the secular powers and keep the affair in his own hands. All scruples and hesitations now vanished. In England the Templars were arrested on the 10th of January 1308, in Sicily on the 24th of the same month, in Cyprus on the 27th of May; in Aragon and Castile the process was less easy, for the knights, forewarned, had put their fortresses into a state of defence, notably their strong castle of Monzon, which was only taken after a long siege on the 17th of May, while the last of the Templars' strongholds, Castellat, did not fall until Nov. 2nd.

Meanwhile, on the 26th of May, Philip had made his solemn entry into Poitiers, where the pope and cardinals had already assembled for the purpose of conferring with the king on the matter. After stormy debate, an arrangement was made. The king agreed to hand over to the papal commissioners the property and persons of the Templars; Clement, for his part, withdrew the sentence of suspension against the grand inquisitor of France and ordered an inquisition into the charges against individual Templars by the diocesan bishops with assessors nominated by himself. The examination of the grand master, of the grand visitor of France, and of the grand preceptors of Cyprus, Normandy and Aquitaine he reserved to himself. Inquisition was to be made into the conduct of the order in each country by special papal commissions; and the fate of the order as a whole was to be decided by a general council, summoned at Vienne for the 1st of October 1311, when the question of the guilt of the order might be considered. Meanwhile the pope and cardinals had elaborated the organization of the new inquisition. There was much confusion and delay, however, and the actual public trial did not begin till the 11th of April, 1310. Many Templars, trusting in the assurance implied in their citation, had volunteered to defend the order and withdrew their previous confessions. They were soon undeceived; the commission was packed with creatures of the crown. The evidence given in Paris for or against the order was, it was soon found, used against the individual Templars on their return to the provinces; the retractation of a confession, under the rules set up for the diocesan inquisition, was punished with death by fire. Sixty-seven Templars perished in this way during May 1310. Meanwhile Clement and Philip had come to terms. The pope condemned the Templars. The council of Vienne met in October 1311. A discussion arose as to whether the Templars should be heard in their own defence. Clement, it is said, broke up the session to avoid compliance; and when seven Templars offered themselves as deputies for the defence he had them cast into prison. Towards the beginning of March Philip came to Vienne, and he was seated at the pope's right hand when that pontiff delivered his sermon against the Templars (3rd April 1312), whose order had just been abolished, not at the general council, but in private consistory (22nd March). On 2nd May 1312 he published the bull *Ad Providam*, transferring the goods of the society, except for the kingdoms of Castile, Aragon, Portugal and Majorca, to the Knights of St. John.

The final act of the stupendous tragedy came early in 1314. Jacques de Molay, the grand master, had not hitherto risen to the height of his great position; the fear of torture alone had been enough to make him confess, and this confession had been used to extract avowals from his brethren, subject as they were to unspeakable sufferings and accustomed to yield to the military chief. Humiliation on humiliation had been heaped on the wretched man, public recantations, reiterated confessions. Before the papal commission he had flamed into anger, protested, equivocated—only in the end to repeat his confession once more. The same had happened before the commission of cardinals at Chinon; the audience with the pope, which he demanded, he had never obtained. On the 6th of May 1312 Pope Clement issued his final decision as to the fate of the Templars in general; that of the five great offices of the order he reserved in his own hand. With this a silence falls over the history of the Templars; the fate of the order had been decided, that of the individuals still under trial was of little interest to contemporary chroniclers. Then the veil is suddenly lifted. Jacques de Molay has found his wonted courage at last, and with him Gaufrid de Charney, the preceptor of Normandy; on the 14th of March 1314 they were brought out on to a scaffold erected in front of Notre Dame, there in the presence of the papal legates and of the people to repeat their confessions and to receive their sentence of perpetual imprisonment. Instead, they seized the opportunity to withdraw their confessions and to protest to the assembled thousands the innocence of the order. King Philip the Fair did not wait to consult the Church as to what he should do; he had them burnt.

A word must be added as to the significance of the work of the Templars and of the manner of their fall in the history of the world. Two great things the order had done for European civilization: in the East and in Spain it had successfully checked the advance of Islam; it had deepened and given a religious sanction to the idea of the chivalrous man, the *homo legalis*, and so opened up, to a class of people who for centuries to come were to exercise enormous influence, spheres of activity the beneficent effects of which are still recognizable in the world. On the other hand, the destruction of the Templars had three consequences fateful for Christian civilization. (1) It facilitated the conquests of the Turks by preventing the Templars from playing in Cyprus

the part which the Knights of St. John played in Malta. (2) It partly set a precedent for, partly confirmed, the cruel criminal procedure of France, which lasted to the Revolution. (3) It set the seal of the highest authority on the popular belief in witchcraft and personal intercourse with the devil, sanctioned the expedient of wringing confessions of such intercourse from the accused by unspeakable tortures, and so made possible the hideous witch-persecutions which darkened the later middle ages and, even in Protestant countries, long survived the period of Reformation.

On the question of the guilt or innocence of the Templars in respect of the specific charges on which the order was condemned opinion has long been divided. Their innocence was maintained by the greatest of all their contemporaries, Dante (Purg. xx. 92), and by the historian Villani and others. In more recent times a certain heat was introduced into the discussion of the question owing to its having been for centuries brought into the arena of party controversy, between Protestants and Catholics, Gallicans and Ultramontanes, Freemasons and the Church. Thus in 1654 Pierre Du Puy, librarian of the Bibliothèque Royale, published his work on the Templars to confute those who sought to establish their innocence in order to discredit a king of France. On the other hand, Nicolas Gurtler published his *Historia Templariorum* (Amsterdam, 1691, 2nd ed. 1703) to show, as a good Protestant, that the Templars had the usual vices of Roman Catholics, while, according to Loiseleur, the later editors of Du Puy were Freemasons who, under false names, garbled the old material and inserted new in the interests of the supposed origin of their own order in that of the Templars Several Roman Catholic champions of the order now entered the field, notably the Premonstratensian canon R. P. M. Jeune, prior of Etival, who in 1789 published at Paris his *Histoire critique et apologétique de l'ordre des chevaliers . . . dits Templiers,* a valuable work directed specifically against Gurtler and Du Puy. In the 19th century a fresh impetus was given to the discussion by the publication in 1813 of Raynouard's brilliant defence of the order. The challenge was taken up, among others, by the orientalist F von Hammer-Purgstall who, in a paper entitled "Mysterium Baphometis" (*Fundgraben des Orients,* vol. vi, Vienna 1818), attempted to prove that the Templars followed the doctrines and rites of the Gnostic "Ophites" (*q v.*), and gave reproductions of obscene representations of supposed Gnostic ceremonies and of mystic symbols said to have been found in Templars' buildings. W. F. Wilcke (*Geschichte des Tempelherrenordens,* 1826, 2nd ed 1860), while rejecting Hammer's main conclusions as unproved, argued for the existence of a secret doctrine based not on Gnosticism but on the monotheism of Islam, of which Baphomet (Mahomet) was a symbol. On the other hand, Wilhelm Havermann (*Geschichte des Ausganges des Tempelherrenordens,* 1846) decided in favour of the innocence of the order. This view was also taken by a succession of German scholars, in England, by C. G. Addison; and in France by a whole series of conspicuous writers Mignet, Guizot, Renan, and others. On the other hand, Hans Prutz, in a series of brilliant contributions, of which the most well-considered is his *Entwicklung und Untergang des Tempelherrenordens* (1888), maintained that the custom of denying Christ and spitting on the cross was often, and in some provinces universally, practised at the reception of the brethren, "as a coarse test of obedience, of which the original sense had partly been forgotten, partly heretically interpreted under the influence of later heresies" Prutz points out that the failure of the Crusades had weakened men's absolute belief in Christianity, at least as represented by the mediaeval Church (*Kulturgeschichte der Kreuzzuge,* p. 268 ff.)

H. C. Lea, in his *History of the Inquisition* (1888, vol. iii), had already come independently to the conclusion that the Templars were innocent. Lastly appeared the fascinatingly interesting and closely reasoned book of Professor H Finke (1907) which, based partly on a mass of new material drawn from the Aragonese archives, had for its object to establish the innocence of the order on an incontrovertible basis (*Papsthum und Untergang des Templenordens,* 1907)

Bibliography.—The original sources given by Du Puy, though often valuable, were selected and edited with a purpose; but Michelet's *Procès des Templiers* (2 vols, 1851, 1861), gives the original minutes of the trial preserved at the Bibliothèque Nationale. This is analysed by Gmelin (*op. cit*). Of documents published elsewhere, the most important are in Finke (*op. cit*, from the Aragonese archives) and K Schottmüller (*Untergang des Templerordens,* 1887, from the Vatican archives). The Rule of the Temple has several times been published, the most convenient edition is that of H de Curzon, *La Règle du Temple* (1886); *see* also Maillard du Chambure, *Règle et statutes secrets des Templiers* (1840). In addition to the works already mentioned, the following may be named: M Lavocat, *Procès des frères et de l'ordre du Temple* (Paris, 1888); G. Schnürer, *Die ursprüngliche Templerregel* (1903); C. G. Addison, *The Knights Templars* (3rd ed. 1854), which contains a valuable account of the suppression of the order in England; Marquis d'Albon, *Cartulaire général de l'Ordre du Temple* (1922); G. Lizerand (ed.), *Le Dossier de l'affaire des Templiers* (1923). (W. A. P., X)

TEMPLE, FREDERICK (1821–1902), English divine, archbishop of Canterbury, was born in Santa Maura, one of the Ionian Islands, the son of Major Octavius Temple. He was educated at Blundell's School, Tiverton, and at Balliol College, Oxford. The "Tractarian Movement" had set in five years before he went up to Oxford, but the memorable tract, No. 90, had not yet been written. After much discussion and reflection he drew closer to the camp of "the Oxford Liberal Movement." In 1842 he took a "double-first" and was elected fellow of Balliol, and lecturer in mathematics and logic. Four years later he took orders, and with the aim of helping forward the education of the very poor, he accepted the headship of Kneller Hall, which served at that time for the training of masters of workhouse and penal schools. But the experiment was not altogether successful, and Temple himself advised its abandonment in 1855. He then accepted a school-inspectorship, which he held until he became headmaster of Rugby in 1858. In the meantime he had attracted the admiration of the prince consort, and in 1856 he was appointed chaplain-in-ordinary to the queen. In 1857 he was select preacher at his university.

At Rugby Temple showed great energy and bold initiative. Whilst making the school a strong one on the classical side, he instituted scholarships in natural science, built a laboratory, and gave importance to that side of the school work. He had the courage also to reform the games, in spite of all the traditions of the playing fields. His school sermons were deeply impressive: they rooted religion in the loyalties of the heart and the conscience, and taught that faith might dwell secure amid all the bewilderments of the intellect, if only the life remained rooted in pure affections and a loyalty to the sense of duty. Two years after he had taken up his work at Rugby *Essays and Reviews* appeared. The first essay in the book, "The Education of the World," was by Dr. Temple. Temple refused, so long as the storm lasted, to comply with the request that he would repudiate his associates, and it was only at a much later date (1870) that he saw fit quietly to withdraw his essay. In the meantime, however, he printed a volume of his Rugby sermons, to show definitely what his own religious positions were. His appointment by Gladstone as bishop of Exeter in 1869 raised a fresh storm.

G. A. Denison, archdeacon of Taunton, Lord Shaftesbury, and others formed a strong committee of protest, whilst Pusey declared that "the choice was the most frightful enormity ever perpetrated by a prime minister." At the confirmation of his election counsel was instructed to object to it, and in the voting the chapter was divided. But Gladstone stood firm, and Temple was duly consecrated on Dec. 21, 1869. On the death of Dr. John Jackson in 1885, he was translated to London, the appointment gave general satisfaction. In 1884 he was Bampton Lecturer, taking for his subject "The Relations between Religion and Science." In 1885 he was elected honorary fellow of Exeter College, Oxford.

Temple led a strenuous life as bishop of London. His normal working day at this time was one of fourteen or fifteen hours, and he was felt by many of his clergy and by candidates for ordination to enforce almost impossible standards of diligence and efficiency. The working classes instinctively recognized him as their friend When, in view of his growing blindness, he offered to resign the bishopric, he was induced to reconsider his proposal, and on the sudden death of Archbishop Benson in 1896, though now seventy-six years of age, he accepted the see of Canterbury.

As archbishop he presided in 1897 over the decennial Lambeth Conference. In the same year Temple and his brother archbishop issued an able reply to an encyclical of the pope which denied the validity of Anglican orders. In 1900 the archbishops again acted together, when an appeal was addressed to them by the united episcopate, to decide the vexed questions of the use of incense in divine service and of the reservation of the elements. After full hearing of arguments they gave their decision against both the practices in question. During his archbishopric Dr. Temple was deeply distressed by the divisions which were weakening the Church of England, and many of his most memorable sermons were calls for unity. His first charge as primate on "Disputes in the Church" was felt to be a most powerful plea for a more catholic and a more charitable temper, and again and again during

the closing years of his life he came back to this same theme. While speaking in the House of Lords on Dec. 2, 1902 on the Education Bill of that year, he was seized with sudden illness, and, though he revived sufficiently to finish his speech, he never fully recovered, and died on Dec. 23, 1902. He was interred in Canterbury cathedral four days later.

See Archdeacon E. G. Sandford, *Frederick Temple: an Appreciation* (1907), with biographical introduction by William Temple; *Memoirs of Archbishop Temple,* by "Seven Friends," ed. E. G. Sandford (1906).

TEMPLE, RICHARD GRENVILLE-TEMPLE, 1ST EARL (1711–1779), English statesman, eldest son of Richard Grenville (d. 1727) of Wootton, Buckinghamshire, was born on Sept. 26, 1711. His mother was Hester (*c.* 1690–1752), daughter, and ultimately heiress, of Sir Richard Temple, Bart. (1634–1697), of Stowe, Buckinghamshire, and sister of Richard Temple, Viscount Cobham, whose title she inherited under a special remainder in 1749; in the same year, her husband having been long dead, she was created Countess Temple. Her son, Richard Grenville, was educated at Eton, and in 1734 was returned to parliament as member for the borough of Buckingham. In 1752, on the death of his mother, he inherited her titles together with the estates of Stowe and Wootton; and took the name of Temple in addition to his own surname of Grenville. By the marriage of his sister Hester with William Pitt, afterwards earl of Chatham, Temple's career was linked with that of his brother-in-law.

In November 1756 Temple became first lord of the admiralty in the ministry of Devonshire and Pitt. He was disliked by George II., who dismissed both him and Pitt from office in April 1757. But when the coalition cabinet of Newcastle and Pitt was formed in June of the same year, Temple received the office of privy seal. He alone in the cabinet supported Pitt's proposal to declare war with Spain in 1761, and they resigned together on Oct. 5. From this time Temple became one of the most violent and factious of politicians, and it is difficult to account for the influence which he exerted over his brother-in-law. He was at variance with his younger brother, George Grenville, when the latter became first lord of the treasury in April 1763, and he had no place in that ministry; but the brothers were reconciled before 1765, when Temple refused to join the government, and persuaded Pitt to refuse likewise.

By 1765, however, the old friendship between the brothers-in-law was dissolving; and when at last in July 1766 Pitt consented to form a government, Temple refused to join, being bitterly offended because, although offered the head of the treasury, he was not to be allowed an equal share with Pitt in nominating to other offices. Temple forthwith began to inspire the most virulent libels against Pitt; and in conjunction with his brother George he concentrated the whole Grenville connection in hostility to the government. After George Grenville's death in 1770 Lord Temple retired almost completely from public life. He died on Sept. 12, 1779.

See *The Grenville Papers* (1852), a considerable portion of which consists of Earl Temple's correspondence; Horace Walpole, *Memoirs of the Reign of George II.,* 3 vols. (1847); *Memoirs of the Reign of George III.,* 4 vols. (1845 and 1894); Earl Waldegrave, *Memoirs 1754–58* (1821); Sir N. W. Wraxall, *Historical Memoirs,* ed. H. B. Wheatley, 5 vols. (London, 1884); *Correspondence of Chatham,* ed. W. S. Taylor and J. H. Pringle, 4 vols. (1838–40); W. E. H. Lecky, *History of England in the Eighteenth Century,* vols. ii. and iii. (7 vols., 1892).

TEMPLE, SIR WILLIAM, BART. (1628–1699), English statesman, diplomatist, and author, was born in London. He was the eldest son of Sir John Temple (1600–1677), Irish master of the rolls, whose father was Sir William Temple (1555–1627), provost of Trinity college, Dublin. Temple was educated at the grammar-school at Bishop Stortford, and at the Puritan college of Emmanuel at Cambridge, where he came under the influence of Cudworth. In 1647 he started to travel abroad. In the Isle of Wight he met Dorothy Osborne, the daughter of the Royalist governor of Guernsey, Sir Peter Osborne; and though her family were opposed to the match, he married her in 1655.

In 1660 Temple sat in the convention parliament, and in its successor, at Dublin as member for Carlow. He removed to England in 1663, attached himself to Arlington, secretary of state, and two years later was employed in various negotiations on the continent. In 1666 he became the English representative at the viceregal court at Brussels. While the Dutch war continued, Temple's duties consisted chiefly in cultivating good relations with neutral Spain, which was threatened by the claims of Louis XIV. on the Spanish Netherlands. Louis's designs became apparent in the spring of 1667, when he marched an army into Flanders. This event was one of those which led to the peace of Breda, and to the subsequent negotiations, which are Temple's chief title to fame. The French conquests were made at the expense of Spain, but were almost equally dangerous to the United Netherlands, whose independence would have been forfeited had Louis succeeded in annexing Flanders. While the French were taking town after town, Temple made a journey into Holland and visited De Witt.

Temple had for some time pressed on his government the necessity of stopping the French advance, and had pointed out the way to do so, but it was not till December 1667 that he received instructions to act as he had suggested. He at once set out for The Hague, and in January 1668 a treaty was made between England and the United Netherlands, which, being joined shortly afterwards by Sweden, became known as the Triple Alliance. It was a defensive treaty, made against the encroachments of France. The skill and celerity with which the negotiations were conducted and the results of the treaty, reflect great credit on Temple. The French king was checked in mid-career, and, without a blow being struck, was obliged to surrender almost all his conquests.

Unfortunately the policy thus indicated was undone by Charles's personal policy embodied in the secret treaty of Dover which reversed the policy of the Triple Alliance. (*See* CHARLES II.) Meanwhile Temple had developed the good understanding with the Dutch by contracting a commercial treaty with them (February 1668), and had acted as English plenipotentiary at Aix-la-Chapelle, where peace between France and Spain was made in May 1668. Shortly afterwards he was appointed ambassador at The Hague. Here he lived for two years on good terms both with De Witt and with the young prince of Orange, afterwards William III. The treaty of Dover led to Temple's recall, but Temple nominally held his post for another year. He perceived, however, that his day was over and retired to his house at Sheen. In June 1671 he received his formal dismissal. The war with the Netherlands broke out next year, and was almost as discreditable to England as that of 1665. Want of success and the growing strength of the opposition in parliament forced Charles to make peace, and Temple was commissioned to carry through the change of front. After a negotiation of three days, carried on through the medium of the Spanish ambassador, the treaty of Westminster was made (February 1674).

As a recognition of his services Temple was now offered the embassy to Spain. This he declined, as well as the offer of a far more important post, that of secretary of state, but accepted instead a renewal of his embassy to The Hague. In the March following he was nominated ambassador to the congress at Nijmwegen; but, owing to the tortuousness of Charles's dealings, it was not till July 1676 that he entered that town. The negotiations dragged on for two years longer, for Charles was still receiving money from France, and English mediation was no more than a ruse. In the summer of 1677 Temple was summoned to England and received a second offer of the secretaryship of state, which he again declined. In the autumn of the same year he had the satisfaction of bringing about the marriage of William and Mary, an event which seemed to complete the work of 1668 and 1674. Louis still remaining obstinate in his demands, Temple was commissioned in July 1678 to make an alliance with the states, with the object of compelling France to come to terms. This treaty was instrumental in bringing about the general pacification which was concluded in January 1679.

This was Temple's last appearance in the field of diplomacy. His plan for the reform of the privy council failed. His name was removed from the list of the council in 1681, and thenceforward he lived in retirement, first at Sheen, and then at Moor Park

in Surrey. When William III. came to the throne Temple was pressed to take office, but refused. His son became secretary at war, but committed suicide immediately afterwards. Temple died at Moor Park on Jan. 27, 1699.

Temple's works include *An Essay on the Present State and Settlement of Ireland* (1668); *The Empire, Sweden,* etc., a survey of the different Governments of Europe and their relations to England (1671); *Observations upon the United Provinces* (1672); *Essay upon the Original and Nature of Government* (1672); *Essay upon the Advancement of Trade in Ireland* (1673). Some of these were published in the first part of his *Miscellanea* (1679). In the same year apparently his *Poems* were privately printed. In 1683 he began to write his *Memoirs* The first part, extending from 1665 to 1671, he destroyed unpublished, the second, from 1672 to 1679, was published without his authority in 1691; the third, from 1679 to 1681, was published by Swift in 1709

See *Life and Works of Sir William Temple* (2 vols, 1720; 2nd ed, with *Life* by Lady Giffard, 1731); a more complete edition, including the *Letters,* was published in 4 vols in 1814, Burnet, *History of his own Time;* T P. Courtenay, *Memoirs of the Life, etc, of Sir William Temple* (2 vols., 1836); Macaulay, *Essay on Sir William Temple;* A. F Sieveking, *Sir W. Temple and other Carolean Essays* (1908); and E. S. Lyttel, *Sir William Temple* (Oxford, 1908).

TEMPLE, WILLIAM (1881–), English divine, second son of Frederick Temple, archbishop of Canterbury (*q.v*), was born at Exeter on Oct. 15, 1881, and educated at Rugby and at Balliol College, Oxford, where he was president of the Oxford Union. From 1904–10 he was fellow and lecturer in philosophy at Queen's College, Oxford. In 1914 he resigned the headmastership of Repton School, which he had held from 1910, to take charge of St. James's, Piccadilly During this period (1915–18) he was editor of *The Challenge.* He resigned from St. James's in 1917, and was then made a canon of Westminster (1919), and in 1921 bishop of Manchester For 16 years (1908–24) he was president of the Workers' Educational Association, to which he rendered powerful assistance. In Nov. 1928 he was appointed archbishop of York to succeed Dr Lang

TEMPLE, a city of Bell county, Texas, U S A, 73 m. N by E. of Austin, on Federal highway 81, and served by the Missouri-Kansas-Texas and the Santa Fe railway systems. Pop. (1920) 11,033 (19% negroes), estimated locally at 18,000 in 1928. It is the trade centre and shipping point for a rich agricultural region, raising chiefly cotton, grain and live stock Its cotton gins and compresses handle 70,000 bales in a normal season. There are railway shops and other manufacturing industries, with a total output in 1925 valued at $2,674,301. Temple was founded in 1881 by the Gulf, Colorado and Santa Fe Railway company, and was chartered as a city in 1884 Since 1922 it has had a commission-manager form of government.

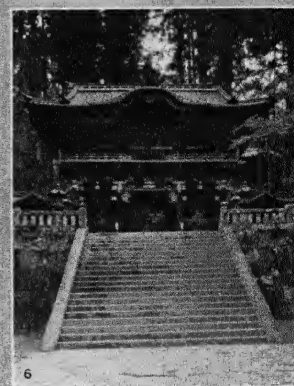
TEMPLE, a word signifying, loosely, any enclosed space or structure erected for purposes of worship, or to protect a cult image or cult objects In a figurative sense the word is used for (1) any shrine; (2) any building built in a style similar to that of a classic temple; (3) for the meeting houses of certain nonconformist denominations; (4) for synagogues; (5) for the meeting places of certain fraternal orders

Cave Temples.—Although perhaps antedated by existing temple remains of the earliest Chaldean and Egyptian periods, a primitive type of cave temple culturally much earlier is that of certain cave temples of the Mediterranean basin, of which the most remarkable are those on the island of Malta, apparently dating originally to a neolithic culture, although undoubtedly in use for a thousand years afterwards. It is remarkable that in these temples, despite their early date (?5000 B.C), great care is shown in the decoration and finish of altar stones, doors and other important features, and that many steatopygous female statues were found in the temples This, together with the large size and important position of many phallic stones, would seem to indicate that the temple was dedicated to a god or goddess of fertility, or perhaps to a pair. The most important sites are Hagar Kim, Hal Tarxien and Mnaidra. There is also at Hal Saflieni a large, neolithic series of caves which seem to have been both for habitation and worship; the presence of enormous numbers of human bones also indicates that part of it was used as an ossuary. The much later Egyptian cave temples at Abu Simbel (time of Rameses the Great) are merely highly developed descendants of such primitive cave structures, and the great groups of temple caves in India, as well as certain early cave temples along the Yangtse river, China, show that this tendency was wide spread.

High Places.—Not only do such primitive hill-top altars, common to many parts of western Asia, indicate the love for such positions, but also megalithic remains like those of Stonehenge (*q.v.*) indicate a similar feeling. It is noteworthy that even in China the great Temple of Heaven in Peking takes the form of a series of circular terraces, obviously pointing to a primitive desire to imitate hill forms, and the Assyrian ziggurat (*q.v.*), as well as the Mexican and Central American pyramids are merely variant expressions of the same controlling emotion. This probably explains the situation of the temple at Jerusalem upon the hill top, and, combined with ease of military defence and love of architectural effect, the site of the temples of the Greek cities.

Egyptian Temples.—With the civilization of Egypt the structural temple assumes a controlling importance, for the cave temples of Egypt are exceptional and secondary. The developed Egyptian temple shows a complex type which is evidently the accretion of many stages The earliest examples were probably simple, square or rectangular shrines of small size and with no openings but a door. Occasionally four columns supported the roof of flat stone. As worship grew more complex and wealth increased, additional halls were added in front of and around the original shrine, with a monumental, colonnaded hall open at the front, probably for the combined purposes of narthex (or vestibule) and prayer hall. Finally, a large court with entrance pylons of enormous size became part of the scheme, and by far the greater number of the Egyptian temples existing show all of these elements. The result was characteristic; both the widest and the highest elements in the building were toward the front (pylons, forecourt, hypostyle hall) and the narrowest and lowest at the rear (the shrine). The mystical effect of this gradual narrowing down and darkening of the interior scheme is impressive In addition to these simple elements, the great temples of Thebes (Karnak and Luxor), representing the building of many generations and many dates, have the shrines surrounded with a maze of small rooms, courts and corridors, whose use is difficult to assign. The most perfect example of Egyptian temples, so well preserved that its ancient effect can be readily judged, is the late temple at Edfu (237–257 B C.).

Western Asia.—The principal feature of Assyrian and Chaldean temples was the ziggurat (*q.v.*) or stepped pyramid, with stairs or an inclined plane leading up to the terraces of the steps and the summit The walls were decorated with glazed brick or painted stucco, and in some cases, at least, each stage was dedicated to a separate divinity, as in the famous example at Babylon, in which each of the seven stages was dedicated to a separate planet. It is undoubtedly to a ziggurat that the biblical tradition of the Tower of Babel refers. Besides a ziggurat the temple group comprised a court or courts and various rooms for priests and for the storage of temple treasures and archives. Further west, on the Mediterranean coast, a different type occurs, in which a small, enclosed room is fronted with a monumental entrance, frequently flanked by columns. This type is not only known from various small Phoenician models, but is also clearly represented in the biblical descriptions of the various temples at Jerusalem. The earliest description of Solomon's temple is that of I Kings, vi. 7, which, despite its completeness, is open to many interpretations and an enormous number of different restorations have been based upon it and indications found on the site. The essential elements are, however, clear and consist of a courtyard, a great altar of burnt offerings, traditionally placed upon the sacred rock now known as the *sakhra,* and the temple building itself. This was entered through a lofty porch or gateway of obviously Egyptian pylon type, which was flanked or fronted by two enormous free-standing columns, which were purely decorative or traditional and may represent a lingering of the same neolithic tradition that set the phallic stones in the Malta temples. Through the pylon one entered the naos (the holy place or *hēkāl*), 40 cubits long, 20 wide and 30 high (the cubit being roughly one and a half



PHOTOGRAPHS, (1-5) EWING GALLOWAY, (6) DE COU FROM EWING GALLOWAY

TEMPLE ARCHITECTURE FROM THE 5TH CENTURY B.C. TO THE 17TH CENTURY A.D.

1. The great entrance pylons of the temple at Edfu (237–57 B.C.). These pylons embody, despite their late Ptolemaic date, all of the magnificent grandeur of scale and elaborate construction characteristic of Egyptian religious architecture
2. Greek temples, on the other hand, sought and achieved repose and classic dignity through careful relationship of every portion. The Theseum at Athens, completed before 421 B.C. and probably once dedicated to Hephaestus and Athena, is one of the best preserved
3. The Roman variation of the classic temple form is well shown in the Maison Carré at Nimes, France (c. A.D. 1). Its high podium or base, entrance steps and superb Corinthian order are typical of the governed lavishness of the Roman genius
4. The Lama temple at Peking, China, in its carefully spaced columns, richly bracketed cornices and subtly curved roofs is characteristic of Northern Chinese tradition. Roof tiles of imperial yellow, columns lacquered deep red and cornices of brilliant green, blue and gold give the much sought after Chinese colour richness
5. The Subrahmanya shrine in the temple of the great pagoda at Tanjore, India, is a much later addition to the earlier 11th century temple, typical of the Dravidian style, in its strongly contrasted horizontal and vertical lines
6. The Yashamon gate of the tomb shrine of Iyemitsu at Nikko, Japan, shows the graciousness, intricacy and occasional over elaboration typical of the Tokugawa style of the middle of the 17th century

feet). It was lighted by a row of lattice windows, probably a clerestory set high in the wall, like the somewhat similar clerestory windows at Karnak. Behind the naos, and entered from it, was the Holy of Holies or *dĕbir*, 20 cubits in all three dimensions. Within this sanctuary was kept the Ark of the Covenant, flanked by two cherubim. Surrounding the naos and sanctuary were three storeys of small chambers. In the details described, this temple shows an interesting combination of forms with origins in all the surrounding countries. Thus the pylon porch and the diminution of height from front to back are purely Egyptian, while the greater number of the ornamental motives (cherubim, etc.) are of Mesopotamian origin. In construction, however, the combination indicated of stone, timber and metal is distinctively of the Mediterranean coast. The temple was destroyed (586 B.C.) and rebuilt 70 years later, largely in accordance with the older type, with certain differences, the most important of which was the use of a great curtain to separate the naos from the sanctuary and the existence of two courts instead of one. In *c.* 20 B.C. Herod built a third temple which was hardly completed in its entirety before the capture of the city and the razing of the temple by Titus (A.D. 70).

The Aegean World and Greece.—The Minoan civilization has left remains which indicate that both caves and high places were deemed sacred. Representations on seals and wall paintings also show that small shrines existed in great numbers, but up to the present time (1928) no large, monumental temples have been discovered. The most ordinary type of Aegean shrine of pre-Greek date is well represented on a fresco in the palace at Knossos (*c.* 1500 B.C.), showing a wall surrounding a temenos or sacred area, planted with trees, and filled with worshippers.

In the early Hellenic Greek world it would seem that the temenos with its altar was the most common form of temple; the constructed building not appearing until two or three centuries had elapsed after the Dorian migration. The earliest temples were of various forms, patterned on primitive dwellings, but the rectangular form was finally adopted and developed. The construction was apparently of sun-dried brick, with wall ends and openings cased in wood. A porch in front was early added, between solid end walls, which were the continuation of the side walls of the cella or enclosed portion. As building skill increased, and the need for larger and more splendid temples was felt, columns were added, first in one row down the centre, to decrease the unsupported span of the roof, and later in two rows, dividing the covered space into nave and aisles. On the outside columns on the porch matched those within. Later, another porch was added at the rear, and finally a colonnade would be continued entirely around the building, giving the developed type which has been famous as the characteristic classic type ever since. One of the earliest of large size, of which many remains exist, is the temple of Hera at Olympia (variously ascribed to many dates between the 10th and 7th centuries B.C.). Its stone foundations were obviously originally designed to carry sun-dried brick walls and its wood cased antae (*q.v.*), or pilaster-like wall ends, and door jambs are of the most primitive type. It is reported by Pausanius that the original wooden columns of the colonnade were replaced by stone columns of various shapes and sizes during the entire history of classic Greece, differences in contemporary styles accounting for the relative delicacy or crudity of the columns. Naturally, the greater number of the architectural fragments found are of late date. By the middle of the 7th century B.C. the Greek temple type was thoroughly established and the ruined temple at Corinth, of this date, had a stone colonnade in which all the elements of the later perfected Doric order are found. There is also a large group of archaic temples in south Italy and Sicily, where the Greek colonies of the time had reached a high level of wealth and established civilization. Thus at Syracuse, at Segesta, Selinus, Agrigentum (Acragas) and Paestum there are many examples of archaic Doric temples of the late 7th and 6th centuries B.C. In all of these the columns are heavy and low, closely spaced and with widely projecting, heavily convex capitals, and the entablature above is heavy in proportion. Sculpture of a crude type appears during this period, notably in the metopes and the pediments, or gable ends.

The type of temple building thus set remained constant throughout the history of Greek architecture, although the refinements of taste and growing structural skill of the period succeeding the Persian wars led to the use of slenderer columns and more delicate entablatures. The typical temple was surrounded by a colonnade, usually with six columns at each end, and with 12 or more on the sides. The walls of the enclosed cella were usually separated from the columns of the colonnade by a space wider than that between the columns and, following the old tradition, frequently projected in front of the doorway proper, forming, as it were, a little subsidiary porch inside the main colonnade. Within, the building was sometimes divided into two chambers, the larger in front, the smaller, rear chamber, being entered occasionally from the larger, but often, as in the Parthenon (447–438 B.C.), entered only from the rear porch. This rear chamber was frequently used as a treasury. The larger room was usually divided into a nave and aisles by two rows of columns, in most cases in two storeys, either with or without a gallery at the level of the lower entablature. At the end of the nave, opposite the entrance, stood the statue of the deity, which might be either an antique and shapeless tree trunk, going back to prehistoric times, or the most perfect colossal work of a sculptor like Pheidias, whose gold and ivory statues of Zeus in Olympia and of Athena in the Parthenon at Athens were perhaps the two most admired works of art of the ancient world. The interior was probably lighted only by light entering through the door; this illumination, upon the rich colours of the painted architectural detail and the mass of votive offerings, and reflected from the white and gold of the statue, undoubtedly produced an effect of sombre and impressive richness. The same richness of colour and sculpture decorated the exterior. The entablature glowed with deep blues and reds, against which the metope sculptures were sharply relieved. In the pediments above, great groups of free-standing sculpture, brilliantly composed, gave an adequate crown. In some cases the exterior walls were probably painted, as well.

The typical Greek temple, however, consisted usually of more than a single building, which was only the most important feature of the temenos. The sacred enclosure might contain, as well, smaller shrines of heroes or related deities; treasury buildings for gifts from special localities, like the treasuries at Olympia and Delphi; colonnades, as at Argos; and, in special cases, halls for mysteries and the like. Thus, such temples or sacred areas as those at Eleusis, Argos, Delos, Delphi and Olympia became vast congeries of all sorts of buildings devoted to the common purpose and use of aiding in some way the cult, and usually representing many periods of Greek history down to, and even later than, the Roman conquest.

In Asia Minor the Ionian influence, working on the same basis, produced effects of a different type. Not only was the Ionic order most commonly used in place of the Doric, but also the sense of scale was different, and when the Doric builders sought beauty through perfection of detail and every possible refinement, the Ionians sought it through enormous size and lavish richness. Thus even the archaic temple of Artemis at Ephesus (early 6th century B.C.) was of a scale scarcely ever attempted in Greece proper, prior to Roman times, and in the much later temples at Priene, Miletus and Sardis, great size and scale was the controlling force.

Etruria and Rome.—Etruscan temples are little known except from literary descriptions and certain remains of terra-cotta revetments, or covering decorations for wooden members. It is well established that the cella was much shorter than in Greek examples, approaching a square in plan, and that columns were limited to a porch in front, usually of great depth. The construction of the roof and entablature was apparently usually in wood, sometimes covered with terra-cotta plaques, and the spacing between columns was much greater than in Greek temples.

Roman temples, in plan, always retained the influence of their Etruscan prototypes, and the great temple of Jupiter on the Capitoline hill preserved to the end its primitive Etruscan lay out—a wide, shallow cella divided into three chambers, all opening out upon a deep, many-columned porch. The peripteral scheme, with columns on all four sides of the cella, appeared only in imperial

times and was always rare, being reserved for the very largest and most monumental temples, such as the enormous double temple of Venus and Rome at Rome, designed for Hadrian, by Apollodorus of Damascus. The normal type, with a porch only in front, nevertheless, frequently had the cella walls decorated with pilasters or engaged columns. Thus the temple of Fortuna Virilis at Rome (variously attributed to the beginning of the 2nd and the beginning of the 1st century B.C.), has a range of engaged columns around three sides of the cella, matching exactly the columns of the porch. The same treatment, on a much larger scale, is found in the Maison Carrée at Nîmes (c. A.D. 1), which is the most perfect example of a Roman temple extant. Similarly based upon Etruscan tradition is the fact that all Roman temples were raised upon high podia (base or pedestal), whose side walls projected forward and received the ends of a great flight of entrance steps. Roman temple interiors were usually both larger and more lavish than the interiors of Greek temples, and the larger examples were frequently vaulted with richly coffered barrel vaults. This led also to a greater enrichment of wall design, and walls, beside being cased in rich marbles, were often enriched with pilasters or engaged columns, and further decorated with small niches pediment-crowned and flanked by columns. The most extraordinary examples of this type of development extant are the temples comprising the great group at Baalbek in Syria, the ancient Heliopolis (begun during the reign of Hadrian and completed early in the 3rd century). The cella of the temple of Bacchus, the smaller of the group, still remains, in large measure complete up to the cornice, and shows ranges of engaged Corinthian columns, and between them arched recesses below, and pedimented statue frames above. The great temple of Jupiter is chiefly remarkable for its enormous forecourt, colonnaded and with great niches, and in front of that an hexagonal court, and the colonnaded propylaea. Both of these temples have colonnades all around, in the Greek manner, and the same is true of the contemporary double temple of Venus and Rome at Rome, in which the surrounding colonnade was double. This temple is also remarkable for the two apses back to back in which the statues of the two divinities were placed. The side walls were treated with niches and columns in a way much resembling the Baalbek example. The surroundings of Roman temples never had the informal charm of the Greek temenos, but were usually surrounded by a rectangular courtyard with colonnades, like that of the temple of Venus and Rome, or the temple of Apollo in Pompeii (rebuilt c. A.D. 65). Other temples were placed merely at street corners, like the temple of Fortune at Pompeii, of early imperial date, or the temple of Fortuna Virilis at Rome. Many temples were also placed in or facing the forum, which served, itself, as the temenos or sacred area.

Many exceptional types of Roman temples are found. Thus the temple of Vespasian at Brescia (A.D. 72) had three chambers in the cella with the six-columned portico in front of the central one projecting far beyond the small porticos of the side chambers. That of Concord, at Rome (7 B.C. to A.D. 10) had the main entrance to the cella in the middle of one of the long sides, with a superb portico in front of it. Remarkable also is the great development of round temples, either of comparatively small size, like the temple of the Sybil at Tivoli (usually attributed to the beginning of the 1st century B.C.); the so-called temple of Hercules at Rome, or the so-called temple of Venus at Baalbek, in which the cella is surrounded with a portico of Corinthian columns, whose entablature is scalloped or star-shaped in plan. The most magnificent of the round temples is the Pantheon (*q.v.*) at Rome (A.D. 110–125), whose vast domed hall, over 140 ft. in diameter, is one of the most impressive interiors in the world.

Classic Temples: Technical Definitions.—In architectural descriptions of the classic temple a number of technical words have become common. Many of these owe their origin to the work of Vitruvius, author of a complete Roman treatise on architecture of the time of Augustus. The most common of these terms descriptive of the general arrangement and of the position of columns may be shortly defined as follows:

A. Those affecting general distribution of parts.
- Prostyle—with a porch or portico in front.
- Amphiprostyle—with a porch or portico both at front and rear.
- Peripteral—with a colonnade completely surrounding the cella, either rectangular in plan, as in the typical Greek temple, or circular, as in the temple of the Sybil at Tivoli.
- Pseudoperipteral—with a porch or portico only in front, but with the exterior walls of the cella decorated by engaged columns or pilasters, as in the Maison Carrée at Nîmes.

B. Terms describing detailed arrangement or position of temple columns.
- In antis—columns placed between the pilaster-like decorations at the ends of the side walls of a naos or cella when these walls are projected forward beyond the front of the building to form a porch between them.
- Dipteral—with a double colonnade along the sides.
- Pseudodipteral—with the columns of the side colonnade separated from the cella walls by a space wide enough to allow a double colonnade but without an inner row of columns.
- Distyle, tetrastyle, pentastyle, hexastyle, octostyle, decastyle, etc.—with two, four, five, six, eight or ten columns in front. Such words composed of "style," with a Greek numerical prefix, may be multiplied indefinitely, to describe buildings or porticos with any number of columns.

Indian Temples.—Indian temples show clearly the development from sacred cave to free-standing structure. The earliest existing monumental temples are all rock-cut and developed with caves. The earlier temples, such as those at Behar, and at Karli, near Bombay, show a great cave interior, divided by piers or columns into nave and aisles, with a small stupa, or solid masonry curve-topped structure enclosing a relic of Buddha, and a façade cut in the face of the rock, with doorway below and huge horseshoe-shaped window above, all in imitation of wooden construction. A second common type of rock-cut temple consists of those in which, in addition to the shrine proper, there are great courtyards surrounded by cells for monks. These are known as *viharas*. The most remarkable groups of cave temples are those at Ajanta and Ellora. In both there are temples of Buddhism and also Brahmanism, and the types of detail known as Dravidian and Jain are both found. The dates vary from the 2nd century B.C. to the 6th and 7th centuries A.D. The Dravidian and Jain constructed temples both show a power and heaviness of general mass with an amazing intricacy of carved detail that is more typical of rock-cut than free-standing structures, and the characteristic pyramidal towers, with their strongly marked horizontal mouldings and vertical projections have almost the character of artificial mountains and cliffs. The rôle played by figure sculpture in its lavishness, its multitude of figures and their bold relief, is unlike that played in any other structural style, and without doubt owes much, also, to rock-cut prototypes. The plan type shows usually a vast rectangular enclosure entered through several monumental gateways, crowned with enormous, solid towers. Within are smaller enclosures and subsidiary buildings, and sometimes an additional closed court, also with monumental gates. Near the centre is the shrine proper, containing the cult statue, sometimes approached by vast, colonnaded halls, and every exposed surface of the great towers and the interior columns and walls is covered with a rich network of sculpture and ornament.

East Indies.—Indian influence is marked in the temple ruins found in scattered places through Cambodia, Burma, Java and nearby islands. All of the great temples are elaborations of the stupa idea, and consist in essence of one or more stupas on raised terraces. Thus in the Shwe Dagon pagoda at Rangoon there are a multitude of small stupas crowned with high, spire-like finials, surrounding a central stupa which rises to a height of over 350 ft., and the whole surface is heavily gilded. At Boro-Budur, Java, the great Buddhist temple (? 7th or 8th century

A.D.) consists of a series of terraces around a hill 150 ft. high, at the top of which is a large stupa surrounded by 16 smaller ones. All of the stone lining of the terrace walls is covered with exquisite relief sculpture, not only illustrating the life of Buddha, but also containing many pictures of ordinary, every day events. The most remarkable of these eastern Buddhist temples is Angkor-Wat at Angkor in Cambodia (attributed to the 1st half of the 12th century, and apparently originally intended as a Brahmin temple, being converted to Buddhist uses later). This consists of three great symmetrical terraces with elaborate stairs, corner towers, porticos and colonnaded halls, with a great stupa-like tower as the climax in the centre. The sculpture and ornament, although typically Khmer, show distinct traces of Hindu influence. The extremely classic character of some of the pier and column capitals is noteworthy.

China and Japan.—Further east an entirely contradictory tradition governs temple design, that of the columned prayer halls of Japan and China. The expression of this in China differs from that in Japan. The typical Chinese temple, whether Taoist or Buddhist, is basically symmetrical and rectangular. Through a gate-house, frequently vaulted, an outer court is entered, in which on either side of the main axis is a small tower, one containing a drum and the other a bell. Directly opposite is the main prayer hall of the temple, with many columns, and a richly beamed and coffered ceiling. Against the back wall is a large pedestal, usually supporting three statues, and in front of it a table-like altar with its ritual utensils. In temples of Confucius, a simple, richly decorated shrine replaces the statues. There is often, in addition, a court at the rear, with another hall shrine on its axis. In large groups, the number of courts and shrines is increased and additional halls at the sides of the courts serve the purpose of chapels. In Taoist temples, the most important shrine is sometimes in the centre of the court, and bell and drum towers are absent. There is also, at times, a long gallery containing statues of the 500 Lohans, or holy men. The architectural character varies with the locality. Those in the north are full of the monumental grandeur of the Peking school, as in the temple of Confucius, or such monasteries in the western hills as that of Wo Fu Tsu (both of the Ming and subsequent dynasties). Those in the Yangtse valley are more picturesque, with exaggeratedly curved roofs, and slimmer supports, as in the 18th century Sheng Yan Sze monastery near Hangchow. In those in the south, granite supports replace the wooden columns found further north. Roof ridges are of extraordinary intricacy and the wood carvings of the interiors exquisitely rich and delicate, as in the 18th century temple of the Chen family in Canton.

In Japan the elaborate formality of the typical Chinese temple is absent. In fact, the native Shinto temples are based upon exceedingly primitive house ideas, and are simple, rectangular buildings with heavily thatched roofs. Architectural effect is gained, however, through the monumental *torii* or gateways which cross the main entrance paths. Many votive stone lanterns also decorate the grounds. In the Buddhist temples the halls themselves are based entirely on Chinese prototypes, but the detail is typically Japanese in its composition and its mannered realism, and roof and cornice details are endlessly varied. In disposition there is little attempt at absolute symmetry. Instead, there is a brilliant grasp of informal balance and composition, and a remarkable genius in adapting the exigencies of the plan to the picturesque hillside site so loved by the Japanese. Outstanding examples are the temples of the magnificent group at Nikko, largely of the 17th century, and the Hong Wanji temple at Kyoto. The genius for placing temples is well seen in the island temples that dot the Inland sea, especially those of the sacred island of Itaku Shima, near Hiroshima, where the chief temple was founded in 587.

(T. F. H.)

TEMPLE BAR, an historic site in London, England. In more than one of the main roads converging upon the city of London a bar or chain marked the extra-mural jurisdiction of the Corporation. Temple Bar stood at the junction of the present Strand and Fleet street, over against the Law Courts. A bar is first mentioned here in 1301, but the name is most familiar in its application to the gateway designed by Sir Christopher Wren, which replaced an older structure on this spot in 1672. This was removed in 1878, and set up in 1888 at the entrance to Theobalds park near Cheshunt, Hertfordshire. A pedestal surmounted by a dragon or "griffin" marks the old site. When the sovereign is about to enter the city in state, whether by Temple Bar or elsewhere, the Lord Mayor, in accordance with ancient custom, presents the sword of the city to him, and he at once returns it. Formerly the bar or gate was closed until this ceremony was carried out.

TEMPO (It.), term used in music signifying literally time, though in practice it has come to mean more often the speed at which a composition is, or should be, performed. It is however still used in the other sense in such expressions as *tempo ordinario,* meaning "in common time"; likewise in *tempo rubato* (literally "robbed time"), meaning the slight deviations from strict time which the performer makes for expression. (*See* TIME.)

TENANT: *see* LANDLORD AND TENANT.

TENANT-RIGHT, in law, a term expressing the right which a tenant has, either by custom or by law, against his landlord for compensation for improvements at the determination of his tenancy. In England it is governed for the most part by statute; *e.g.,* the Agricultural Holdings Act, 1923, and the Small Holdings and Allotments Acts, 1908–26 (*see* ALLOTMENTS; LANDLORD AND TENANT; SMALL HOLDINGS). A right to compensation for improvements is created in favour of tenants of business premises by the Landlord and Tenant Act, 1927. In Ireland tenant-right was a custom, prevailing particularly in Ulster, by which the tenant acquired a right not to have his rent raised arbitrarily at the expiration of his term. Tenants of houses and shops in urban districts, towns or villages in Ireland enjoy a statutory tenant-right to compensation for improvements and disturbance (*see* the Town Tenants [Ireland] Act, 1906).

No custom giving rise to tenant-right seems ever to have existed in the United States, and no right of compensation in favour of tenants exists apart from agreement or local statutes.

TENASSERIM, a division of Lower Burma, bordering on Siam. Area, 35,788 sq. miles. Pop. (1921) 1,613,523, including 55,883 Christians, the great majority of whom are Karens. The headquarters of the commissioner are at Moulmein. It is divided into six districts: Toungoo, Salween, Thatôn, Amherst, Tavoy and Mergui. It formed the tract south of Pegu conquered from Burma in 1826, which was for many years known as the Tenasserim province. The southern extremity of the division approaches the insular region of Malaya, and it is fringed along its entire western coast by a number of islands, forming in the north the Moscos and in the south the Mergui Archipelago. The eastern frontier is formed by a mountain range 5,000 ft. high, the water-parting between Tenasserim and Siam. (*See* BURMA.)

TEN BRINK, BERNHARD EGIDIUS KONRAD (1841–92), German philologist, of Dutch origin, was born at Amsterdam on Jan. 12, 1841, and educated at Düsseldorf, Münster and Bonn. In 1870 he became professor of modern languages at Marburg, and in 1873 professor of English at Strasbourg university. In 1874 he began to edit, in conjunction with W. Scherer, E. Martin and E. Schmidt, *Quellen und Forschungen zur Sprache und Kulturgeschichte der germanischen Völker.* In 1877 he published *Chaucer: Studien zur Geschichte seiner Entwickelung und zur Chronologie seiner Schriften;* in 1884, *Chaucers Sprache und Verskunst.* He also published critical editions of the *Prologue* and the *Compleynte to Pité.* Ten Brink's work stimulated a revival of Chaucer study in the United Kingdom as well as in Germany, and to him was indirectly due the foundation of the English Chaucer society. His *Beowulf-Untersuchungen* (1888) proved a hardly less valuable contribution to the study of Early English literature. His best known work is his *Geschichte der englischen Literatur* (1889–93) (English by H. Kennedy in Bohn's *Standard Library*), which was never completed, and broke off just before the Elizabethan period. He died at Strasbourg Jan. 29, 1892.

TENBY, municipal borough and seaside resort, Pembrokeshire, Wales, on a promontory on the south coast of the county. Pop. (1921) 4,832. Its two sandy beaches and mild climate contribute to its success as a watering-place. The settlement is first definitely mentioned as a Danish fishing station, and the old Welsh name is Dynbych-y-Pyscod (the "precipice of fishes"). The name Tenby may be derived from "Dynbych"; but is usually said to come from the Scandinavian "Daneby" Flemish cloth-workers came here in the early 12th century The earls-palatine of Pembroke often had to defend it from, and refortify it after, Welsh attacks. The town was associated with the Tudors during the Wars of the Roses and Jasper Tudor rebuilt its walls The early charters were confirmed by that of Elizabeth in 1580 and the walls were repaired in 1588 when a Spanish invasion was feared

During the 15th and 16th centuries Tenby traded by sea with Bristol and had wealthy mercantile families It declined after the Restoration. During the 18th century it was a market centre

The large parish church, St. Mary's, has a 13th century tower of local type, with spire, but is mostly 15th century. The ancient town walls are almost intact on the north and west. The ruins of the castle, part of the keep and outer walls, stand on Castle Hill, N.E of the town

TENCH (*Tinca tinca*). A cyprinid fish of Europe, Asia Minor and Siberia, greenish, with small scales and rounded fins It thrives in weedy ponds Specimens exceeding 8 lb are rare The flesh is more palatable than that of most cyprinids.

TENDA, the name given by the Fulani to the peoples known as Bassari, Koniagui and Badiar They call themselves Ayan, Awonhen or Akus, and live between the Upper Gambia and the Rio Nunez, in confederated villages, each village forming a political and a religious unit. They have three degrees of initiation to corresponding age classes, with a chief for each class, and a higher dignitary over all who in turn is subject to the paramount chief The women are organized into societies Marriage is prohibited between relations of the direct paternal or maternal line and collaterally within three degrees, but marriage is common between second cousins, the woman's consent is necessary. Family property is administered by the head of the family, and there is personal property Succession is based on maternal kinship, the eldest brother coming first, then younger brothers and finally nephews. The Tenda are excellent cultivators of millet, maize, earth-nut and tobacco, and breed oxen, sheep and goats

See Delacour, "Les Tenda," *Revue d'Ethnographie et de Sociologie* (1912–13).

TENDER. (1) An adjective meaning soft, either physically or figuratively (Fr. *tendre,* Lat *tener*, soft, allied to *tenuis*, thin). (2) A legal term meaning an offer for acceptance, particularly an offer in money for the satisfaction of a debt or liability or an offer to pay or deliver according to the terms of a contract; for "legal tender" *see* PAYMENT The term is also applied to an offer to do a specified piece of work or to supply certain goods for a certain sum or at a certain rate or to purchase goods at a certain rate. Contracts for important works or for the supply of large amounts of goods are usually put out to tender in order to secure the lowest price. In this sense the word is from "to tender," to offer (Fr. *tendre,* Lat *tendere*, to stretch out) (3) A "tender" is also one who "attends" (Lat *attendere,* to stretch towards, to give heed to), and so is applied particularly to a small vessel which brings supplies, passengers, etc., to a larger vessel or which is used to take or bring messages, and similarly to a carriage attached to a locomotive engine on a railway, which carries fuel and water

TENDON OF ACHILLES, the large tendon at the back of the ankle. It is the tendon of the calf muscles which extend and invert the foot, and is inserted into the heel bone (calcaneus). These muscles often become shortened, owing to overdevelopment, or sometimes to the continued use of high heels, or they may be congenitally short. This defect sometimes leads to fallen arches and foot pain so severe that the tendon has to be lengthened by surgical operation. This tendon is named after Achilles, a famous hero of the Trojan war. According to Greek legend when Achilles was born his mother plunged him into the river Styx. This made his whole body invulnerable except the part of the heel by which she had held him, and in this heel he later received a mortal wound.

TENEBRAE, an office sung in Roman Catholic churches on the afternoon or evening of Wednesday, Thursday, and Friday of Holy Week. Durandus (vi. 72, n. 2) derives the name from the fact that "the church on these days cultivates darkness (*tenebras colit*)" in sorrow for the Lord's Passion, celebrating his exequies on three days since for three days He was dead, and it symbolizes the darkness that fell on the earth while the Sun of justice was crucified.

TENERIFFE [Tenerife], the largest of the Canary islands; Pop. (1900) 138,008, area, 782 sq m It is of irregular shape, 60 m. long, with an extreme breadth of 30 m The celebrated peak, locally known as the Pico de Teyde (or Teide) with its supports and spurs, occupies nearly two-thirds of the whole island. It has a double top; the highest point, El Piton, is 12,200 ft. above the sea; the other, Chahorra, connected with the first by a short narrow ridge, has a height of 9,880 ft. They are both orifices in the same grand dome of trachyte. Snow remains for about four months on the upper part of the peak.

For more than one-half of its circumference the base of the true peak rises from an elevated but comparatively level tract. On the south-east, south and south-west there is a high curved ridge overlooking the Pumice-Stone Plains, and presenting a very steep face to the peak Between the ridge and the sea the slope is more gradual, and there are intervening tablelands Peaks rise from the ridge, one of which (Guajara) attains the height of 8,900 ft Both El Piton and Chahorra have craters on their summits, from which issue steam and a little sulphurous vapour The crater on El Piton is partly surrounded by a wall of lava, which has been made white by the action of sulphurous vapours The crater is about 300 ft across, with a depth of 70 ft. The crater on Chahorra has a diameter of 4,000 ft ; its depth is scarcely 150 ft. The entrance to the Llano at a sort of natural gateway (called *Portillo*) between two basaltic hills, is about 7,000 ft above the sea Between two and three hours are consumed in crossing the Llano to the base of the cone, the lower part of which is ascended to a point 9,750 ft above the sea

To the north-west of the grand cone, some thousands of feet below Chahorra, there are many small cones of eruption, showing that the intensity of volcanic action was greatest on this side Eastward from the ridge bounding the Pumice-Stone Plains extends a chain of mountains to the north-eastern extremity of the island. The highest peaks are Izana (7,374 ft.), Perejil (6,027), and Cuchillo (5,467)

There is no record of eruptions from either crater of the peak In 1795 a great quantity of lava was poured out from three vents on the eastern side; and in the same year lava streams issued from a crater near Guimar, half-way between Santa Cruz and the peak. In the year 1706 a vent on the north-western side of the peak discharged a copious stream, which flowed down to the sea, and nearly filled up the harbour of Garachico For three months in 1798 much lava and other volcanic matter were ejected.

Santa Cruz, the capital of Teneriffe and of the Canaries, and La Laguna, the former capital, are described in separate articles A good road connects Santa Cruz and Orotava, a town on the north coast 25 m W N W. Date-palms form a striking feature in the landscapes The town of Orotava (pop 9,192) is 1,040 ft above the sea. The houses are solidly built, but it has a deserted aspect A stream of water is conducted through every street. Port Orotava, 3 m N. of the town, is a clean place, with about 4,500 inhabitants The streets are broad and the houses well built. (*See* also CANARY ISLANDS)

TENGYUEH (Burmese MOMEIN), a town in the province of Yunnan, south-west China, near the Burmese frontier, with an estimated Chinese population of 18,000 It is situated at an elevation of 5,400ft., in a region of heavy monsoonal rainfall, between the parallel north to south valleys of the Salwen and Irrawaddy. The town dates from the 14th century, when the Shan principality of Nankao was conquered by the Chinese, and Tengyueh was built as an outpost. The town lies on the old trade

route from Yunnan-fu to Bhamo, a Burmese trade-centre in the upper Irrawaddy valley. Trade is conducted by mule-transport; the journey to Yunnan-fu, over difficult country, takes about 24 days, while Bhamo is a seven days' journey. The town was opened to foreign trade in 1897, but the actual customs opening did not take place until 1902. Foreign piece goods, cotton yarn, kerosene oil and matches are imported, while there is an export trade in carpets, musk, split bamboo hats and Szechuan raw silk. In times of difficulty, as in 1926, the Szechuan silk is exported via Szemao, a neighbouring frontier port. In 1925 (a normal year) the net foreign imports were valued at 3,701,194 Haikwan taels, and the exports at 1,755,263 taels.

TENIERS, the name of a family of Flemish artists who flourished at Antwerp and Brussels during the 17th century.

David Teniers, the elder (1582–1649), was born at Antwerp, the son of Julian Teniers, a mercer who settled at Antwerp in 1558. He received his first training in the painter's art from his brother Juliaen, then studied under Rubens in Antwerp, and subsequently under Elsheimer in Rome; he became a member of the Antwerp gild of painters in 1606. Though he tried his skill in large religious, historical and mythological compositions, his fame depends chiefly on his landscapes and paintings of peasants carousing, of kermesse scenes and the like, which are marked by a healthy sense of humour, and which are not infrequently confused with the early works of his son David. A large painting by the elder Teniers at St. Paul's church in Antwerp, represents the "Works of Charity." At the Vienna Gallery are four landscapes painted by Teniers under the influence of Elsheimer, and four small mythological subjects, among them "Vertumnus and Pomona," and "Juno, Jupiter and Io." The National Gallery has a characteristic scene of village life, "Playing at Bowls," a "Conversation," and a "Rocky Landscape." Other examples of his work are to be found at the galleries of Leningrad, Madrid, Munich, Dresden and Berlin ("The Temptation of St. Anthony"). He died at Antwerp on July 29, 1649.

David Teniers, the younger (1610–1690), his more celebrated son, was born in Antwerp and was baptized on Dec. 15, 1610. Through his father, he was indirectly influenced by Elsheimer and by Rubens. We can also trace the influence of Adrian Brouwer at the outset of his career. In 1637 Teniers married the ward of Rubens, Anne Breughel, the daughter of John (Velvet) Breughel. He became a "master" in the gild of St. Luke in 1633. The Berlin Museum possesses a group of ladies and gentlemen dated 1634. Some first-rate works—the "Prodigal Son" and a group of "Topers" in the Munich Gallery, and a party of gentlemen and ladies at dinner, termed the "Five Senses," in the Brussels Museum—are instances of the perfection attained by the artist when he was probably scarcely twenty. His touch is of the rarest delicacy, his colour at once gay and harmonious. He was little over thirty when the Antwerp gild of St. George enabled him to paint the marvellous picture now in the Hermitage Gallery in Leningrad —the "Meeting of the Civic Guards." Correct to the minutest detail, yet striking in effect, the scene, under the rays of glorious sunshine, displays acquired knowledge and natural good taste. Another work of the same year (1643), now in the National Gallery, London, is "The Village Fête."

Teniers was chosen by the common council of Antwerp to preside over the gild of painters in 1644. The archduke Leopold William, who had assumed the government of the Spanish Netherlands, employed Teniers not only as a painter but as keeper of the collection of pictures he was then forming. With the rank and title of "ayuda de camara," Teniers took up his abode in Brussels in 1651. Immense sums were spent in the acquisition of paintings for the archduke. A number of valuable works of the Italian masters, now in the Vienna Museum, came from Leopold's gallery after having belonged to Charles I. and the duke of Buckingham. De Bie (1661) states that Teniers was some time in London, collecting pictures for the duke of Fuensaldaña, then acting as Leopold's lieutenant in the Netherlands. Paintings in Madrid, Munich, Vienna and Brussels show what the imperial residence was at the time of Leopold, who is represented as conducted by Teniers and admiring some recent acquisition. No picture in the gallery is omitted, every one being inscribed with a number and the name of its author, so that the *ensemble* of these paintings might serve as an illustrated inventory of the collection. Still more interesting is a canvas, now in the Munich Gallery, showing Teniers at work in the palace, with an old peasant as a model and several onlookers. When Leopold returned to Vienna, the pictures travelled to Austria. Teniers remained in high favour with the new governor-general, Don Juan, a natural son of Philip IV.

Shortly after the death of his wife in 1656 Teniers married Isabella de Fren, daughter of the secretary of the council of Brabant, and strove to prove his right to armorial bearings. In 1663 Teniers founded the Academy at Brussels.

Teniers died in Brussels on April 25, 1690. David, his eldest son, a painter of talent and reputation, died in 1685. One of this third Teniers's pictures—"St. Dominic Kneeling before the Blessed Virgin," dated 1666—is in the church at Perck.

Teniers* (1877); J. van den Branden, *Gesch. d. Antw. Schilderschool* (1883); A. Rosenberg, *David Teniers* (Leipzig, 1901).

TENISON, THOMAS (1636–1715), English archbishop, was born at Cottenham, Cambs., on Sept. 29, 1636. He was educated at Corpus Christi college, Cambridge, of which he became a fellow in 1639. After holding cures at Cambridge, where he gave devoted care to sufferers from the plague, and at Norwich, he was presented in 1680 by Charles II. to the vicarage of St. Martin's-in-the-Fields, London, where he endowed schools, established a public library, and was a champion of Protestantism during the reign of James II. Monmouth sent for him before his execution. Under William III., Tenison was in 1689 named a member of the ecclesiastical commission appointed to prepare a reconciliation of the Dissenters, the revision of the liturgy being specially entrusted to him. He preached a funeral sermon on Nell Gwyn (d. 1687) in which he represented her as truly penitent—a charitable judgment which did not meet with universal approval. He was made bishop of Lincoln in 1691 and archbishop of Canterbury in Dec. 1694. He attended Queen Mary during her last illness and preached her funeral sermon in Westminster Abbey. During William's absence in 1695 Tenison was appointed one of the seven lords justices to whom his authority was delegated. With Burnet he attended the king on his death-bed. He enjoyed little favour with Queen Anne, but was a commissioner for the Union with Scotland in 1706. A strong supporter of the Hanoverian succession, he was one of the three officers of state to whom on the death of Anne was entrusted the duty of appointing a regent till the arrival of George I., whom he crowned on Oct. 31, 1714. Tenison died in London on Dec. 14, 1715.

Tenison's works include *The Creed of Mr. Hobbes Examined* (1670) and *Baconia, or Certain Genuine Remains of Lord Bacon* (1679). He was one of the founders of the Society for the Propagation of the Gospel.

TENNESSEE (tĕn″ẹ-sē′), popularly known as the "Volunteer State," is a S. central State of the American Union. It lies between lat. 35° and 36° 40′ N. and between long. 81° 37′ and 90° 28′ W. of Greenwich. Tennessee is bounded on the north by Kentucky and Virginia; on the east by North Carolina along the line of the crest of the Unaka mountains to within 26 m. of Georgia, where the boundary turns due south; on the south by Georgia, Alabama and Mississippi along the 35th parallel of N. lat.; on the west by the Mississippi river, which separates it from Arkansas and Missouri. The extreme length of the State from E. to W. is 432 m., and the extreme breadth is 109 m.. its area being 42,022 sq.m., of which 335 are water surface. The popular name "Volunteer State" was given to Tennessee because of her remarkable record in furnishing volunteers in the Civil War.

Physical Features.—The State is popularly divided into three large divisions known as east, middle and west Tennessee. The first extends from the heights of the Unaka ridges along the North Carolina border, across the valley of the Tennessee river to the heights of the Cumberland plateau. The middle section includes

a part of the Cumberland plateau, all the Highland Rim plateau and the Central basin, and extends westward to the Tennessee river. The western division includes the plateau region from the Tennessee river to the precipitous escarpment overlooking the Mississippi Flood plain; also a narrow strip of low land which extends to the Mississippi river. From a maximum elevation of 6,680 ft. at Mt. Le Conte near the North Carolina border, in Sevier county, the surface descends to 182 ft. on the Mississippi river in Shelby county. The mean elevation of the State is approximately 900 feet. The general slope, however, is west by north. The Unaka mountains, which occupy a belt 8 to 10 m. wide along the State's eastern border, are a series of somewhat irregular ridges developed on complexly folded and faulted crystalline rocks. Sixteen peaks exceed 6,000 ft. in height. That part of the Great Appalachian valley which traverses Tennessee is commonly known as the valley of East Tennessee. It consists of parallel ridges and valleys developed by erosion on folded sandstones, shales and limestones, the valley quality predominating because the weak limestones were of great thickness. The valley areas vary in height from 600 ft. in the south-west to 1,400 ft. in the north-east. In the north-east the ridges are more numerous and higher than in the south-west, where White Oak ridge and Taylor's mountain are among the highest, although Missionary and Chickamauga ridges are better known, because of their association with battles of the Civil War. Along the north-west border of the valley a steep escarpment, known as the Cumberland Scarp, rises to the Cumberland plateau This plateau has a mean elevation of about 1,800 ft., is only slightly rolling, and the northern portion slopes gently toward the north-west. The western edge of the plateau is much broken by deep indentations of stream valleys, and drops suddenly downward about 1,000 ft. to the Highland Rim plateau, so named from the scarp formed by its western rim about the Central and (farther north) Louisville basins It is fairly level generally except where it is cut by river valleys The Central basin, with a more rolling surface, lies for the most part 400 to 600 ft. below the Rim; a few hills or ridges, however, rise to the level of the Rim. The Basin is elliptical in form, extending nearly across the State from north-east to south-west with an extreme width of about 60 m , near its centre is the city of Murfreesboro, and Nashville lies in the north-west. Westward from the lower Tennessee river the surface of the East Gulf Coastal plain rises rapidly to the summit of a broken *cuesta* or ridge and then descends gently and terminates abruptly in a bluff overlooking the Mississippi Flood plain The eastern slope, about a quarter of the length of the western slope, is steep and rocky, and the western slope is broken by the valleys of numerous streams The bluff, 150 to 200 ft. in height, traverses the State in a rather straight course; between it and the meandering Mississippi, except at a few points where that river touches it, lie low bottom lands varying in width according to the bends of the river and containing numerous swamps and ponds In the northern portion, principally in Lake county, is Reelfoot lake, which occupies a depression formed by an earthquake in 1811. It is 18 m. long, has a maximum width of 3 m , and is the only large lake in the State

The whole of the Appalachian province of Tennessee and the southern portion of the Cumberland plateau, the Highland rim, and the Central basin are drained southward and westward by the Tennessee river and its tributaries. The valley of the lower Tennessee is drained northward by the same river. The northern portion of the Cumberland plateau, Highland rim and Central basin is drained northward and westward by the Cumberland river and its tributaries The western slope of the East Gulf plains is drained directly into the Mississippi by several small streams

The Central basin, the less elevated parts of the valley of East Tennessee and parts of the outer portion of the Highland rim have a fertile soil of limestone origin. There are narrow strips of rich alluvium along many other rivers. The soils on the mountains, on the ridges of the valley of East Tennessee, and on the eastern slope of the East Gulf plains vary greatly, according to the rocks from which they are derived. In the Cumberland plateau, in the inner portion of the Highland rim and in the western slope of the East Gulf plains, there is for the most part a light sandy soil, much of it too poor for cultivation.

Tennessee has a delightful climate. The mean summer temperature varies according to elevation from 62° F. on the Unaka mountains to 72° on the Cumberland plateau, or 75° in the valley of East Tennessee and on the Highland rim, 77° in the Central basin, and about 78° on the East Gulf plains. The mean winter temperature for each of these divisions varies little from 38°, and the mean annual temperature ranges only from 57° in East Tennessee to 58° in Middle Tennessee and to 60° in West Tennessee. Usually the highest temperatures of the year are in July and the lowest in January. Killing frosts are rare, especially in the southern and western parts of the State, between the third week in April and the middle of October An average annual precipitation of about 50 in is quite equally distributed over the State, and a little more than one-half of it is well distributed through the spring and summer months. The average annual snowfall is about 8 inches. The warm, moisture-bearing winds blow low from the south or south-west with a free sweep across the State in a direction nearly parallel with the trend of the mountains. The commingling of these winds with upper cold currents from the north gives rise frequently to westerly and occasionally to easterly winds

Government.—With the exception of the administrative changes made in 1923, few alterations have been made in the Government of Tennessee since the present Constitution was adopted in 1870; and this was only a revision of the State's second Constitution, which was adopted in 1834 Every attempt to amend or revise the existing Constitution has been unsuccessful, because of the difficult procedure involved in such changes. Amendments may be proposed not oftener than once in six years by a majority of the members elected to each house of the legislature, but before an amendment can be adopted, it must be agreed to by two-thirds of the members elected to each house of the next succeeding legislature, and later by a majority of all the citizens of the State voting for representatives at the next regular election. The legislature may also submit to the people the question of calling a convention to amend or revise the Constitution, and such a convention must be called whenever, upon the submission of this proposition, a majority of the votes are cast in favour of it. The election of the governor, members of the general assembly and congressmen is held biennially, in even-numbered years, on the first Tuesday after the first Monday in November, but the election of judicial and county officers is held on the first Thursday in August.

The governor is the only State executive officer elected by the people. He is elected for a term of two years and is not eligible for more than three consecutive terms. There is no lieutenant-governor; in case of a vacancy in the office of governor, the speaker of the senate becomes acting governor. The secretary of State and comptroller of the treasury are elected by a joint ballot of the senate and the house of representatives, each for a term of two years; the attorney-general is appointed by the judges of the supreme court for a term of eight years. In 1923 the administrative system of the State was reorganized, 64 boards, commissions, agencies, etc., being combined into nine departments, each with a commissioner at its head. These are known as the departments of Insurance and Banking; Highways and Public Works; Labour; State Institutions; Agriculture; Finance and Taxation; Railroads and Public Utilities; Public Health; and Education.

Both senators and representatives are elected for a term of two years by counties or by districts having approximately the same population. The number of representatives is limited by the Constitution to 99, and the number of senators to one-third the number of representatives. The legislature meets biennially, in odd-numbered years, on the first Monday in January, and the length of the session is limited by a provision that the members shall be paid four dollars a day, besides an allowance for travelling expenses, for a period not exceeding 75 days; when the governor calls an extra session, they are paid for not more than 20 days Bills of whatever character may originate in either house, but no bill can become a law until it has passed both houses by a majority

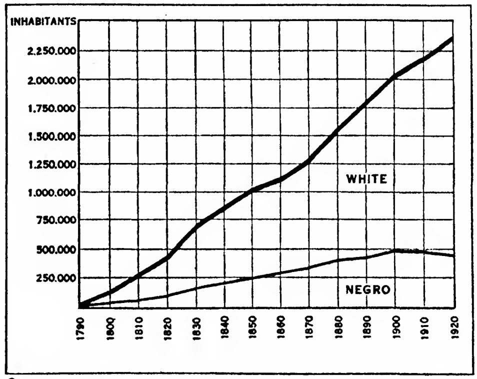
of all the members to which the house is entitled under the constitution, and if the governor vetoes a bill it cannot become a law until it has again passed both houses by such a majority. The Constitution provides that no minister or priest is eligible to a seat in either house of the legislature.

The administration of justice is vested in a supreme court, a court of civil appeals, chancery courts, circuit courts, criminal courts, county courts, justice of the peace courts, and, in certain cities and towns, a recorder's court. The supreme court consists of five judges elected by the State at large for a term of eight years, one for each of the three grand divisions (Eastern, Middle and Western) and two for the State at large. The judges designate one of their number to preside as chief justice. The court has appellate jurisdiction only. The court of civil appeals, which in 1907 was substituted for the court of chancery appeals, is composed of nine judges elected for a term of eight years. This court has jurisdiction of appeals from equity courts in which the amount in controversy does not exceed $1,000, except in cases involving the constitutionality of a Tennessee statute, a contested election, State revenue or an ejectment suit; it has jurisdiction also of civil cases tried in the circuit and common law courts in which writs of error or appeals in the nature of writs of error are applied for. It may transfer any case to the supreme court. The state is divided into 13 chancery districts, in each of which a chancellor is elected for a term of eight years, and at every county seat in each district a court of chancery is held; exceptions are the 10th district, which has three chancellors, and the 15th, which has four. There are also ten criminal judges, principally in the larger cities, and there is one probate judge in the city of Memphis. The State is also divided into 19 circuits, in each of which a circuit judge is elected for a term of eight years, and at every county seat in each circuit a circuit court is held. In several of the counties the county court is composed of a county judge, elected for a term of eight years, together with the justices of the peace in the county, and in the other counties it consists of the justices of the peace alone, who elect a chairman. Each county is divided into civil districts, varying in number according to population or other factors, and each district elects at least two justices of the peace for a term of six years; each county town or incorporated town also elects one justice of the peace. A recorder has concurrent jurisdiction with a justice of the peace.

The government of each county is vested principally in the county court. This body represents and acts for the county as a corporation; has charge of the erection and repair of county buildings; levies the county taxes; divides the county into highway districts, and chooses a highway commissioner for each district for a term of two years; and chooses a superintendent of schools (except where this is done by popular ballot), a surveyor, a public administrator and public guardian, a board for the equalization of taxes, a coroner, and a county physician or health officer, each for a term of two years, three commissioners of the poor for terms of three years (one chosen each year), and a keeper and sealer of weights and measures to serve during the pleasure of the court. A county trustee, whose duty it is to collect State and county taxes, and a sheriff are elected by the people of the county for a term of two years; a clerk of the county court and a registrar are also elected by the voters of the county for a term of four years. The capital city of Tennessee is Nashville.

Population.—The population in the census of selected years was as follows: 35,691 in 1790; 105,602 in 1800; 681,904 in 1830; 1,002,717 in 1850; 1,542,359 in 1880; 1,767,518 in 1890; 2,020,616 in 1900; 2,184,789 in 1910; 2,337,885 in 1920. The population on July 1, 1928, was 2,502,000, according to the United States census estimate. The increase of population in the decade 1910–20 was 153,096, or 7%, as compared with 8·1% in the preceding decade. The negro population during 1910–20 decreased numerically from 473,088 to 451,758, and decreased proportionally from 21·7% of the total to 19·3%. The average density of population in 1920 was 56·1 per sq.m.; in 1910 it was 52·4. The urban population (in places of 2,500 inhabitants or more) increased from 20·2% of the total in 1910 to 26·1% in 1920. The population of the chief cities in 1920 and 1927 was as follows: Memphis, 162,351 and 244,500 (estimate); Nashville, 118,342, and 147,000; Knoxville, 77,818, and 102,100; Chattanooga, 57,895, and 96,000; Jackson, 18,860, and 25,000; Johnson City, 12,442 and 28,128.

Finance.—In common with the other States of the Union, Tennessee has had a great increase in State expenditures. Also as in other States, highway expenditures rank first, and educational second in importance. The chief sources of revenue are: motor-car licences and other revenue of the highway department, a general property tax, a gas-privilege tax, a State tax on insurance companies, a sales tax on tobacco, an excise tax and an inheritance tax. Various privilege taxes, fines and forfeitures also help to augment the State's revenue. The property assessment for 1926 was $1,724,357,940, on which a rate of 25 cents per $100 gave the State a tax of $6,431,089. The gross receipts for the fiscal year July 1, 1926, to June 30, 1927, were $27,191,448; the disbursements for the same period were $26,185,582. Some of the chief disbursements for the fiscal year July 1, 1926, to June 30, 1927, were as follows: highways, $13,751,274; education, $5,616,156; charitable institutions, $2,850,206; pensions (soldiers and widows), $731,547; State debt and interest, $835,748. The funded indebtedness of the State, as on June 30, 1927, was $14,572,000.



GRAPH OF GROWTH OF POPULATION IN TENNESSEE, 1790–1920, SHOWING RELATIVE PROPORTIONS OF WHITES AND NEGROES AT EACH CENSUS

Education and Charities.—The first steps toward the creation of a common-school system for Tennessee were taken in 1823, when an act was passed setting aside for school purposes, the revenue and taxes accruing from public lands. From that beginning until the adoption of a uniform school code in 1925, more than 1,000 different acts were passed pertaining to the educational system. Under the new code the administration is vested in a State commissioner of education; a State board of education, consisting of the commissioner, the governor and nine other members; a county superintendent and a county board in each county; and in cities, city boards of education. The commissioner and the other members of the State board are appointed by the governor. The county superintendent is elected biennially by either the county court or by popular ballot. The county board consists of seven members (unless otherwise provided), elected by the county court for a term of seven years, one retiring annually.

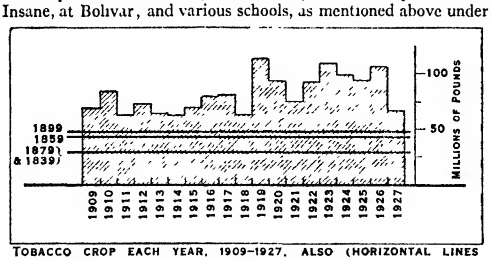
The State board of education conducts examinations for county superintendents and issues certificates of qualification, classifies the high schools, maintains and controls the State teachers' colleges and establishes a salary schedule. No teacher may receive pay from the public school funds unless he or she has received a certificate from the State commissioner of education. The quarterly county court has power to issue bonds, levy taxes and provide funds for buildings for the county schools. The court is under obligation to maintain at least one four-year high school within the county.

Public schools are free to all persons above the age of six years; attendance is compulsory between the ages of seven and 16 unless

high-school standing has been attained. Separate schools are maintained for the white and for the coloured. In 1927 the scholastic population between six and 17 years of age, inclusive, was 601,407. On the same date 649,007 were enrolled in the public elementary and secondary schools Of these, 590,126 were in kindergarten and elementary schools and 58,881 were in secondary schools. In 1924 there were 22,900 pupils enrolled in private and parochial schools The average length of school term for rural public schools increased from 110 days in 1915 to 154 days in 1927. From 1900 to 1925 the *per capita* expenditure for public schools based on population between five and 17 years of age, inclusive, increased from $6 32 to $23 61 Illiteracy among persons over ten years of age decreased from 13 6% in 1910 to 10 3% in 1920

The State provides for higher education in the University of Tennessee, at Knoxville, the Polytechnic Institute, at Cookeville; East Tennessee Teachers college, at Johnson City, Middle Tennessee Teachers college, at Murfreesboro, and West Tennessee Teachers college, at Memphis The Agricultural and Industrial Normal college for negroes is at Nashville Other schools maintained by the State are. a school for the deaf, at Knoxville, a school for the blind, at Nashville, Tennessee Industrial school, at Nashville; Tennessee Girls' Vocational school, at Tullahoma; State Training and Agricultural school for boys at Nashville, and a vocational school for coloured girls at Nashville Peabody college for teachers, at Nashville, founded and maintained chiefly with proceeds of the George Peabody fund for the improvement of education in the south, is State controlled. Other institutions of higher learning not under the control of the State are Vanderbilt university (non-sectarian), at Nashville; University of the South (Episcopal), at Sewanee; Southwestern Presbyterian college, at Memphis; Cumberland university (Presbyterian), at Lebanon; Union university (Baptist), at Jackson; Christian Brothers' college (Catholic), at Memphis, Bethel college (Presbyterian), at McKenzie, University of Chattanooga (Methodist), at Chattanooga, Milligan college (Christian), at Milligan; Carson-Newman (Baptist), at Jefferson City, Lincoln Memorial university (non-sectarian), at Cumberland Gap, Tusculum college (non-sectarian), at Greenville, King college (Presbyterian), at Bristol, Maryville college (Presbyterian), at Maryville; Bryson college, at Fayetteville, and Tennessee college, at Murfreesboro Education for the coloured is provided by Fisk university, at Nashville, Lane college, at Jackson; Le Moyne Institute, at Memphis; and Knoxville college, at Knoxville

The State maintains a Confederate Veterans' Home near Nashville, on the "Hermitage," the estate formerly belonging to Andrew Jackson; the Eastern hospital for the Insane, at Knoxville, Central hospital for the Insane, at Nashville; Western hospital for the Insane, at Bolivar, and various schools, as mentioned above under



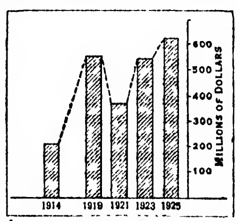
TOBACCO CROP EACH YEAR, 1909–1927, ALSO (HORIZONTAL LINES CROSSING THE FIGURE) IN 1839, 1859, 1879 AND 1899

"Education" The main penitentiary is located on a farm of 4,000 ac near Nashville Another penitentiary, known as Brusby Mountain prison, is located in the coal region in East Tennessee. The prisoners are kept at labour principally in the State coal-mines, on the farm, or at mechanical employment within the prison walls Contract labour was not entirely abolished until 1917 All charitable and corrective institutions are under the supervision of the department of State institutions

Industry, Trade and Transport.—The interests of the State remain predominantly agricultural, though manufacturing is developing rapidly. The total land area in farms decreased from 20,041,657 ac. in 1910 to 17,901,139 ac. in 1925. The number of farms increased from 246,012 in 1910 to 252,669 in 1925; from 1910 to 1925 the average acreage per farm decreased from 81·5 to 70 4 The farm population decreased from 1,271,708 in 1920 to 1,173,316 in 1925 Of the 252,669 farmers in 1925, 218,022 were white and 34,647 were negroes. Of all farmers in 1925, 148,627 were owners; 103,718 were tenants, and 324 were managers. In 1920 there were 11,374 women farmers. The total value of farm crops in 1919 was $318,285,307; in 1926, it was $175,614,000. In 1926 Tennessee ranked 22nd among the States of the Union, in total value of farm products. The following table shows the comparative acreage, production and value of six important crops for 1919 and 1927:

Crop	Year	Acreage	Production	Value
				$
Indian corn	1919	3,301,075	70,639,252 bu.	127,150,649
	1927	2,944,000	70,656,000 „	58,644,480
Oats	1919	162,417	2,413,409 „	2,534,082
	1927	179,000	3,043,000 „	1,826,000
Wheat	1919	684,497	6,362,357 „	14,506,174
	1927	528,000	3,696,000 „	5,137,000
Hay and forage	1919	1,751,123	1,907,345 tons	49,649,657
	1927	1,402,000	1,822,000 „	27,114,000
Cotton	1919	807,770	306,974 bales	48,808,866
	1927	943,000	345,000 „	32,775,000
Tobacco	1919	138,561	112,367,567 lb	24,720,869
	1927	81,500	71,435,000 „	12,858,000

The number and value of the principal domestic animals on Jan. 1, 1927 were cattle, 912,000, valued at $27,816,000; swine, 968,000, valued at $12,584,000; sheep, 300,000, valued at $3,030,000, horses, 219,000, valued at $11,826,000, and mules, 352,000, valued at $24,288,000 The three national forests that lie in part in Tennessee had, in 1925, a total area of 267,939 ac within the State According to the United States Bureau of Mines, Tennessee ranked 25th among the 48 States in the value of minerals produced in 1925 In that year the production had a value of $38,869,198 The principal products in order of value were coal, cement, clay products and stone The coal-producing area is a belt running from north-east to south-west, a little east of the centre of the State, production being reported in 16 counties Valuable building marble is quarried in the eastern part of the State. Tennessee produces most of the copper mined in the Southern States Its entire production of copper, gold and silver comes from mines worked primarily for copper in Polk county. Rock phosphate is mined in five counties in the central and south-central sections of the State The most important products, in 1925, were coal, 5,454,011 short tons, worth $10,077,000, clay products exclusive of pottery, worth $3,941,395; stone, 1,835,150 short tons, worth $4,334,891; copper, 19,788,234 lb, worth $2,809,929; rock phosphate, 464,240 long tons, worth $2,334,995, zinc, 16,256 short tons, worth $2,470,912. Other products of economic value are. sand and gravel, lime, iron ore, barite, lead, gold, silver and petroleum (*see* PETROLEUM).



AVERAGE VALUE OF MANUFACTURED PRODUCTS AT EACH CENSUS, 1914–1925

Manufacturing is growing rapidly in Tennessee. In 1925 there were 2,162 establishments, employing 107,645 wage-earners; the wages amounted to $95,255,480. The value of the products was $601,488,472, as compared with $546,499,264 in 1923 and $374,038,000 in 1921. The chief industries according to value of product were: knitted goods, $44,006,467; food preparations, $40,297,255; timber products, $35,527,699; flour and grain mill products, $31,810,028; construction and repair in steam railway shops, $26,711,694, planing-mill products, $26,086,641; cotton

goods, $23,706,355; cotton-seed oil, meal and cake, $23,045,442; printing and publishing, $21,404,448; chewing and smoking tobacco and snuff, $16,819,438.

The steam railway mileage of Tennessee increased continuously until 1920, when the total was 4,078, but by 1925 this had decreased to 4,063. The chief railways operating in the State in 1925 were: Louisville and Nashville; Nashville, Chattanooga and St. Louis; Southern Railway; Tennessee Central; and Illinois Central. In the above year there were 417 m. of electric railway within the State, operated chiefly as city systems. The navigable waterways include the Mississippi, Tennessee and Cumberland rivers. The State highway department controlled 5,051 m. of roadways in 1927, of which 3,555·5 m. were surfaced. New surfacing placed during the year amounted to 291·7 miles.

HISTORY

Exploration and Early Settlements.—What is now Tennessee was visited and claimed in turn by Spaniards, French and English. The final success of the English was achieved only after the desperate struggle which ended in the Treaty of Paris of 1763. By its provisions France was driven from North America and the power of Spain was greatly limited.

The daring Spanish explorer Hernando de Soto reached the Mississippi river in 1541, at a high bluff occupied by Chickasaw villages, believed to be the present site of Memphis. After a brief halt to collect food from the Indians and to build rafts, De Soto left the territory by crossing the Mississippi. It was 132 years before another white man saw Tennessee. The French missionary and explorer Father Marquette, in his voyage down the Mississippi by canoe in 1673, camped upon the western border, and eight years later La Salle and his companions left Canada to complete the exploration of the river. La Salle built Ft. Prud'homme in 1682 upon the Chickasaw Bluff, near the present site of Memphis, but it was soon abandoned. Later the French built Ft. Assumption, where Memphis now stands, and kept a garrison there, but made no attempt at colonization. The territory was a part of the English grant to Sir Walter Raleigh in 1584, and of the later Stuart grants, including that in 1663 to the proprietors of Carolina. James Adair, of South Carolina, a fur trader and explorer, is supposed to have been the first to go from the English colonies into Tennessee. A party of Virginians led by Dr. Thomas Walker (1715–94) in 1750 reached the Cumberland river and Cumberland mountains and named them in honour of the royal duke. In 1756 or 1757, Ft. Loudon, named in honour of John Campbell, earl of Loudon, was built on the Little Tennessee river, about 30 m. south of the present site of Knoxville, as an outpost against the French who were now active in the whole Mississippi valley, and was garrisoned by royal troops. The fort was captured by the Cherokee Indians in 1760, and both the garrison and the neighbouring settlers were massacred.

Eastern Tennessee was recognized as a common hunting-ground by the Cherokees, Creeks, Miamis and other Indian tribes. The Iroquois of New York claimed much of the central portion by right of conquest, and the western section was the home of the Chickasaws. By the treaty of Ft. Stanwix, in 1768, the Iroquois ceded whatever claim they had to the English, and in 1769 several cabins were built along the Holston and Watauga rivers upon what was thought to be Virginia soil. A settlement near the present Rogersville was made in 1771, and in the next year another sprang up about the store of Jacob Brown on the Nollichucky. After the failure of the Regulator insurrection in North Carolina in 1771, hundreds of the Regulators made their way into the wilderness. A survey of the western boundary-line between Virginia and North Carolina showed the settlements to be in North Carolina, but that colony made no effort to assert jurisdiction nor to protect the settlers from Indian depredations. Therefore in 1772 the residents of the first two settlements met to establish a form of government since known as the Watauga Association. A general committee of 13 was elected to exercise legislative powers. This committee elected from its members a committee of five in whom executive and judicial powers were lodged. A sheriff, an attorney and a clerk were elected, and regulations for recording deeds and wills were made. Courts were held, but any conflict of jurisdiction with Virginia or North Carolina was avoided. In 1775 the settlement on the Nollichucky was forced to join the association, and in the same year the land was bought from the Cherokee Indians in the hope of averting war. With the approach of the American Revolution, the dream of becoming a separate colony with a royal governor was abandoned, and on petition of the inhabitants the territory was annexed to North Carolina in 1776 as the Washington district, which in 1777 became Washington county, with the Mississippi river as the western boundary. The population increased rapidly, and soon several new counties were created.

During the American Revolution the hardy mountaineers under John Sevier and Evan Shelby did valiant service against both the royal troops and the Loyalists in South Carolina, chiefly as partisan rangers under Charles McDowell (1743–1815). Major Patrick Ferguson, with several hundred Loyalists and a small body of regulars, made a demonstration against the western settlements; but at King's Mountain in South Carolina, he was completely defeated by the Americans.

Relations with North Carolina.—After the American Revolution the legislature of North Carolina in 1784 offered to cede her western territory to the general Government, provided the cession be accepted within two years. The Watauga settlers, indignant at this transfer without their consent, and fearing to be left without any form of Government whatever, assembled in convention at Jonesboro on Aug. 23, 1784, and chose delegates to a later convention to form a new State. Meanwhile North Carolina repealed the act of cession and created the western counties into a new judicial district. A second convention, in November, broke up in confusion without accomplishing anything; but a third adopted a Constitution, which was submitted to the people, and ordered the election of a legislature. This body met early in 1785, elected Sevier governor of the new State of Franklin (at first Frankland), filled a number of offices, and passed several laws in anticipation of an autonomous existence. On account of the scarcity of a circulating medium more than 20 articles were valued and declared legal tender. Among them were fox skins, 1s. 6d.; beaver skins, 6s.; bacon, 6d. per lb.; rye whisky, 2s. 6d. the gallon. Four new counties were created, and taxes were levied. Later in the year another convention, to which the proposed Constitution had been referred, adopted instead the Constitution of North Carolina with a few trifling changes, and William Cocke was chosen to present to Congress a memorial requesting recognition as a State. Congress, however, ignored the request, and the diplomacy of the North Carolina authorities caused a reaction. For a time two sets of officials claimed recognition, but when the North Carolina legislature a second time passed an act of oblivion and remitted the taxes unpaid since 1784, the tide was turned. No successor to Sevier was elected. He was arrested on a charge of treason, but was allowed to escape, and soon afterwards was again appointed brigadier-general of militia.

Meanwhile, settlers had pushed on farther into the wilderness. On March 17, 1775 Col. Richard Henderson and his associates extinguished the Indian title to an immense tract of land in the valleys of the Cumberland, the Kentucky and the Ohio rivers (*see* KENTUCKY). In 1778 James Robertson (1742–1814), a native of Virginia, who had been prominent in the Watauga settlement, set out with a small party to prepare the way for permanent occupation. He arrived at French Lick (so called from a French trading post established there) early in 1779, and in the same year a number of settlers from Virginia and South Carolina arrived. Another party, led by John Donelson, arrived in 1780, and after the close of the War of Independence the immigrants came in a steady stream. A form of Government similar to the Watauga Association was devised, and blockhouses were built for defence against the Indians. Robertson was sent as a delegate to the North Carolina legislature in 1783, and through his instrumentality the settlements became Davidson county. Nashville, which had been founded as Nashborough in 1780, became the county seat. Finally, in 1843, it became the State

capital. Robertson, the dominant figure in the early years, struggled to counteract the efforts of Spanish intriguers among the Indians, and when diplomacy failed, he led the settlers against the Indian towns

Tennessee Becomes a Separate State.—On Feb. 25, 1790 North Carolina again ceded the territory to the United States Government, stipulating that all the general provisions of the ordinance of 1787 should apply except that forbidding slavery Congress accepted the cession and, on May 26, 1790, passed an act for the government of the "Territory south of the River Ohio." William Blount was appointed the first governor, and in 1792 Knoxville became the seat of Government The chief events of Blount's administration were the contests with the Indians, the purchase of their lands, and the struggle against Spanish influence A census ordered by the Territorial legislature in 1795 showed more than 60,000 free inhabitants (the number prescribed before the Territory could become a State), and accordingly a convention to draft a State Constitution met in Knoxville on Jan. 11, 1796. The instrument, which closely followed the Constitution of North Carolina, was proclaimed without submission to popular vote. John Sevier was elected governor, and William Blount and William Cocke United States senators. In spite of the opposition of the Federalist party, whose leaders foresaw that Tennessee would be Republican, it was admitted to the Union as the 16th State on June 1, 1796.

With the rapid increase of population, the dread of Indian and Spaniard declined. Churches and schools were built, and soon many of the comforts and some of the luxuries of life made their appearance The question of a circulating medium was acute during the first half of the 19th century, and State banks were organized, which suspended specie payments in times of financial stringency. The bank of Tennessee, organized in 1838, had behind it the credit of the State, and it was hoped that money for

MADISON AVENUE, THE WALL STREET OF MEMPHIS, LOOKING EAST

education and for internal improvements might be secured from its profits. The management became a question of party politics, and during the Civil War its funds were used to advance the Confederate cause. The development of the western section along the Mississippi was rapid after the beginning of the century. Memphis, founded in 1819, was thought as late as 1832 to be in Mississippi, and not until 1837 was the southern boundary, which according to the North Carolina cession was Lat. 35°, finally established As in other river towns, the disorderly element in Memphis was large, and the gamblers, robbers and horse thieves were suppressed only by local vigilance committees The peculiar topographical conditions made the three sections of the State almost separate commonwealths, and demand for better means of communication was insistent The policy of State aid to internal improvements found advocates very early, in spite of the Republican affiliations of the State, but a definite programme was not laid out until 1829, when commissioners for internal improvements were appointed and an expenditure of $150,000 was authorized In 1835 the State agreed to subscribe one-third to the capital stock of companies organized to lay out turnpikes, railways, etc, and four years later the proportion became one-half Though these agreements were soon repealed, the general policy was continued, and in 1861 more than $17,000,000 of the State debt was due to these subscriptions, from which there was little return

Though President Andrew Jackson was for many years practically a dictator in Tennessee politics, his arbitrary methods and his intolerance of any sort of independence on the part of his followers led to a revolt in 1836, when the electoral vote of the State was given to Hugh Lawson White, then United States senator from Tennessee, who had been one of Jackson's most devoted adherents White's followers called themselves anti-Van Buren Democrats, but the proscription which they suffered drove most of them into the Whig party, which carried the State in presidential elections until 1856, when the vote was cast for James Buchanan, the Democratic candidate The Whig party was so strong that James K Polk (Democrat), a resident of the State, lost its electoral vote in 1844 With the disintegration of the Whig party, the State again became nominally Democratic, though Union sentiment was strong, particularly in East Tennessee. There were few large plantations and few slaves in that mountainous region, while the middle and western sections were more in harmony with the sentiment in Mississippi and Alabama In 1850 representatives of nine Southern States met in a convention at Nashville (*q v*) to consider the questions at issue between the North and the South The vote of the State was given for Bell and Everett in 1860, and the people as a whole were opposed to secession

The Civil War.—The proposition to call a convention to, vote on the question of secession was voted down on Feb. 9, 1861, but after President Lincoln's call for troops the legislature submitted the question of secession directly to the people, and meanwhile, on May 7, 1861, entered into a "Military League" with the Confederacy. An overwhelming vote was cast on June 8 in favour of secession, and on the 24th Gov I G Harris (1818–97) issued a proclamation declaring Tennessee out of the Union. Andrew Johnson, then a United States senator from Tennessee, refused to resign his seat, and was supported by a large element in East Tennessee. A Union convention, including representatives from all the eastern and a few of the middle counties, met on June 17, 1861 and petitioned Congress to be admitted as a separate State The request was ignored, but the section was strongly Unionist in sentiment during the war, and has since been strongly Republican

The State was, next to Virginia, the chief battle-ground during the Civil War, and a historian has counted 454 battles and skirmishes that took place within its borders In Feb. 1862, General U. S. Grant and Commodore A. H. Foote captured Ft. Henry on the Tennessee river and Ft Donelson on the Cumberland The Confederate line of defence was broken and General D C. Buell occupied Nashville Grant next ascended the Tennessee river to Pittsburg, landing with the intention of capturing the Memphis and Charleston Railway, and on April 6 and 7 defeated the Confederates in the battle of Shiloh. The capture of Island No. 10 in the Mississippi on April 7 opened the river as far S. as Memphis, which was captured in June. On Dec. 31 and Jan. 2 General William S. Rosecrans (Federal) fought with General Braxton Bragg (Confederate) the bloody but indecisive battle of Stone river (Murfreesboro). In June, 1863 Rosecrans forced Bragg to evacuate Chattanooga. Bragg, however, turned upon his pursuer, and on Sept. 19 and 20 one of the bloodiest battles of the war was fought at Chickamauga. General Grant now assumed command, and on Nov. 24–25 defeated Bragg at Chattanooga, thus opening

the way into East Tennessee. There General A. E. Burnside at first met with success, but was shut up in Knoxville by General James Longstreet, who was not able, however, to capture the city, and on the approach of General W. T. Sherman retired into Virginia. Almost the whole State was now held by Federal troops, and no considerable military movement occurred until after the fall of Atlanta in Sept. 1864. Then General J. B. Hood moved into Tennessee, expecting Sherman to follow him. Sherman, however, sent reinforcements to Thomas and continued his march to the sea. Hood fought with General John M. Schofield at Franklin, and on Dec. 15–16 was utterly defeated by Thomas at Nashville, the Federals thus securing virtually undisputed control of the State.

Reconstruction and Politics.—After the occupation of the State by the Federal armies in 1862, Andrew Johnson was appointed military governor by the President (confirmed March 3, 1862), and held the office until he was inaugurated vice president on March 4, 1865. Republican electors attempted to cast the vote of the State in 1864, but were not recognized by Congress. Tennessee was the first of the Confederate States to be readmitted to the Union (July 24, 1866), after ratifying the Constitution of the United States with amendments, declaring the ordinance of secession void, voting to abolish slavery, and declaring the war debt void. Tennessee freed her own slaves by an amendment to the State Constitution ratified by a vote of the people on Feb. 22, 1865, but suffrage was not conferred upon the negro until two years later (Feb. 25, 1867). The State escaped "carpet bag" government, but the native whites in control, under the leadership of William G. Brownlow, exhibited almost every phase of the reconstruction policy. All persons who had either directly or indirectly taken part in the war against the Union or had given aid to the Confederacy were denied the right of suffrage. In the election of 1869, the acting governor, D. W. C. Senter, ordered the election commissioners to issue to all actual citizens of the State permits to vote. The Democrats united with the Conservative Republicans and Senter was easily elected. At the same time a Democratic and Conservative legislature was elected, thus placing the State Government again in the control of officers elected by the majority of the people. The Ku Klux Klan, originating in 1865 as a youthful prank at Pulaski, Tenn., spread over the State and the entire South, and in 1869 nine counties in the middle and western section were placed under martial law because of the Klan's activities against the Loyal League and the negroes. A constitutional convention, which met in Jan., 1870, revised the old Constitution, and the revision became the present Constitution when ratified by the people the following May. In 1873 a school law was passed which provided for State and county superintendents and separate schools for white and coloured children and levied a State tax to aid in paying the expenses of these schools. Another progressive step was the final compounding of the old State debt at 50 cents on the dollar by an act of the legislature in 1883. With the exception of the administration of Alvin Hawkins, 1881–83, the Democratic Party controlled the executive office from 1871 to 1911; but in 1890 the Farmers' Alliance was able to control the Democratic Party. In 1920, for the first time since 1868, the State's electoral votes were cast for the Republican candidate for President. The prohibition question long played an important rôle in State politics, and many acts were passed tending toward the abolition of the liquor traffic.

Twentieth Century Reforms.—In 1904 the Adams law, prohibiting the sale of intoxicating liquors in towns of 5,000 inhabitants or less, was passed, largely through the efforts of the Anti-Saloon League; an act prohibiting the manufacture of intoxicating liquor in the State became effective on Jan. 1, 1910; in Oct. 1913 Governor Hooper called a special session of the legislature and secured the passage of the so-called Nuisance Act, designed to close every saloon in the State by enforcing the law forbidding the sale of intoxicating liquor within four miles of any school; in 1915 provision was made for removal from office of State, county or city officials who failed to enforce the prohibition laws; and on Feb. 2, 1917, Governor Rye signed a bill forbidding the importation of liquor into the State. In 1915 a law was passed providing for mothers' pensions. In 1917 the letting of prison labour to private contractors was prohibited, and an act was passed forbidding the limiting of the output of coal in order to increase the price. In the same year a State budget commission was created. On Aug. 18, 1920, the house, by 50 to 46, voted for concurrence in the senate resolution (adopted on Aug. 13, by 5 to 4) ratifying the proposed amendment to the Federal Constitution, providing for woman suffrage. As the 36th State (out of the 48 in the American Union) to ratify, Tennessee brought the number to the requisite three-fourths. Many progressive school laws were passed in the years between 1913 and 1925, when the revised school code was adopted. Additional revenue was made accessible for all branches of education, better supervision was provided and ages for compulsory attendance were extended.

BIBLIOGRAPHY.—The best bibliography of material relating to Tennessee is *Calvin Morgan McClung Historical Collection* (Knoxville, 1921). There is no complete history of Tennessee that is entirely satisfactory. S. E. Scates, *A School History of Tennessee* (1925), gives a brief elementary survey up to 1925. *Tennessee, the Volunteer State, 1769–1923*, edited by J. T. Moore and Austin P. Foster (4 vols., 1923), is a more detailed work. Historical works of greater merit are: James Phelan, *History of Tennessee* (1888); W. R. Garrett and A. V. Goodpasture, *History of Tennessee* (1903); G. R. McGee, *A History of Tennessee from 1663 to 1919*; J. Haywood, *Civil and Political History* (1823; reprinted, 1891); J. G. M. Ramsey, *Annals* (1853); A. W. Putnam, *History of Middle Tennessee, or the Life and Times of General James Robertson* (1859); Theodore Roosevelt, *The Winning of the West* (1889–96); John Carr, *Early Times in Middle Tennessee* (1857); Edward Albright, *Early History of Middle Tennessee* (1908); Constance L. Skinner, *Pioneers of the Old Southwest* (1919). A confused mass of history and biography can be found in the following: W. T. Hale and D. L. Merritt, *A History of Tennessee and Tennesseans* (8 vols., 1913); Samuel G. Heiskell, *Andrew Jackson and Early Tennessee History* (3 vols., 1920–21); and Samuel C. Williams, *History of the Lost State of Franklin* (1924). For the Civil War period see *Report of Joint Committee on Reconstruction* (U.S. Public Documents, 1866); James W. Fertig, *Secession and Reconstruction of Tennessee* (1898); John R. Neal, *Disunion and Reconstruction in Tennessee* (1899); O. P. Temple, *East Tennessee and the Civil War* (1899). On administration *see* the *Reports* of the various administrative departments; *Tennessee Directory* (annual); *Baldwin's Cumulative Code Supplement, Tennessee* (1920); *Tennessee Statutes;* and J. W. Caldwell, *Studies in the Constitutional History of Tennessee* (1895; new ed., 1907). For education see *Public School Laws of Tennessee* (1925) and *Reports* of the State department of education. For population, agriculture and manufactures consult the *Fourteenth U.S. Census*, the *Agricultural Yearbook* and the volumes of the *Census of Manufactures*. The mineral resources and physical features are described in the *Reports of the Tennessee Geological Survey* (1840 *seq.*) and *Mineral Resources of the United States* (U.S. bureau of mines; annual). (C. E. A.)

TENNESSEE RIVER, the largest tributary of the Ohio river, U.S.A. It is formed by the confluence of the Holston and the French Broad rivers 4.5m. above Knoxville (Tenn.), flows south south-west to Chattanooga, there turns west through the Cumberland Plateau and into the north-east corner of Alabama, continues west across the northern part of Alabama, turns north on the boundary between Alabama and Mississippi, and continuing north across Tennessee and Kentucky unites with the Ohio at Paducah. Its principal tributaries rise in the Appalachian Mountains; the Holston and the Clinch on the mountain slopes that flank the Appalachian valley in western Virginia; and the French Broad, the Little Tennessee and the Hiwassee in the mountains of western North Carolina. The Tennessee itself is 652m. long, and with the Holston and the North Fork of the Holston forms a channel about 900m. long. Its drainage basin covers about 44,000sq.m., and its low-water discharge at Paducah is 10,600cu.ft. per second. Its average fall is 0·79ft. per m.—0·956ft. from Knoxville to Chattanooga; 1·19ft. from Chattanooga to Florence (Ala.), and 0·39ft. from Florence to its mouth. The banks are everywhere easily accessible except at Knoxville and Chattanooga, where, for short distances, high elevations rise precipitously, from the water; and as the banks are mostly of clay or rock the channel is permanent and the river is unusually free from silt. The Tennessee is navigable by steamboats throughout its entire course of 652m. for several months of the year.

In 1904 the Federal Government authorized the construction,

with private capital, of a lock and dam at Hales Bar to provide a channel 6ft. deep between it and Chattanooga, the water-power to be used by the company furnishing the capital The Colbert and Bee Tree shoals were improved by the Colbert Shoals lock and canal, opened in 1911. In 1917 the U.S. Government undertook the construction of a navigation power dam (Wilson or dam No 2), 95ft high at Muscle shoals (*q.v.*) and by 1926 the work had been completed, except the lock, at a cost of $43,387,709 for construction and $359,592 for maintenance. A second lock and dam (known as No. 1), below Wilson dam, was completed and put in operation in March 1926, at a cost of $960,515 The Federal Government had spent, up to 1927, about $30,000,000, exclusive of the Muscle Shoals dams, on improving navigation on the Tennessee and its tributaries. The total commerce carried on the various sections of the Tennessee had, in 1925, an aggregate value of $12,441,364; the commerce of its principal tributaries amounted to $142,959

TENNGLER, ULRICH, German jurist, was born in the middle of the 15th century in Heidenheim near Nordlingen. He served as chief clerk of Nördlingen, 1479–83, and afterwards, until his death, was governor of Hochstadt He died sometime in the first four months of 1511. He is noted chiefly as the author of the *Layenspiegal* (1509 and later editions After 1516 the work was frequently issued in editions containing also Sebastian Brant's *Klagspiegal*). This was a systematic encyclopaedia of popular jurisprudence, which had wide influence and for more than half a century was the authority in Germany for the settlement of legal questions.

TENNIEL, SIR JOHN (1820–1914), knighted 1893, English humorous and satirical artist—specially identified with *Punch* —was born in London on Feb 28, 1820 Although he became a probationer, and then a student, of the Royal Academy, he soon left the schools, where at that time there was little teaching. In 1836 he sent his first picture to the exhibition of the Society of British Artists, and in 1845 contributed a 16-ft. cartoon, "An Allegory of Justice," to the competition, held in that year, of designs for the mural decoration of the new Palace of Westminster. For this he received a £200 premium and a commission to paint a fresco in the Upper Waiting Hall (or "Hall of Poets") in the House of Lords. He was already known and appreciated as a humorist, and his early companionship with Charles Keene fostered and developed his talent for scholarly caricature. In 1850 he was invited by Mark Lemon to fill the position of joint cartoonist (with John Leech) on *Punch,* in succession to Richard Doyle. His first "cartoon" was "Lord Jack the Giant Killer", it showed Lord John Russell, whose letter on the "aggression" had recently been published, valiantly assailing with the sword of truth and liberty Cardinal Wiseman armed with a crozier. In 1852 we find Tenniel's first superb lion, and his first obituary cartoon. Gradually he took over altogether the weekly drawing of the political "big cut," which John Leech was happy to resign into his hands in order to restrict himself to his pictures of life and character Leech's work consisted for the most part of farce; Tenniel's was high comedy, and not infrequently tragedy, and the freedom of the humorist heightened the severer beauties of the satirist When Leech died his friend continued his work alone. About 2,300 cartoons, innumerable minor drawings, double-page cartoons for *Punch's Almanac* and other special numbers, and 250 designs for *Punch's Pocket-books,* comprise the sum of Sir John Tenniel's work for the periodical in the service of which he spent the greater portion of his life. He retired in 1901. In 1874 he had been made a member of the Royal Institute of Painters in Water Colours. He died on Feb. 25, 1914.

The main quality of Sir John Tenniel's work is accuracy of drawing, precision of touch, grace and dignity of conception, and —so far as such things can be compatible—geniality of satire. Tenniel raised the political cartoon into a classic composition, from which a sense of nobility is rarely absent. The beauty and statuesqueness of his ideal figures recall the influence, perhaps, of Cornelius and Overbeck—that German manner which was characteristic of many of our finer draughtsmen upon wood in the middle of the 19th century. But Tenniel's work is always original, unforced and fresh; and it never suggests, what is the fact, that the artist's work is drawn exclusively from memory, and never from the model. It may be mentioned that Tenniel's wonderful observation has been conducted, and his knowledge accumulated, literally through a single eye, the other having been lost during a fencing bout in his youth. It was in recognition not only of his ability as an artist in black and white, but of his service in infusing good humour and good taste into one phase of political life, that a knighthood was conferred upon him on Mr. Gladstone's recommendation in 1893. Without pronounced political opinions of his own, Sir John Tenniel adopted in his work those of his paper, of which the Whig proclivities were to some degree softened by his pencil. The political history not of England only, but to some extent of the world, of half a century appears in Sir John Tenniel's weekly cartoons, which are dignified by a number of types invented by the artist, the classic beauty of which may be looked for in vain in kindred work by any previous cartoonist. (Take, for example, Sir John's famous picture of "Dropping the Pilot," which appeared in *Punch* on March 20, 1890, xcviii. 150–51.) Public exhibitions of Sir John Tenniel's work were held in 1895 and in 1900. Sir John Tenniel is also the author of one of the mosaics, "Leonardo da Vinci," in the South Court in the Victoria and Albert Museum, while his highly stippled water-colour drawings appeared from time to time in the exhibitions of the Royal Institute of Painters in Water Colours, of which society he was elected a member in 1874 As an illustrator on the wood-block he stands very high; his "Lalla Rookh" is perhaps the finest of all his work in point of conception, refinement, power and technical excellence

WORKS ILLUSTRATED.—(1) *Juvenile Verse and Picture Book* (1846); (2) *Undine* (1846), (3) *Aesop's Fables,* 100 drawings (1848), (4) Blair's *Grave* (1858); (5) Shirley Brooks's *The Gordian Knot* (1860), and (6) *The Silver Cord* (1861); (7) Moore's *Lalla Rookh,* 69 drawings (1861); (8) Lewis Carroll's *Alice's Adventures in Wonderland* (1866), (9) *The Mirage of Life* (1867); (10) Carroll's *Through the Looking-Glass* (1870); and the following in collaboration (11) Pollok's *Course of Time* (1857); (12) *Poets of the Nineteenth Century* (1857), (13) Poe's Works (1857), (14) *Home Affections* (1858), (15) Cholmondeley Pennell's *Puck on Pegasus* (1863); (16) *The Arabian Nights* (1863), (17) *English Sacred Poetry* (1864), (18) *Legends and Lyrics* (1865), (19) Tupper's *Proverbial Philosophy;* (20) Barry Cornwall's *Poems,* and other books. He also contributed to *Once a Week,* the Art Union publications, etc. *See* also *Cartoons by Sir John Tenniel* (1901), M H Spielmann, *History of Punch* (1895); Cosmo Monkhouse, *Life and Works of Sir John Tenniel* (*Art Annual,* 1901).

TENNIS: *see* LAWN TENNIS AND TENNIS.

TENNON, in architecture, a projecting tooth, peg or lug, cut upon the end or edge of a structural member, and arranged to fit into a socket or mortice designed to receive it in an adjacent structural member, in order to strengthen and stiffen the connection between them.

TENNYSON, ALFRED TENNYSON, 1st BARON (1809–1892), English poet, was born at Somersby, Lincolnshire, on Aug. 6, 1809 He was the fourth of the 12 children of the Rev. George Clayton Tennyson (1778–1831) and his wife Elizabeth Fytche (1781–1865). The Tennysons were an old Lincolnshire family settled at Bayon's Manor. The poet's grandfather, George Tennyson, M.P , had disinherited the poet's father, who was settled hard by in the rectory of Somersby, in favour of the younger son, Charles Tennyson D'Eyncourt. The rich pastoral scenery of this part of Lincolnshire influenced the imagination of the boy, and is plainly reflected in all his early poetry. At a very early age he began to write in prose and verse. At Christmas 1815 he was sent to the grammar school at Louth, where he remained for five years, and then returned to Somersby to be trained by his father In the rectory the boys had the run of an excellent library, and here the young poet based his wide knowledge of the English classics. The news of Byron's death (April 19, 1824) made a deep impression on him. "It was a day," he said, "when the whole world seemed to be darkened for me"; he went out into the woods and carved "Byron is dead" upon a rock. Tennyson was already writing copiously—he had constructed "an epic of 6,000 lines" at the age of twelve, composed a drama in blank verse when he was 14, and so on.

In 1827 Frederick Tennyson (1807–1898), the eldest surviving brother, uniting with his younger brothers Charles and Alfred, published at Louth an anonymous collection of *Poems by Two Brothers*. The "two" were Charles and Alfred (whose contributions predominated), and who shared the surprising profits, £20. On Feb. 20, 1828, Charles and Alfred matriculated at Trinity college, Cambridge, where Frederick was already a student. The poet subsequently told Edmund Gosse that his father would not let him leave Somersby till, on successive days, he had recited from memory the whole of the odes of Horace. The brothers took rooms at 12 Rose Crescent, and afterwards moved into Trumpington Street (now 157 Corpus Buildings). They were shy, and at first made few friends; but they gradually gathered selected associates around them, and Alfred grew to be looked up to in Cambridge "as to a great poet and an elder brother" by a group which included Richard Chenevix Trench, Monckton Milnes (Lord Houghton), James Spedding, W. H. Thompson, Edward FitzGerald, W. H. Brookfield, and, above all, A. H. Hallam (1811–1833). Charles Tennyson (1808–1879) afterwards took the additional name of Turner. He published four volumes of sonnets which have been highly praised. In June 1829 Alfred Tennyson won the Chancellor's prize medal for his poem called "Timbuctoo." With great imperfections, this study in Miltonic blank verse displays the genius of a poet, in spite of obscurity both of thought and style. Here are already both richness and power. But by this time Tennyson was writing lyrics of still higher promise, and, as Arthur Hallam early perceived, with an extraordinary earnestness in the worship of beauty. The results of this enthusiasm and this labour of the artist appeared in the volume of *Poems, chiefly Lyrical*, published in 1830. This book would have been astonishing as the production of a youth of 21, even if, since the death of Byron six years before, there had not been a singular dearth of good poetry in England. Here at least. in the slender volume of 1830, was a new writer revealed, and in "Mariana," "The Poet," "Love and Death," and "Oriana," a singer of wonderful though still unchastened melody. Through these, and through less perfect examples, was exhibited an amazing magnificence of fancy, at present insufficiently under control, and a voluptuous pomp of imagery, tending to an over-sweetness.

In the summer of 1830 Tennyson and Hallam volunteered in the army of the Spanish insurgent Torrijos, and marched about a little in the Pyrenees, without meeting with an enemy. Tennyson came back to find his father ailing, and in Feb. 1831 he left Cambridge for Somersby, where a few days later Dr. George Tennyson died. The new incumbent was willing that the Tennysons should continue to live in the rectory, which they did not leave until six years later. Arthur Hallam was now betrothed to Emily Tennyson (afterwards Mrs. Jesse, 1811–1889), and stayed frequently at Somersby. This was a very happy time, and one of great physical development on Alfred's part. He took his share in all kinds of athletic exercises, and it was now that Brookfield said, "It is not fair that you should be Hercules as well as Apollo." This high physical zest in life seems to have declined after 1831, when his eyes began to trouble him, and he became liable to depression. The poetical work of these three years, mainly spent at Somersby, was given to the world in the volume of *Poems* which (dated 1833) appeared at the end of 1832.

This was certainly one of the most astonishing revelations of finished genius ever produced by a young man of less than four-and-twenty. Here were "The Lady of Shalott," "The Dream of Fair Woman," "Oenone," "The Lotos-Eaters," "The Palace of Art," and "The Miller's Daughter," with a score of other lyrics, delicious and divine. The advance in craftsmanship and command over the *matériel* of verse shown since the volume of 1830 is astonishing. It was well that its publication was completed before the blow fell upon Tennyson which took for a while all the light out of him. In Aug. 1833 Arthur Hallam started with his father, the historian, for Tirol. On the way young Hallam died suddenly (Sept. 15) of a broken blood-vessel at Vienna. His body was brought back to England, and buried on Jan. 3, 1834.

Hallam's death affected Tennyson extremely. He grew less than ever willing to come forward and face the world; his health became "variable and his spirits indifferent." The earliest effect of Hallam's death upon his friend's art was seen, in the summer of 1834, in *The Two Voices;* and to the same period belong the beginnings of the *Idylls of the King* and of *In Memoriam*, over both of which he meditated long. In 1835 he visited the Lakes, and saw much of Hartley Coleridge, but would not "obtrude on the great man at Rydal," although "Wordsworth was hospitably disposed." Careless alike of fame and of influence, Tennyson spent these years mainly at Somersby, in a uniform devotion of his whole soul to the art of poetry. In 1837, to their great distress, the Tennysons were turned out of the Lincolnshire rectory where they had lived so long. They moved to High Beech, in Epping Forest, which was their home until 1840. The poet was already engaged, or "quasi-betrothed," to Emily Sellwood, but ten years passed before they could afford to marry. At Torquay, in 1838, he wrote *Audley Court* on one of his rare excursions, for he had no money for touring, nor did he wish for change; he wrote at this time, "I require quiet, and myself to myself, more than any man when I write." In 1840 the Tennysons moved to Tunbridge Wells, and a year later to Boxley, near Maidstone, to be close to Edmund Lushington, who had now married Cecilia Tennyson. Alfred was from this time frequently a visitor in London.

In 1842 the two-volume edition of his *Poems* broke the ten years' silence which he had enforced himself to keep. Here, with many pieces already known to all lovers of modern verse, were found rich and copious additions to his work. These he had originally intended to publish alone, and an earlier privately printed *Morte d'Arthur, Dora, and other Idylls*, of 1842, is the despair of book-collectors. Most of those studies of home-life in England, which formed so highly popular a section of Tennyson's work—such as "The Gardener's Daughter," "Walking to the Mail," and "The Lord of Burleigh"—were now first issued, and, in what we have grown to consider a much higher order, "Locksley Hall," "Ulysses," and "Sir Galahad." To the older and more luxurious lyrics, as reprinted in 1842, Tennyson did not spare the curbing and pruning hand, and in some cases went too far in restraining the wanton spirit of beauty in its youthful impulse. It is from 1842 that Tennyson took his place as the leading poet of his age in England. Among the friends whom he now made, or for the first time cultivated, were Carlyle, Rogers, Dickens, and Elizabeth Barrett.

Material difficulties now, however, for the first time intruded on Tennyson's path. He became the victim of a certain "earnest-frothy" speculator, who induced him to sell his little Lincolnshire estate at Grasby, and to invest the proceeds, with all his other money, and part of that of his brothers and sisters, in a "Patent Decorative Carving Company"; in a few months the whole scheme collapsed, and Tennyson was left penniless. He was attacked by so overwhelming a hypochondria that his life was despaired of, and he was placed for some time under the charge of a hydropathic physician at Cheltenham, where absolute rest and isolation gradually brought him round to health again. The state of utter indigence to which Tennyson was reduced greatly exercised his friends, and in Sept. 1845, at the suggestion of Henry Hallam, Sir Robert Peel was induced to bestow on the poet a pension of £200 a year. Tennyson's health slowly became restored, and in 1846 he was hard at work on *The Princess;* in the autumn of this year he took a tour in Switzerland, and saw great mountains and such "stateliest bits of landskip" for the first time. In 1847 nervous prostration again obliged him to undergo treatment at Prestbury: "They tell me not to read, not to think; but they might as well tell me not to live." Dr. Gully's water-cure was tried, with success.

The Princess was now published, in a form afterwards considerably modified and added to. Carlyle and FitzGerald "gave up all hopes of him after *The Princess*," or pretended that they did. It was true that the bent of his genius was slightly altered, in a direction which seemed less purely and austerely that of the highest art; but his concessions to public taste vastly added to the width of the circle he now addressed. The home of the Tennysons was now at Cheltenham; on his occasional visits to London he was in the habit of seeing Thackeray, Coventry Pat-

more, Browning and Macready, as well as older friends, but he avoided "society." In 1848, while making a tour in Cornwall, Tennyson met Robert Stephen Hawker of Morwenstow, with whom he seems—but the evidence is uncertain—to have talked about King Arthur, and to have resumed his intention of writing an epic on that theme.

In his absent-minded way Tennyson was very apt to mislay objects; in earlier life he had lost the ms. of *Poems, chiefly Lyrical,* and had been obliged to restore the whole from scraps and memory. Now a worse thing befell him, for in February 1850, having collected into one "long ledger-like book" all the elegies (*In Memoriam*) on Arthur Hallam which he had been composing at intervals since 1833, he left this only ms. in the cupboard of some lodgings in Mornington Place, Hampstead Road By extraordinary good chance it had been overlooked by the landlady, and Coventry Patmore was able to recover it *In Memoriam* was published, in its original anonymous form, in May 1850 The public was at first greatly mystified by the nature and object of this poem, which was not merely a chronicle of Tennyson's emotions under bereavement, nor even a statement of his philosophical and religious beliefs, but, as he long afterwards explained, a sort of *Divina Commedia,* ending with happiness in the marriage of his youngest sister, Cecilia Lushington. In fact, the great blemishes of *In Memoriam,* its redundancy and the dislocation of its parts, were largely due to the desultory manner of its composition The poet wrote the sections as they occurred to him, and did not think of weaving them together into a single poem until it was too late to give them real coherency.

On June 13, 1850, Tennyson was married at Shiplake to Emily Sarah Sellwood (1813–1896). Of this union no more need be said than was recorded long afterwards by the poet himself, "The peace of God came into my life before the altar when I wedded her" On Nov 19, 1850, Queen Victoria appointed Tennyson poet laureate, in succession to Wordsworth The salary connected with the post was very small, but it had a secondary value in stimulating the sale of his books. The young couple took a house at Warninglid, in Sussex, which did not suit them, and then one in Montpelier Row, Twickenham, which did better In April 1851 their first child was born dead At this time Tennyson was brooding much upon the ancient world, and reading little but Milton, Homer and Virgil This condition was elegantly defined by Carlyle as "sitting on a dungheap among innumerable dead dogs" In the summer of 1851 was made the tour in Italy, of which *The Daisy* is the immortal record. Of 1852 the principal events were the birth of his eldest son Hallam, the second Lord Tennyson, in August, and in November the publication of the *Ode on the Death of the Duke of Wellington.*

In the winter of 1853 Tennyson took a little house and farm called Farringford, near Freshwater, in the Isle of Wight, which he leased at first, and afterwards bought, this beautiful place, ringed round with ilexes and cedars, entered into his life and coloured it with its delicate enchantment. In 1854 he published *The Charge of the Light Brigade,* and was busy composing *Maud* and its accompanying lyrics; and this volume was published in July 1855, just after he was made D.C.L. at Oxford: he was received on this occasion, which may be considered his first public appearance, with a "tremendous ovation." The reception of *Maud* from the critics, however, was the worst trial to his equanimity which Tennyson had ever had to endure, nor had the future anything like it in store for him. He had risen in *Maud* far above his ordinary serenity of style, to ecstasies of passion and audacities of expression which were scarcely intelligible to his readers

It is odd that this irregular poem, with its copious and varied music, its splendid sweep of emotion, its unfailing richness of texture—this poem in which Tennyson rises to heights of human sympathy and intuition which he reached nowhere else, should have been received with bitter hostility, have been styled "the dead level of prose run mad," and have been reproved more absurdly still for its "rampant and rabid bloodthirstiness of soul." There came a reaction of taste and sense, but the delicate spirit of Tennyson had been wounded. For some years the world heard nothing from him; he was at Farringford, busying himself with the Arthurian traditions. He had now become an object of boundless personal curiosity, being already difficult to find, and the centre of amusing legends It was in 1857 that Bayard Taylor saw him, and carried away the impression of a man "tall and broad-shouldered as a son of Anak, with hair, beard and eyes of southern darkness." This period of retirement embraced a tour in Wales in 1857, a visit to Norway in 1858, and a journey through Portugal in 1859.

In 1857 two Arthurian poems had been tentatively and privately printed, as *Enid and Nimue, or the True and the False,* to see how the idyllic form would be liked by the inner circle of Tennyson's friends. In the summer of 1859 the first series of *Idylls of the King* was at length published, and achieved a popular success far beyond anything experienced before by any English poets, save perhaps Byron and Scott. Within a month of publication, 10,000 copies had been sold The idylls were four in number, "Enid," "Vivien" (no longer called "Nimue"), "Elaine" and "Guinevere" These were fragments of the epic of the fall of King Arthur and the Table Round which Tennyson was so long preparing, and which he can hardly be said to have ever completed, although nearly thirty years later he closed it. The public and the critics alike were entranced with the "sweetness" and the "purity" of the treatment. A few, like Ruskin, were doubtful about "that increased quietness of style", one or two already suspected that the "sweetness" was obtained at some sacrifice of force, and that the "purity" involved a concession to Victorian conventionality.

Urged by the duke of Argyll, Tennyson now turned his attention to the theme of the Holy Grail, though he progressed with it but fitfully and slowly In 1861 he travelled in Auvergne and the Pyrenees, with Clough, who was to die a few months later; to this year belong "Helen's Tower" and the "Dedication" of the *Idylls* to the prince consort, "These to his Memory." The latter led to Tennyson's presentation in April 1862 to the queen, who "stood pale and statue-like before him, in a kind of stately innocence," which greatly moved his admiring homage From this time forth the poet enjoyed the constant favour of the sovereign, though he could never be moulded into a conventional courtier. He now put the Arthurian legends aside for a time, and devoted himself to the composition, in 1862, of "Enoch Arden," which, however, did not appear until 1864, and then in a volume which also contained "Sea Dreams," "Aylmer's Field" and, above all, "The Northern Farmer," the first and finest of Tennyson's remarkable studies in dialect.

In April of this year Garibaldi visited Farringford; in Feb. 1865 Tennyson's mother died at Hampstead in her 85th year; in the ensuing summer he travelled in Germany. The time slipped by with incidents but few and slight, Tennyson's popularity in Great Britain growing all the time to an extent unparalleled in the whole annals of English poetry. This universality of fame led to considerable practical discomfort; he was besieged by sightseers, and his nervous trepidation led him perhaps to exaggerate the intensity of the infliction. In 1867 he determined to make for himself a haven of refuge against the invading Philistine, and bought some land on Blackdown, above Haslemere, then a secluded corner of England; here Mr. (afterwards Sir) James Knowles began to build him a house, ultimately named Aldworth. This is the time of two of his rare, privately printed pamphlets, *The Window; or, the Loves of the Wrens* (1867), and *The Victim* (1868).

The noble poem *Lucretius,* one of the greatest of Tennyson's versified monographs, appeared in May 1868, and in this year *The Holy Grail* was at last finished; it was published in 1869. together with three other idylls belonging to the Arthurian epic, and various miscellaneous lyrics, besides *Lucretius.* The reception of this volume was cordial, but not so universally respectful as that which Tennyson had grown to expect from his adoring public. The fact was that the heightened reputation of Browning, and still more the sudden vogue of Swinburne, Morris and Rossetti (1866–70), considerably disturbed the minds of Tennyson's most ardent readers, and exposed himself to a severer criticism than he had lately been accustomed to endure. His next volume (1872), *Gareth and Lynette* and *The Last Tournament,* continued, and,

as he then supposed, concluded *The Idylls of the King,* and for the time being he dismissed it from his mind. In 1873 he was offered a baronetcy by Gladstone, and again by Disraeli in 1874; in each case the honour was gracefully declined.

Believing that his work with the romantic Arthurian epics was concluded, Tennyson now turned his attention to the drama. He put before him a scheme of illustrating "the making of England" by a series of great historical tragedies. His *Queen Mary,* the first of these chronicle-plays was published in 1875, and played by Sir Henry Irving at the Lyceum in 1876. Although it was full of admirably dramatic writing, it failed on the stage. Extremely pertinacious in this respect, the poet went on attempting to storm the theatre, with assault upon assault, all practically failures until the seventh and last, which was unfortunately posthumous. Meanwhile *Harold,* a tragedy of doom, was published in 1876; but, though perhaps the finest of its author's dramas, it was not staged. During these years Tennyson's thoughts were largely occupied with the building of Aldworth. His few lyrics were spirited ballads of adventure, inspired by an exalted patriotism—"The Revenge" (1878), "The Defence of Lucknow" (1879)—but he reprinted and finally published his old suppressed poem, *The Lover's Tale,* and a little play of his, *The Falcon,* versified out of Boccaccio, was produced by the Kendals in 1879.

In 1880, when he was over 70, he published the earliest of six important collections of lyrics, this being entitled *Ballads and other Poems,* and containing the sombre and magnificent "Rizpah." In 1881 *The Cup* and in 1882 *The Promise of May,* two little plays, were produced without substantial success in London theatres: the second of these is perhaps the least successful of all the poet's longer writings, but its failure annoyed him unreasonably. In September 1883 Tennyson and Gladstone set out on a voyage round the north of Scotland, to Orkney, and across the ocean to Norway and Denmark. At Copenhagen they were entertained by the king and queen, and after much fêting, returned to Gravesend: this adventure served to cheer the poet, who had been in low spirits since the death of his favourite brother Charles, and who now renewed his vigour. During the voyage Gladstone had determined to offer Tennyson a peerage. After some demur, the poet consented to accept it, but added, "For my own part, I shall regret my simple name all my life." On March 11, 1884, he took his seat in the House of Lords as Baron Tennyson of Aldworth and Farringford. He voted twice, but never spoke in the House. In the autumn of this year his tragedy of *Becket* was published, but the poet at last despaired of the stage, and disclaimed any hope of "meeting the exigencies of our modern theatre." Curiously enough, after his death *Becket* was the one of all his plays which enjoyed a great success on the boards.

In 1885 was published another interesting miscellany, *Tiresias and other Poems,* with a posthumous dedication to Edward FitzGerald. In this volume, it should be noted, *The Idylls of the King* was completed at last by the publication of "Balin and Balan"; it contained also the superb address "To Virgil." In April 1886 Tennyson suffered the loss of his second son, Lionel, who died in the Red Sea on his return from India. The untiring old poet was steadily writing on, and by 1886 he had another collection of lyrics ready, *Locksley Hall Sixty Years After,* etc.; his eyes troubled him, but his memory and his intellectual curiosity were as vivid as ever. He was past 80 when he published the collection of new verses entitled *Demeter and other Poems* (1889), which appeared almost simultaneously with the death of Browning, an event which left Tennyson a solitary figure indeed in poetic literature. His latest drama, *The Foresters,* was produced in New York in March 1892, with Miss Ada Rehan as Maid Marian. During this year Tennyson was steadily engaged on "Akbar's Dream," "Kapiolani" and other contents of the posthumous volume called *The Death of Oenone,* 1892.

Soon after entering his eighty-fourth year, however, symptoms of weakness set in, and early in September his condition began to give alarm. He retained his intellectual lucidity and an absolute command of his faculties to the last, reading Shakespeare with obvious appreciation until within a few hours of his death. With the splendour of the full moon falling upon him, his hand clasping his Shakespeare, and looking, as we are told, almost unearthly in the majestic beauty of his old age, Tennyson passed away at Aldworth on the night of Oct. 6, 1892. *Cymbeline,* the play he had been reading on the last afternoon, was laid in his coffin, and on the 12th he received a public funeral at Westminster Abbey. Lady Tennyson survived until Aug. 1896.

The physical appearance of Tennyson was very remarkable. Of his figure at the age of 33 Carlyle has left a superb portrait: "One of the finest-looking men in the world. A great shock of rough, dusky, dark hair; bright, laughing, hazel eyes; massive aquiline face, most massive yet most delicate; of sallow brown complexion, almost Indian-looking, clothes cynically loose, free-and-easy, smokes infinite tobacco. His voice is musical, metallic, fit for loud laughter and piercing wail, and all that may lie between; speech and speculation free and plenteous; I do not meet in these late decades such company over a pipe." He was unusually tall, and possessed in advanced years a strange and rather terrifying air of sombre majesty. But he was, in fact, of a great simplicity in temperament, affectionate, shy, still exquisitely sensitive in extreme old age to the influences of beauty, melancholy and sweetness. Although exceedingly near-sighted, Tennyson was a very close observer of nature, and at the age of eighty his dark and glowing eyes, which were still strong, continued to permit him to enjoy the delicate features of country life around him, both at Aldworth and in the Isle of Wight. His *Life,* written with admirable piety and taste by his son, Hallam, second Lord Tennyson, was published in two volumes in 1897.

No living poet has ever held England—no poet but Victor Hugo has probably ever held any country—quite so long under his unbroken sway as Tennyson did. As he recedes from us, however, we begin to see that he has a much closer relation to the great Georgian writers than we used to be willing to admit. He is more the last of that great school than the first of any new one. The qualities in which he seems to surpass his immediate predecessors are exactly those which should be the gift of one who sums up the labours of a mighty line of artists. He is remarkable among them for the breadth, the richness, the substantial accomplishment of his touch; he has something of all these his elders, and goes farther along the road of technical perfection than any of them. We still look to the earlier masters for supreme excellence in particular directions: to Wordsworth for sublime philosophy, to Coleridge for ethereal magic, to Byron for passion, to Shelley for lyric intensity, to Keats for richness.

Tennyson does not excel each of these in his own special field, but he is often nearer to the particular man in his particular mastery than any one else can be said to be, and he has in addition his own field of supremacy. This consists, perhaps, in the beauty of the atmosphere which Tennyson contrives to cast around his work, moulding it in the blue mystery of twilight, in the opaline haze of sunset: this atmosphere, produces an almost unfailing illusion or mirage of loveliness, so that, even where (as must sometimes be the case with every poet) the thought and the imagery have little value in themselves, the fictive aura of beauty broods over the otherwise undistinguished verse. In his luminous subtlety and his broad undulating sweetness, his relationship with Virgil has long been manifest; he was himself aware of it. But he was also conscious that his exquisite devotion to mere lucidity and beauty might be a snare to him, and a happy instinct was always driving him to a study of mankind as well as of inanimate nature.

Few English writers have known so adroitly as Tennyson how to bend the study of Shakespeare to the enrichment of their personal style. It should be added that he was a very deep and original student of literature of every description, and that the comparatively few specimens which have been preserved of his conversation contain some of the finest fragments of modern appreciation of the great poets which we possess. This is worthy of consideration in any attempt made to sketch the mind of a man who was above all other masters of recent literature an artist, and who must be studied in the vast and orbic fullness of his accomplishment in order to be appreciated at all. (E. G.)

The standard biography is *Alfred, Lord Tennyson: A Memoir,* by

Hallam, 2nd Baron Tennyson (2 vols., 1897), who also edited Tennyson's *Works* with a memoir in 1913 (9 vols); A. E. Baker published a *Concordance to the poetical and dramatical works of Tennyson* in 1914. For bibliography *see* R. H Shepherd, *Tennysoniana* (1866, new ed 1879) For biography and criticism consult A C. Bradley, *A Commentary on Tennyson's In Memoriam* (1901); A. Lang, *Alfred Tennyson* (1901); A C. Benson, *The Life of Lord Tennyson* (1904); T R Lownsbury, *Life and Times of Lord Tennyson* (1916), H. I 'A. Fausset, *Tennyson; A modern portrait* (1923), H. Nicolson, *Tennyson* (1925).

TENNYSON-D'EYNCOURT, SIR EUSTACE (HENRY WILLIAM) (1868–), British naval architect, was born on April 1, 1868, and educated at Charterhouse and at the Royal Naval college, Greenwich He was apprenticed at the Elswick works, to which he returned as naval architect in 1902, after four years at Fairfield. He subsequently received an Admiralty appointment, which he held until 1924. He continued to advise the Admiralty on naval construction after his appointment as managing director of Armstrong Whitworth and Co's Newcastle shipyards In addition to designing and constructing ships, Tennyson-d'Eyncourt was closely associated with the development of tanks during the World War He presided over the first Admiralty committee on the question, and in 1918 became vice-president of the Tank board He was responsible for the successful design and construction of many tanks. He was created K C B in 1917, and elected F R S. in 1921.

TENREC (*Centetes ecaudatus*), one of the largest representatives of the Insectivora, the length being from 12 to 16in. It is restricted to Madagascar. The coat consists chiefly of bristles and hairs, with an admixture of flexible spines, in the adult limited to the back of the neck The general hue is brown tinged with yellow. From 12 to 16 or even 20 young are produced at a birth. In habits the tenrec is nocturnal, its home is in the brush in the mountain regions, and in the cool season it hibernates in deep burrows. The long flexible snout is used to root up worms and grubs, and ground-insects form part of its nourishment When fat before hibernation, tenrecs are much valued as food by natives (*See* INSECTIVORA.)

TENSOR ANALYSIS. The concept of tensors and the knowledge of some of their properties can be traced back to Gauss, Riemann and Christoffel, but their algebra and analysis have been shaped into a systematic method only recently, 1900, by Ricci and Levi-Civita, who coined for this powerful branch of mathematics the name of *absolute differential calculus.* Its chief aim is to construct and discuss relations or laws *generally covariant;* such, that is, as remain valid in passing from one to any other system of co-ordinates. It has especially become the object of a very widespread interest since the advent of *generalized relativity* (1916), whose principal requirement is precisely such unrestricted covariance of physical laws.

Definitions, Algebra of Tensors.—Consider a continuous n-dimensional manifold or "space" S_n (*see* MANIFOLDS), whose element or point $P(x_\iota)$ is determined by assigning the values of n real independent variables or co-ordinates x_ι Let $Q(x_\iota+dx_\iota)$ be another point of S_n. Then the ordered point-pair P, Q or the set of differentials dx_ι is called a *vector.* (To begin with, the idea of "size" or "length" is foreign to this concept, S_n being thus far a non-metrical manifold.) Let the x_ι be transformed into any other system of n co-ordinates x'_ι, the former being continuous functions of the latter with continuous derivatives $\partial x_\iota/\partial x'_\kappa$ and non-vanishing, finite Jacobian $J=\left|\frac{\partial x_\iota}{\partial x'_\kappa}\right|$; then dx_ι are transformed into

$$dx'_\iota=\frac{\partial x'_\iota}{\partial x_\alpha}\,dx_\alpha$$

to be summed over $\alpha=1$ to n, and vice versa, $dx_\iota=(\partial x_\iota/\partial x'_\alpha)dx'_\alpha$. (The convention will be adopted that every term in which an index occurs *twice*, is to be summed over all its values.) Any set of n magnitudes A^ι, functions of the x, which are transformed by this rule, *i.e.*, into

$$A'^\iota=\frac{\partial x'_\iota}{\partial x_\alpha}\,A^\alpha,$$

is called a *contravariant tensor* of rank one, the A^ι being its n^1 *components.* For contravariant tensors upper indices are used, an exception being made for dx_ι, the prototype of all such tensors. Next, any n magnitudes A_ι which are transformed as the differentiators $\partial/\partial x_\iota$, *i.e.*, into

$$A'_\iota=\frac{\partial x_\alpha}{\partial x'_\iota}\,A_\alpha,$$

form a *covariant* tensor of rank 1, lower indices being used for such tensors. These two kinds of tensors, of rank 1, are also termed *vectors, e.g.*, three-vectors, four-vectors (such as the relativistic four-velocity or four-potential, in space-time, S_4), etc., according as $n=3$, 4, etc. Similarly, any n^2 magnitudes $A_{\iota\kappa}$ transformable into

$$A'_{\iota\kappa}=\frac{\partial x_\alpha}{\partial x'_\iota}\,\frac{\partial x_\beta}{\partial x'_\kappa}\,A_{\alpha\beta}$$

form a covariant, and any $A^{\iota\kappa}$ transformable into

$$A'^{\iota\kappa}=\frac{\partial x'_\iota}{\partial x_\alpha}\,\frac{\partial x'_\kappa}{\partial x_\beta}\,A^{\alpha\beta}$$

form a contravariant tensor of *rank two.* Again, n^2 magnitudes A_ι^κ transformable into

$$A'^{\kappa}_\iota=\frac{\partial x_\alpha}{\partial x'_\iota}\,\frac{\partial x'_\kappa}{\partial x_\beta}\,A^\beta{}_\alpha$$

are said to form a *mixed* tensor of rank 2, covariant in ι and contravariant in κ. The extension to any rank is obvious. Any $n^{r_1+r_2}$ magnitudes $A^{ik}_{\iota\kappa}$, with r_1 lower and r_2 upper indices, which are transformed according to the rule

$$\left(A^{ik\cdots}_{\iota\kappa\cdots}\right)'=\frac{\partial x_\alpha}{\partial x'_\iota}\,\frac{\partial x_\beta}{\partial x'_\kappa}\cdots\frac{\partial x'_i}{\partial x_a}\,\frac{\partial x'_k}{\partial x_b}\cdots A^{ab\cdots}_{\alpha\beta\cdots} \qquad (1)$$

form a mixed tensor of rank $r=r_1+r_2$ This is the most general concept of a tensor.

A tensor of rank zero, called also a *scalar,* is a single function of the x, *invariant* with respect to any transformations of co-ordinates, $f'=f$. $A_{\iota\kappa}$ is *symmetrical* if $A_{\iota\kappa}=A_{\kappa\iota}$, and *antisymmetrical* or a *skew* tensor if $A_{\iota\kappa}=-A_{\kappa\iota}$, implying $A_{\iota\iota}=0$. Similarly for $A^{\iota\kappa}$. Analogous definitions hold for mixed tensors, and for higher ranks Symmetry and antisymmetry are invariant properties.

The transformed tensor components being linear homogeneous functions of the original ones, the sums of corresponding components of tensors of same rank and kind form again a tensor. Thus, A_ι, B_ι being covariant vectors, so is $A_\iota+B_\iota=C_\iota$. Similarly, $A_{\iota\kappa}+B_{\iota\kappa}=C_{\iota\kappa}$, etc. The addends, functions of x_ι, must be taken at the same point of S_n. If a tensor vanishes in one, it will vanish also in any other co-ordinate system. Consequently, any tensor equation, if valid in one, holds also in any other co-ordinate system. This is the chief reason of the importance of tensors in pure geometry and relativistic physics

The *outer product* of two tensors of ranks r and s, *i.e*, the array of n^{r+s} products of their components is again a tensor, of rank $r+s$, with r_1+s_1 covariant and r_2+s_2 contravariant indices. Thus $A_\iota B_\kappa=C_{\iota\kappa}$, $A_{\iota\kappa}B_\lambda=C_{\iota\kappa\lambda}$, $A_{\iota\kappa}B^\lambda=C^\lambda{}_{\iota\kappa}$. The *contraction,* an operation of almost magical efficiency, applicable to any mixed tensor, consists in equating one of its r_1 lower to one of its r_2 upper indices and summing over it from 1 to n. The result is again a tensor, with r_1-1 covariant and r_2-1 contravariant indices, *e.g.*, the contraction of $A^\lambda_{\iota\kappa}$ gives $A^\kappa{}_{\iota\kappa}=A_\iota$, a vector; $B^{\lambda\mu}_{\iota\kappa}$ contracted once becomes $B^{\lambda\kappa}_{\iota\kappa}=B^\lambda{}_\iota$, and this yields $B^\iota{}_\iota=B$, a scalar.

The *inner product* is the outer product (supposed mixed) contracted once or more. Thus, the inner product of A_ι, B^κ is $A_\kappa B^\kappa$, an invariant; that of $A_{\iota\kappa}$, $B^{\lambda\mu}$ gives $A_{\iota\kappa}B^{\lambda\kappa}=C^\lambda{}_\iota$, a mixed tensor, and, after a second contraction, $A_{\iota\kappa}B^{\iota\kappa}=C^\iota{}_\iota=C$, an invariant. (Unlike $A_\kappa B^\kappa$, $A_\kappa B_\kappa$ is *not* invariant; it has no tensor character, and likewise for $A^\kappa B^\kappa$. Thus also $A_{\iota\kappa}$, unlike $A^\kappa{}_\iota$, has no invariant of its own.) Again, the inner product of $A_{\iota\kappa}$, B^λ is a covariant vector, etc. Conversely, if $A_\kappa B^\kappa$ is a scalar for *any* covariant vector A_κ, B^κ is a contravariant vector. Similarly, if $A_{\iota\kappa}B^{\iota\kappa}$ is a scalar for any covariant $A_{\iota\kappa}$, $B^{\iota\kappa}$ is contravariant; if $A^{\iota\kappa}B_{\iota\kappa\lambda}=C_\lambda$ is covariant for any contravariant $A^{\iota\kappa}$, then $B_{\iota\kappa\lambda}$

is covariant. This is an efficient method of establishing the tensor character of a set of n, n^2, n^3, etc. magnitudes.

Differentiation.—The differentiation of tensors with respect to the co-ordinates yields, in certain circumstances, further tensors. If f is a scalar function of the x, or scalar field, $\partial f/\partial x_\iota = f_\iota$ is a covariant vector, the ***gradient*** of f (but $\partial^2 f/\partial x_\iota \partial x_\kappa$ is not a tensor; again, if du be an invariant, dx_ι/du is, but d^2x_ι/du^2 is not a vector). Further, if A_ι be a vector, $B_{\iota\kappa} = \partial A_\iota/\partial x_\kappa - \partial A_\kappa/\partial x_\iota$ is a skew tensor, *the rotation* of A_ι. Finally, if $A_{\iota\kappa}$ be antisymmetric, $B_{\iota\kappa\lambda} = \partial A_{\iota\kappa}/\partial x_\lambda + \partial A_{\kappa\lambda}/\partial x_\iota + \partial A_{\lambda\iota}/\partial x_\kappa$ is again such a tensor, *the expansion* of $A_{\iota\kappa}$. Differentiation, unaided by metrics, does not seem to yield any other noteworthy tensors.

In what precedes only such properties of tensors were treated as are independent of any metrical considerations, the space S_n being thus far a non-metrical, amorphous manifold. Let now its metrics be fixed by laying down the ***line-element***, a quadratic differential form with coefficients $g_{\iota\kappa} = g_{\kappa\iota}$, prescribed functions of the x,

$$ds^2 = g_{\iota\kappa} dx_\iota dx_\kappa, \tag{2}$$

to be considered as ***invariant*** and to serve as the measure of the (squared) size or length of the vector dx_ι. Then, dx_ι being contravariant, $g_{\iota\kappa}$ will be covariant. Equivalently we may say that a certain symmetrical tensor $g_{\iota\kappa}$ is being impressed upon S_n as the *fundamental* or *metrical tensor*, converting it into a metrical manifold, a *Riemannian space*. Then $g_{\iota\kappa}dx_\iota dx_\kappa$ will be an invariant, the squared size, of the vector dx_ι which had no invariant of its own. In relation to or with the aid of $g_{\iota\kappa}$, all other vectors and higher tensors will now acquire some new properties. These, and these only, will be their metrical properties. Thus, $g_{\iota\kappa}A^\iota A^\kappa$ is the invariant squared size (A^2) or ***norm*** of a vector A^ι, $g_{\iota\kappa}\, B^{\iota\kappa} = B$ the scalar of $B^{\iota\kappa}$, and $g_{\iota\kappa}g_{\lambda\mu}C^{\iota\kappa\lambda\mu}$ that of $C^{\iota\kappa\lambda\mu}$.

The minors $g^{\iota\kappa}$ of $g = |g_{\iota\kappa}|$, divided by g, form again a symmetrical tensor, the contravariant metrical tensor, to be used along with $g_{\iota\kappa}$. Thus $g^{\iota\kappa}X_\iota X_\kappa$ is the norm of X_ι. With every vector A_ι there is metrically associated a contravariant vector $g^{\iota\kappa}A_\kappa = A^\iota$, the *conjugate* of A_ι; similarly, $g_{\iota\kappa}B^\kappa = B_\iota$, the conjugate of B^ι. The conjugate of the conjugate is the original vector. Conjugate vectors, B_ι and B^ι, have the same size, the norm of either being expressible by $B_\iota B^\iota$. These properties follow from the important formula $g_{\kappa\alpha}g^{\kappa\beta} \equiv g^\beta_\alpha = \delta_{\alpha\beta}$, where $\delta_{\alpha\beta}$ is Kronecker's symbol, 0 or 1, according as $\alpha \neq \beta$ or $\alpha = \beta$. This symbol, more appropriately δ^β_α is itself a mixed tensor. Similarly, metrical associates are constructed from higher tensors. Thus, to $A_{\iota\kappa}$ belongs $A^{\iota\kappa} = g^{\alpha\iota}g^{\beta\kappa}A_{\alpha\beta}$, its ***supplement***. The supplement of the supplement is the original tensor. With the covariant $A_{\iota\kappa}$ is metrically associated the mixed tensor $A^\iota_\kappa = g^{\iota\alpha}A_{\kappa\alpha}$ and the covariant tensor $a_{\iota\kappa} = g_{\iota\kappa}g^{\alpha\beta}A_{\alpha\beta} = A g_{\iota\kappa}$, *the reduced* of $A_{\iota\kappa}$.

The angle θ between two (copunctal) vectors is defined by the invariant $\cos\theta = g^{\iota\kappa}A_\iota B_\kappa/AB = A^\kappa B_\kappa/AB$; A, B being their sizes. For contravariant vectors, $\cos\theta = g_{\iota\kappa}A^\iota B^\kappa/AB$. The unit vector $\dot{x}_\iota = dx_\iota/ds$ determines, locally, a ***direction*** in S_n. The angle between two directions $\dot{x}_\iota$, $\dot{y}_\iota$ is given by $\cos\theta = g_{\iota\kappa}\dot{x}_\iota\dot{y}_\kappa$.

Integrals.—The integral $\int dx_1 \ldots dx_n$, briefly $\int dx$, extended over a region of S_n, is transformed into $\int J dx'$, and the determinant g into $g' = J^2 g$. Consequently, $\int \sqrt{g}dx$ is an invariant metrically impressed upon that region, its size or ***volume*** (area, if $n = 2$). This concept is readily extended to any sub-manifold of S_n characterized by x_ι as functions of $m < n$ parameters p_a, the rôle of metrical tensor being taken over by

$$h_{ab} = g_{\iota\kappa}(\partial x_\iota/\partial p_a)(\partial x_\kappa/\partial p_b).$$

If, by a proper choice of the co-ordinate system, all components $g_{\iota\kappa}$ are reducible to constants, the metrical space S_n is Euclidean or homoloidal (flat). This is but a very special case of a Riemannian space. In general such a reduction is not possible, and S_n is non-Euclidean (*v. infra*).

Differentiation of tensors, aided by metrics, yields an unlimited number of new tensors. The oldest of such is Riemann's set of four-index symbols, of 1861. The simplest metrically differential tensor, however, was discovered in 1869 by Christoffel. This is ***the covariant derivative*** of a vector A_ι,

$$A_{\iota\kappa} = \frac{\partial A_\iota}{\partial x_\kappa} - \{\iota\kappa, \lambda\} A_\lambda, \tag{3}$$

where $\{\iota\kappa, \lambda\} = g^{\lambda\mu}[\iota\kappa, \mu] = \{\kappa\iota, \lambda\}$ and

$$[\iota\kappa, \mu] = \tfrac{1}{2}(\partial g_{\iota\mu}/\partial x_\kappa + \partial g_{\kappa\mu}/\partial x_\iota - \partial g_{\iota\kappa}/\partial x_\mu)$$

are Christoffel's symbols (***not*** forming a tensor). Again,

$$B^\iota_\kappa = \partial B^\iota/\partial x_\kappa + \{\alpha\kappa, \iota\} B^\alpha$$

is a mixed tensor, and $g^{\kappa\lambda}B^\iota_\kappa = B^{\iota\lambda}$ is *the contravariant derivative* of B^ι. Likewise,

$$C^{\iota\kappa}_\lambda = \partial C^{\iota\kappa}/\partial x_\lambda + \{\lambda\alpha, \iota\} C^{\alpha\kappa} + \{\lambda\alpha, \kappa\} C^{\iota\alpha}, \tag{4}$$

$$C_{\iota\kappa\lambda} = \partial C_{\iota\kappa}/\partial x_\lambda - \{\iota\lambda, \alpha\} C_{\alpha\kappa} - \{\kappa\lambda, \alpha\} C_{\iota\alpha} \tag{5}$$

are the covariant derivatives of $C^{\iota\kappa}$ and $C_{\iota\kappa}$. The covariant derivative of $g_{\iota\kappa}$ itself vanishes identically. Noteworthy for their applications are

$$A^\iota = \mathrm{Div}(A^{\iota\kappa}) \equiv \frac{1}{\sqrt{g}} \frac{\partial}{\partial x_\kappa} (\sqrt{g}A^{\iota\kappa}) \text{ and } \mathrm{div}(A^\kappa) \equiv \frac{1}{\sqrt{g}} \frac{\partial}{\partial x_\kappa} (\sqrt{g}A^\kappa),$$

the vector divergence of a skew $A^{\iota\kappa}$ and *the scalar divergence* of A^κ; *e.g.*, one group of Maxwell's equations is represented by $\mathrm{Div}(F^{\iota\kappa}) = C^\iota$, where C^ι is the four-current and $F^{\iota\kappa}$ the electromagnetic skew tensor (six vector); the second group being expressed by equating to zero the "expansion" (*v. supra*) of $F_{\iota\kappa} = g_{\iota\alpha}g_{\kappa\beta}F^{\alpha\beta}$.

Geodesics, Null-lines.—The most characteristic lines of the metrical S_n are its *null* or *minimal-lines*, $ds = 0$, and "shortest" lines or *geodesics* defined by $\delta\int ds = 0$, with fixed terminals. The equations of a geodesic are

$$\ddot{x}_\iota + \{\alpha\beta, \iota\}\dot{x}_\alpha\,\dot{x}_\beta = 0, \tag{6}$$

where $\dot{x} = dx/ds$. They determine, *e.g.*, in the case of space-time, the motion of a free particle in the metrical, and gravitational, field $g_{\iota\kappa}$. The null-lines are imaginary or real according as (2) is a definite or non-definite form. The former is the case of spaces proper as contemplated by the pure geometer, and the latter that of space-time with one positive and three negative $g_{\kappa\kappa}$. The null-lines of space-time represent light propagation. The definiteness or non-definiteness of the quadratic form and its *index of inertia* (number of negative $g_{\kappa\kappa}$'s) are invariant properties.

Differential Parallelism.—A fruitful contribution to tensor analysis, due to Levi-Civita (1917), is the concept of differential *parallelism*. The metrical S_n can always be imagined as hypersurface embedded in a Euclidean space E, of $\frac{1}{2}n(n+1)$ dimensions. $O(x_\iota)$ and $O'(x_\iota + dx_\iota)$ being points of S_n, and OP a vector, Levi-Civita transfers OP by a Euclidean parallel shift to $O'P_e$ and defines $O'P'$, the orthogonal projection of $O'P_e$ upon the E-plane tangential to S_n at O, as *parallel* to OP. In spite of the ultra-spacial construction, parallelism is intrinsic, expressible by the S_n-metrics alone. If A^ι be the components of OP, and $A^\iota + \delta A^\iota$ those of $O'P'$,

$$\delta A^\iota = -\{\kappa\lambda, \iota\} A^\kappa dx_\lambda. \tag{7}$$

For covariant components, $\delta A_\kappa = \{\kappa\lambda, \iota\} A_\iota dx_\lambda$. These formulae give, in any co-ordinates, the changes of the components of a vector produced by its translation or parallel shift through dx_λ. In local geodesic co-ordinates ($g_{\iota\kappa}$ stationary at O), $\delta A_\kappa = 0$. Alternatively, after Weyl, parallelism may be defined in the non-metrical S_n by putting $\delta A^\iota = -\Gamma^\iota_{\lambda\kappa}A^\kappa dx_\lambda$, where $\Gamma^\iota_{\lambda\kappa} = \Gamma^\iota_{\kappa\lambda}$ are freely prescribable functions of position, fixing *the affine connection* of the otherwise amorphous manifold. One can continue to hold this more general, affine view in developing further consequences, as of late was done by many writers; but this subject cannot here be dwelled upon. If metrics are impressed upon the affine manifold, the requirement that the size of a vector shall remain unaltered by a translation, $\delta(g_{\iota\kappa}A^\iota A^\kappa) = 0$, gives $\Gamma^\iota_{\lambda\kappa} = \{\kappa\lambda, \iota\}$, leading again to (7).

The parallel shift is a powerful means of obtaining differential tensors. Being the difference of not copunctal vectors, δA_κ is not a vector; but, if A_κ be considered as a field, its value at O' is $A_\kappa + \dfrac{\partial A_\kappa}{\partial x_\lambda}\, dx_\lambda$, while the vector transferred from O to O' is

$A_\kappa+\delta A_\kappa$. These two being copunctal, their difference

$$[\partial A_\kappa/\partial x_\lambda-\{\kappa\lambda,\iota\}A_\iota]dx_\lambda$$

is a covariant vector; and dx_λ being arbitrary, the bracket is a tensor $A_{\kappa\lambda}$. This establishes the covariance of Christoffel's derivative (3), which now appears as the point-to-point change of the field A_κ *less* that due to translation. The same process can be applied to a $C_{\iota\kappa}$, defining its translation by the requirement $\delta(C_{\iota\kappa}A^\iota B^\kappa)=0$, for any vectors A^ι, B^κ. This leads to the covariant derivative $C_{\iota\kappa\lambda}$ (5) Similarly for higher-rank tensors. Any of these covariant differentiations can be written

$$\mathfrak{D}_\lambda=\frac{\partial}{\partial x_\lambda}-\frac{\delta}{dx_\lambda},$$

where δ/dx_λ stands for the factor of dx_λ in the expression of δ.

Let it be required to construct a line whose elements follow from each other by parallel shifts along the line itself. This gives $\delta\dot{x}_\iota=-\{\alpha\beta,\iota\}\dot{x}_\alpha dx_\beta$ and $\delta x_\iota=\dot{x}_\iota ds$, so that the line is a geodesic The latter is thus throughout "parallel to itself"—an interesting generalization of the property of Euclidean straights. Accordingly, a vector transferred along a geodesic remains equally inclined to it.

The concept of parallelism opens also an easy road to the very important Riemann-Christoffel tensor. This is formed of the $g_{\iota\kappa}$ and their first and second derivatives, and represents thus a differential, second-order property of the metrical field itself. Significantly enough, there is no such property of the first order; in fact, the tensor $\mathfrak{D}_\lambda g_{\iota\kappa}$ vanishes, and there is no other. This lends additional interest to the second-order tensor

If a vector X^ι be carried by successive parallel shifts along two different paths a, b from O to a distant point O', the two vectors at O', equal in size, generally differ in direction One is parallel to X^ι "*via a*," the other "*via b*" In fine, parallelism depends on the route of transfer or is non-integrable (unless S_n is Euclidean). Thus also, if the vector be carried around a *circuit*, it returns at O with its direction changed. The total change of X^κ,

$$\Delta X^\kappa=\int\delta X^\kappa=-\int\{\kappa\lambda,\iota\}X^\kappa dx_\lambda,$$

being the difference of copunctal vectors, is itself a vector. Evaluate the integral for a quadrilateral x, $x+dx$, $x+dx+dy$, $x+dy$. Then

$$\Delta X^\kappa=\left[\frac{\partial}{\partial x_\beta}\{\iota\alpha,\kappa\}-\{\alpha\gamma,\kappa\}\{\iota\gamma,\beta\}\right]X^\iota\sigma^{\alpha\beta},$$

where $\sigma^{\alpha\beta}=dx_\alpha dy_\beta-dx_\beta dy_\alpha$ This, the oriented surface-element, being antisymmetric, the equation holds also when α,β are interchanged Thus,

$$\Delta X^\kappa=-\tfrac{1}{2}R^\kappa_{\iota\alpha\beta}X^\iota\sigma^{\alpha\beta}, \tag{8}$$

where

$$R^\kappa_{\iota\alpha\beta}=\frac{\partial}{\partial x_\alpha}\{\iota\beta,\kappa\}-\frac{\partial}{\partial x_\beta}\{\iota\alpha,\kappa\}+\{\alpha\gamma,\kappa\}\{\iota\beta,\gamma\}-\{\beta\gamma,\kappa\}\{\iota\alpha,\gamma\} \tag{9}$$

is again antisymmetric in α,β Therefore, and since ΔX^κ is a vector, $R^\kappa_{\iota\alpha\beta}$ is a mixed tensor This is *the Riemann-Christoffel* or *curvature tensor*. Its meaning is best expressed by (8) itself, which reads: the change of a vector carried around an oriented surface-element is half the inner product of the curvature tensor into that element and the vector. An alternative deduction of $R^\alpha_{\iota\kappa\lambda}$ can be briefly expressed by

$$(\mathfrak{D}_\lambda\mathfrak{D}_\kappa-\mathfrak{D}_\kappa\mathfrak{D}_\lambda)X_\iota=R^\alpha_{\iota\kappa\lambda}X_\alpha.$$

The vanishing of the curvature tensor is the necessary and sufficient condition for the reducibility of $g_{\iota\kappa}$ to a constant tensor, or the criterion of a homaloidal (Euclidean) space. In fact, if $g_{\iota\kappa}(x)$ is constant throughout S_n, all Christoffel symbols and $R^\kappa_{\iota\alpha\beta}$ vanish in x and therefore also in any co-ordinate-system. Conversely, if $R^\kappa_{\iota\alpha\beta}$ vanishes, $\Delta X^\kappa=0$ for every circuit, parallelism becomes independent of the route of transfer and applicable to any pair of distant places. This however can be shown to be sufficient for constructing the Euclidean geometry. Analytically, the sufficiency of this condition for the reducibility of $g_{\iota\kappa}dx_\iota dx_\kappa$ to a form with constant coefficients was proved by Lipschitz as early as 1869.

Riemann's Four-index Symbols and Curvature.—Riemann's own set of *four-index symbols* is the covariant tensor $(\iota\mu,\lambda\kappa)\equiv R_{\iota\mu\lambda\kappa}=g_{\mu\alpha}R^\alpha_{\iota\kappa\lambda}$. Conversely, $R^\alpha_{\iota\kappa\lambda}=g^{\mu\alpha}(\iota\mu,\lambda\kappa)$. Like (9), the symbols are antisymmetric in κ,λ. Three more linear relations hold between them. This reduces the number of independent symbols to $\frac{1}{12}n^2(n^2-1)$; *e.g.*, six for a three-space, twenty for an S_4, and but *one* for a surface, say (12, 12). This symbol divided by g is an invariant of the surface, its *Gaussian curvature* (K.) (*See* DIFFERENTIAL GEOMETRY.) Formula (8) gives for the rotation of a two-vector carried around a surface-element (of area $d\sigma=\sqrt{g}\sigma^{12}$), $\Delta\theta=Kd\sigma$; the vector on its return overshoots its original direction or falls short of it by $|K|d\sigma$ according as $K\gtrless 0$. The Gaussian curvature thus appears as the rotation per unit area. As a consequence, *the excess* (over π) of the angle sum in any geodesic triangle is $\int Kd\sigma$, the "total curvature" of the triangle, a famous theorem due to Gauss.

In the case of three or more dimensions the curvature properties can no longer be expressed by a single magnitude, but require for their description the knowledge of the whole curvature tensor or the associated Riemann symbols. The concept of Gaussian curvature is now replaced by that of *Riemannian curvature*. This is, at any point $O(x)$ of S_n, the set of Gaussian curvatures K_ν of geodesic surfaces of all possible orientations laid through O. If $h_{\alpha\beta}$ be the metrical tensor of such a surface as sub-manifold, then $K_\nu=\frac{1}{h}(12,12)_h$, the symbol to be calculated with $h_{\alpha\beta}$. This and the determinant h can be expressed in terms of the tensor $g_{\iota\kappa}$ of the manifold and the vector pair, $d\xi_\iota$, $d\eta_\iota$, fixing the orientation. The result is

$$K_\nu=\frac{(\iota\lambda,\kappa\mu)\sigma^{\iota\lambda}\sigma^{\kappa\mu}}{(g_{\iota\kappa}g_{\lambda\mu}-g_{\iota\mu}g_{\lambda\kappa})\sigma^{\iota\lambda}\sigma^{\kappa\mu}},\qquad(\iota<\lambda,\ \kappa<\mu), \tag{10}$$

where $\sigma^{\iota\lambda}=d\xi_\iota d\eta_\lambda-d\xi_\lambda d\eta_\iota$ is the oriented surface-element (the suffix ν indicating its normal). In general, K_ν will depend on position and on orientation In other words, with regard to curvature, S_n may be non-homogeneous as well as anisotropic (*e g*, space-time within or around matter), but if K_ν is everywhere isotropic, it is also constant throughout S_n. This is Schur's theorem. By (10) the necessary and sufficient condition for isotropy of Riemannian curvature becomes $(\iota\lambda,\kappa\mu)=K(g_{\iota\kappa}g_{\lambda\mu}-g_{\iota\mu}g_{\lambda\kappa})$ or $R^\alpha_{\iota\kappa\lambda}=K(\delta^\alpha_\kappa g_{\iota\lambda}-\delta^\alpha_\lambda g_{\iota\kappa})$ with constant K.

The tensor (9), being mixed, yields the contracted curvature tensor $R^\alpha_{\iota\kappa\alpha}=R_{\iota\kappa}$ which turns out to be symmetrical. Its scalar, $R=g^{\iota\kappa}R_{\iota\kappa}$, is the *curvature invariant* of the manifold. For an isotropic n-fold, $R=-(n-1)nK$ and $R_{\iota\kappa}=g_{\iota\kappa}R/n$. A capital use of $R_{\iota\kappa}$ was made by Einstein for constructing the gravitational field-equations, $R_{\iota\alpha}-\frac{1}{2}Rg_{\iota\alpha}=-\kappa T_{\iota\alpha}$, where $\kappa\propto$ gravitation constant, and $T_{\iota\alpha}$ is the tensor of matter, embodying energy, momentum, and stress. The covariant derivative of $R_{\iota\kappa}$ is connected with grad R by the n relations $g^{\kappa\lambda}R_{\iota\kappa\lambda}=\frac{1}{2}\partial R/\partial x_\iota$, which were again utilized by Einstein and which follow from the identical relations $\mathfrak{D}_\nu(\iota\kappa,\lambda\mu)+\mathfrak{D}_\lambda(\iota\kappa,\mu\nu)+\mathfrak{D}_\mu(\iota\kappa,\nu\lambda)=0$. These remarkable identities, discovered by Bianchi, give also a very simple proof of Schur's theorem.

TENTERDEN, CHARLES ABBOTT, 1ST BARON (1762–1832), lord chief justice of England, was born at Canterbury on

Oct. 7, 1762, the son of a hairdresser. He was educated at Canterbury King's school and Corpus Christi college, Oxford, and entered at the Middle Temple in 1787. For several years he practised as a special pleader under the bar, and was finally called at the Inner Temple in 1796. He joined the Oxford circuit and made rapid headway. In 1801 he was appointed recorder of Oxford. In 1802 appeared his *Law relative to Merchant Ships and Seamen*, which is still an authoritative work. Its publication brought to him so much commercial and other work that in 1808 he was in a position to refuse a seat on the bench; this, however, he accepted in 1816, being made a judge of the court of common pleas. On the resignation of Lord Ellenborough in 1818 he was promoted to the chief justiceship of the king's bench, and presided over several important state trials, notably that of Arthur Thistlewood and the Cato Street conspirators (1820). He was raised to the peerage in 1827 as Baron Tenterden of Hendon. Never a great lawyer and with no pretence to eloquence, Tenterden made his way by sound common sense and steady hard work. He was an uncompromising Tory, and had no sympathy with the reform of the criminal law carried out by Romilly; while he strongly opposed the Catholic Relief bill and the Reform bill. He died on Nov. 4, 1832.

See Foss, *Lives of the Judges* (1870).

TENTERDEN, a market town and municipal borough in the Ashford parliamentary division of Kent, England, 53 m. S.E. by E. of London by the S. railway. Pop. (1921) 3,438. It lies on an elevation above the Newnill channel, a tributary of the Rother, whose flat valley, called the Rother Levels, was an estuary within historic times; and even as late as the 18th century the sea was within 2 m. of Tenterden, which is a member of the affiliated Cinque Port of Rye. The church of St. Mildred is Early English and later, and its tall, massive Perpendicular tower is well known for the legend connecting it with Goodwin Sands. The story is that the abbot of St. Augustine, Canterbury, diverted the funds by which the sea-wall protecting Earl Godwin's island was kept up, for the purpose of building Tenterden steeple, the consequence being that in 1099 an inundation took place and "Tenterden steeple was the cause of the Goodwin Sands." The church of High Halden, in the neighbourhood, is remarkable for its octagonal wooden tower constructed of huge timbers, with a belfry of wooden tiles (shingles), of the time of Henry VI.

Tenterden (*Tenterdenne, Tentyrden*) figures frequently in contemporary records from 1300 onwards. In 1449 it was united to Rye, and granted a charter which, however, did not come into operation till 1463 under Edward IV. In return for these and other privileges it was to contribute towards the services due from Rye as one of the Cinque Ports. In 1600 it was incorporated under the title of the "Mayor, Jurats and Commons" of the town and hundred of Tenterden, in the county of Kent, the members of the corporation ranking henceforward as barons of the Cinque Ports. A weekly corn market on Friday and a yearly cattle and wool fair on the first Monday in May were granted, both of which are held at the present day. In 1790 a contemporary writer mentions the market as being little frequented, whilst the fair was large and resorted to by all the neighbourhood. The size and importance of Tenterden can be estimated from a receipt of 1635 for £90 ship-money, as compared with £70 contributed by Faversham, and £60 by Hythe. Under Edward III. several refugee Flemings settled in the town and established the woollen manufacture. By 1835 this trade died out.

TENURE, in law, the holding or possession of land. The holding of land in England was originally either *allodial* or *feudal*. Allodial land was land held not of a superior lord, but of the king and people. Such ownership was absolute (*see* ALLODIUM). The Saxon invasion tended, without doubt, to re-establish the principle of common village ownership which formed the basis of both Celtic and German tenure. In the later Saxon period, however, private ownership became gradually more extended. Then the feudal idea began to make progress in England, much as it did about the same time on the Continent of Europe, and it received a great impetus from the Norman conquest. When English law began to settle down into a system the principle of feudalism was taken as the basis, and it gradually became the undisputed maxim of English law that the Sovereign was the supreme lord of all the land and that every one held under him as tenant (*see* FEUDALISM). All tenures, except free and common socage tenures, were abolished by the Law of Property Act, 1925 (s. 56), and provision has been made for the abolition of copyhold and customary tenure and the extinction of manorial incidents, with a saving for grand and petty serjeanty services (*ibid.* ss. 128, 136, 139–143). The following modern cases may be consulted with regard to native tenures of land: *In re Southern Rhodesia* (1919) A.C. 211, 233 (aboriginal rights generally); *Sobhn Za II.* v. *Miller* (1926) A.C. 518 (West African); *Amadu Tijani* v. *Secretary for Southern Nigeria* (1921) 2 A.C. 399 (West African); *A.G. for Quebec* v. *A.G. for Canada* (1921) 1 A.C. 401 (Indian Reserves): but it should be noted that in several colonies the matter has been the subject of legislation. In the United States the term tenure ordinarily is used to denote the manner whereby lands or tenements are held, excluding lands held in fee simple. As an example, a person may have a life estate or tenure in land, or a tenure for a term of years. (*See* also ESTATES; LAND; MANOR.)

TEOSINTE (*Euchlaena mexicana*), a tall, stout, annual grass, native to Mexico, very closely allied botanically to maize (*q.v.*). Usually branching at the base, it grows in large clumps, with tassels (staminate flowers) like those of maize. The bundles of fruiting spikes, enclosed in husks, with the silk (long styles) hanging from the upper ends, are somewhat similar to the ears of maize. Teosinte is grown in Mexico as a fodder plant and sparingly in the southern parts of the United States as a soiling crop. In Mexico hybrids of teosinte and maize are found, giving rise to the view that the two plants have developed from a common ancestral form.

TEPIDARIUM, the warm room of a Roman bath (*see* BATHS), or a similar chamber in a modern bath establishment. In the great imperial thermae at Rome the tepidarium constituted the large central hall and served, apparently, as a general lounge and meeting room as well as for bathing.

TEPLICE-ŠANOV, a spa in Bohemia, Czechoslovakia, in the valley of the Bilina. It owes its popularity as a watering-place to its mild climate and to the thermal mineral springs of the locality. The saline-alkaline waters, 79° to 122° F, are used almost exclusively for bathing in the treatment of gout, rheumatism and some skin complaints and are prescribed as an "after-cure" to Carlsbad, etc. Although traditionally believed to have been known and used since the 8th century, the springs are not historically mentioned until the 16th century, and to-day the function of the town as a watering-place is disappearing in face of the advance of industry, for the rich lignite field of Most-Chomůtov-Teplice has led to the establishment of numerous manufactures. Hardware, machinery, glass, pottery, chemicals, cotton and woollen goods are the principal products and in all of these Teplice has a brisk trade that increases yearly. Industrial life grows mainly in the suburbs. Pop. (1923) 28,892, of whom 22,489 were Germans.

TEPLITZ: *see* TEPLICE-ŠANOV.

TERAMO, an episcopal see of the Abruzzi, Italy, the capital of the province of Teramo, 16 m. by rail W.S.W. of Giulianova, a junction on the Ancona-Brindisi railway. Pop. (1921) 15,284 (town); 25,834 (commune). The town stands on the left bank of the Tordino, where it is joined by the Vezzola, at an altitude of 876 ft. above sea-level. The cathedral has a Romanesque Gothic portal of 1332 by a Roman marble worker named Deodatus; it contains a splendid silver antependium by Nicolo da Guardiagrele (1433–48). The tower is fine. The church of S. Antonio is also in the Romanesque Gothic style. Under the church of S. Anna dei Pompetti remains of Roman houses and of the original cathedral have been discovered. Two m. away is an important astronomical observatory, presented to the State by Vincenzo Cerulli in 1917. The ancient Interamna Praetuttiorum was the chief town of the tribe of the Praetuttii.

TERAPHIM, a Hebrew word, found only in the plural, of uncertain etymology. The name appears to be applied to some form of idol (*cf.* Gen. xxxi. 19 and 30), but details as to its pre-

cise configuration, etc., are lacking. From I. Sam. xix. 13, 16 it would seem that in the early monarchical period a regular place in every household was still reserved for the teraphim; while in the 8th century, Hosea (iii. 4) speaks of "ephod and teraphim" as essential elements in the national worship. Later the teraphim were banned by the prophets. The meaning of the story in Gen. xxxv. 2–4 clearly is that the employment of teraphim was given up by Israel in order that they might serve Jehovah alone at Bethel. In Judges and Hosea the teraphim are closely associated with the ephod; both are mentioned in connection with divination (*cf.* 2 Kings xxiii. 24; Ezek. xxi. 21 & 26; Zech. x 2). In view of Ezek. xxi. 21 and Hosea iii. 4, it is difficult to suppose that the teraphim were purely household idols. *See* also EPHOD.

TERBIUM, a very rare metallic element (symbol Tb, atomic number 65, atomic weight 159·2) of the rare-earth group, was discovered by Mosander, who originally named the oxide erbia. The first pure compounds were obtained by G. Urbain in 1905. It is best separated from the other members of the group by the fractional crystallization of the bromates. The ignition of terbium oxalate or sulphate gives a black peroxide which slowly dissolves on heating with mineral acids, giving almost colourless solutions characterized by a rather faint absorption band in the blue region of the spectrum. *See* RARE EARTHS. (C. J.)

TER BORCH (or TERBURG), **GERARD** (1617–1681), Dutch subject painter, was born in 1617 at Zwolle, Holland He received an excellent education from his father, also an artist, and developed his talent very early The inscription on a study of a head proves that Ter Borch was at Amsterdam in 1632 In 1634 he studied under Pieter Molyn in Haarlem. A record of this Haarlem period is the "Consultation" (1635) at the Berlin gallery. In 1635 he was in London; in 1640 in Rome, when he painted the small portraits on copper of "Jan Six" and "A Young Lady" (the late Six collection, Amsterdam). In 1648 he was at Münster during the peace congress and executed his celebrated little picture, painted upon copper, of the assembled plenipotentiaries—a work which, along with the "Guitar Lesson" and a portrait of a "Man Standing," now represents the master in the National Gallery in London The picture was presented to the nation by Sir Richard Wallace. At this time Ter Borch was invited to visit Madrid, where he received employment and the honour of knighthood from Philip IV , but, in consequence of an intrigue, it is said, he was obliged to return to Holland. He seems to have resided for a time in Haarlem; but he finally settled in Deventer, where he became a member of the town council He died at Deventer on Dec. 8, 1681

Ter Borch is excellent as a portrait painter, but still greater as a painter of *genre* subjects. He depicts with admirable truth the life of the wealthy and cultured classes of his time. His colouring is clear and rich, but his best skill lies in his unequalled rendering of texture in draperies, which is seen to advantage in such pictures as the "Letter" in the Dutch royal collection, and in the "Paternal Advice" (known as the "Satin Gown")—engraved by Wille—which exists in various repetitions at Berlin and Amsterdam, and in the Bridgewater gallery. Hofstede de Groot enumerates 464 works by Ter Borch. Seven of these are at the Hermitage, 12 at the Berlin museum, seven at the Louvre; six at the Dresden museum, two at the Wallace collection and 15 at the Amsterdam museum.

See Hofstede de Groot, *Catalogue of Dutch Painters* (1913).

TERCEIRA, an island in the Atlantic ocean, belonging to Portugal, and forming part of the Azores archipelago Pop. (1911) 47,953; area, 224 sq.m. Terceira, *i.e.,* "the third," was so called as being the third island of the archipelago to be discovered by the Portuguese. From its central position it was long the seat of administration, but its capital, Angra (*q.v.*), has lost much of its commercial importance. The other chief towns are Ribeirinha (2,739), and Praia da Vitoria (3,195). (*See* AZORES)

TEREBINTH, botanical name *Pistacia terebinthus,* a member of the family Anacardiaceae, usually a small tree, common in the south of Europe and the whole Mediterranean area. It has a purplish grey bark and compound leaves with two to four pairs, and an odd terminal one The very small numerous unisexual flowers are borne on panicles. The fruit is a small roundish bright red drupe with a scanty pulp. The plant has been long known in English gardens. A liquid resinous exudation, known as Chian, Scio or Cyprus turpentine, is obtained by cutting the stem. An allied species, *P. lentiscus,* is the mastic tree.

TEREDO. From time immemorial seafaring men have known and dreaded the shipworm, which bores into and destroys the stoutest timbers in the sea. Nowadays, although the danger to ships is no longer to be feared, the timber of harbour works is still exposed to damage by the same pest. How serious the danger may become is shown, for example, by the outbreak of shipworm in San Francisco bay during the four years 1917–21 when the destruction of wharves and jetties was estimated to have cost the enormous sum of 25 million dollars

The writers of antiquity did not distinguish clearly between the marine timber-worm and the wood-boring insect larvae of the land and they sometimes applied the name Teredo to both, but it was later restricted to the marine borer and is still in use as a general term for the shipworms, although in the nomenclature of zoological taxonomy it is the name of only one of the genera forming the family Teredinidae.

It was Godfrey Sellius who, in 1733, first showed that *Teredo* is a bivalve mollusc, although it differs widely in structure from the more familiar members of that group. When its burrow in the wood is laid open it is seen to have a long worm-like body bearing at its inner end a pair of small shelly plates which represent the valves of the shell. At the outer end, where the burrow narrows to a small opening, the body ends in a pair of siphons which can be extended from the surface of the wood and serve for the entrance and exit of the respiratory current of water When the siphons are withdrawn the opening of the burrow is blocked by a pair of paddle-shaped plates of shell known as the pallets. The interior of the burrow is lined with shelly material which is usually merely a thin film but when exposed by the decay of the wood may be considerably thickened. The valves of the shell are nearly hemispherical, with a deep right-angled notch occupying the ventral half of the anterior margin. In the gap left by these notches is the round sucker-like foot with which the animal adheres now to one part and now to another of the interior of its burrow Parallel with the edges of the notch, the surface of each valve is marked with two sets of fine ridges which are seen under the microscope to be rows of minute teeth like those of a file. It is by means of these teeth that the excavation of the wood is effected. While the foot is adhering to the wood a rocking movement is imparted to the valves by alternate contractions of the anterior and posterior adductor muscles and the wood is rasped away as a fine dust This is swept into the mouth and passes into the stomach. It has been shown beyond doubt that the wood is acted on by the digestive ferments and utilized as food, but in addition the stomach is usually found to contain minute floating organisms drawn in with the respiratory current

In some species of *Teredo* the eggs are discharged and float freely in the sea, in others they are retained in the gill-cavity and pass through the early stages of their development before they are set free. In either case, the earliest stage is a free-swimming ciliated larva which soon develops a bivalve shell After a time the larva settles on the surface of the wood, creeping about by means of a large tongue-shaped muscular foot. Settling on a suitable spot it begins to scrape away the wood with the edges of the valves and soon disappears below the surface. As the burrow deepens the body lengthens so that the siphons can protrude from the surface while the valves are working at the inner end. In temperate seas shipworms rarely exceed a foot in length but some tropical species may reach six feet.

Many species of shipworms have been described and grouped in a number of genera forming the family Teredinidae, but the taxonomy is not in a satisfactory condition and much more work is required before the limits of species or genera can be properly defined. What is of importance to the engineer is that the different species differ considerably in their physiological requirements. Thus while many species are only able to flourish in places where the salinity of the water is nearly the same as that of the open

sea, the typical species *Teredo navalis* can survive a considerable reduction in the salinity and is enabled to invade estuaries and harbours where the influx of fresh water excludes other species. It happens from time to time, as in the case of the San Francisco outbreak alluded to above, that a temporary increase of salinity resulting from reduced rainfall allows *T. navalis* to gain a footing in places where it had not previously existed.

Numerous methods have been tried for protecting timber against the attacks of shipworms. Metal sheathing for the hulls of wooden ships was employed in Greek and Roman times and copper sheathing came into extensive use in the 18th century. At the present day the piles of harbour works are sometimes sheathed with metal or enclosed in concrete "jackets." These methods, however, are only effective when the surface is completely covered. A small space left unprotected may admit enough shipworm larvae to destroy completely the interior of the timber. Certain kinds of timber, such as the South American greenheart, are comparatively resistant to shipworm attacks but it appears that this resistance is only temporary and that no kind of wood is permanently immune. Many methods for impregnating the wood with poisonous substances have been tried, but the only agent that has come into general use for this purpose is creosote. Heavy impregnation with creosote greatly lengthens the "life" of timbers exposed to attack, but lasting immunity is not attained owing to the gradual washing out of the creosote from the wood.

Besides the shipworms several species of Crustacea are the cause of serious damage to timber in the sea. The best known of these is the "gribble," a tiny isopod which burrows in the superficial layers of the wood, reducing them to a spongy mass which is easily washed away, exposing fresh layers to attack. It is common in European waters and has been found in many other parts of the world. The damage done by it is visible on the surface and is less likely to attain serious proportions without being noticed than is that caused by the shipworm. (W. T. C.)

TEREK, a river of Russia flowing from the Caucasus Range to the Caspian Sea, rising in glaciers on Mount Kasbek. It skirts the Kasbek group on the south and west, and flows through a series of gorges. The most famous is the Darial gorge by which the Terek escapes to the plains on the north, its furious torrent flowing between wild granitic bare rocks and forming a contrast to the wooded limestone mountains beyond. The Georgian military road, built 1811–64, passes through the gorge and enabled Russia to establish her rule among the wild Caucasian mountain tribes. Below Vladikavkaz at the foot of a vast declivity, it collects the waters of the Gusel-don, Fiag-don, Ar-don and later receives the Urukh, and the Malka, with its affluents the Cherek and Baksu. It then flows through the steppe country at the northern foot of the Caucasus to the Caspian, being joined before it reaches the delta by the Sunja, a tributary receiving the Chanti or Argun, and fed by numerous sulphur streams, one of them, the Melchihi, rising in five hot springs which affect the temperature of the Melchihi for some distance. In spite of losses by evaporation and irrigation, the Terek still has a sufficiently large volume to enable it to spread out in a great delta, with branches shifting in flood time and changing their relative importance. This delta stretches for 70 m. along the coast. The coast line, like that of the Volga delta, is encroaching on the Caspian, and old shore lines may be traced considerably west of the present coast. Fishing villages which in 1825 stood on the coast line were 10 m. inland in 1855. Among the more important irrigation canals are the Eristov and Kurskiy, fed from the Malka; plans are under consideration for irrigation of part of the Nogai steppe, recently included in the Dagestan A.S.S.R. In its lower course the Terek flows above the level of the surrounding country.

TEREK PROVINCE: *see* North Caucasian Area.

TERENCE (Publius Terentius Afer) (*c.* 190–*c.* 159 B.C.), Roman comic poet, was born in Carthage and came to Rome as a slave in the house of Terentius Lucanus, a senator, by whom he was educated and manumitted. The little that is known of his life is almost entirely derived from a fragment of Suetonius, *De viris illustribus.* At Rome he was on friendly terms with Scipio Africanus the younger, C. Laelius, and Furius Philus. His six plays were produced 166–160 B.C. After the production of the last he went to Greece, apparently to procure more of Menander's plays. From this voyage he did not return. The place and manner of his death are very variously given.

His first play, the *Andria,* was produced in 166 B.C. The plot, which may be taken as typical, tells of the adventures of an Athenian girl, Pasibula, who is left in the charge of an uncle while her father goes abroad; how she is shipwrecked off the coast of Andros, where she is brought up, under the name of Glycerium, as the daughter of an Andrian, and returns to Athens; of her love affair with Pamphilus and its threatened frustration; and of her rediscovery of her father and her eventual marriage with Pamphilus, whose crafty slave, Davus, is as usual the mainspring of the plot. The play is an adaptation from two plays—a procedure known as *contaminatio*—of Menander, as we learn from the prologue 9 *seq.* "Menander wrote the *Andria* and the *Perinthia;* he who knows either, knows both, for the plots are not very different, though they differ in language and style. The poet's enemies object to this and maintain that plays should not be contaminated (*contaminari non decere fabulas*). Their knowingness shows that they know nothing, for the same criticism applies to Naevius, Plautus and Ennius, whom the poet takes as his models, preferring their 'negligence' to the 'obscure diligence' of his detractors." The opening scene is twice referred to by Cicero, who in *De Inventione,* i. 23, cites lines 50–53, 157, 168, and in *De Oratore* 40, *hic parvae consuetudinis—faciet patri* (*Andr.* 110–112).

His second play, *Hecyra,* or the Mother-in-Law, adapted from a play by Apollodorus, was produced in 165. The third, *Heautontimorumenos,* or the Self-Avenger, appeared in 163; the fourth, the Eunuchus (Eunuch), a "contamination" (*cf.,* prol. 30 *seq.*) of two plays of Menander, the *Eunuchus* and the *Kolax* (flatterer), in 161; and in the same year also the *Phormio,* adapted from the *Epidicazomenos* of Apollodorus. His last play, the *Adelphoe,* or the *Brothers,* a "contamination" of the "*Adelphoi*" of Menander and the *Sunapothneskontes* of Diphilus, was produced in 160.

With regard to the economy of his plays, it is to be noted that Terence uses the prologue no longer to introduce a play by an exposition of the plot, but after the manner of the Aristophanic *parabasis,* chiefly to reply to his critics—*cf. Andria, prolog.* 5 "*Nam in prologis scribundis operam abutitur Non qui argumentum naeret sed qui malevoli Veteris poetae maledictis respondeat;*" *i.e.,* the poet wastes his labour in writing prologues, not to explain the plot, but to reply to abuse of a malevolent old poet (Lavinius Luscus, preferred by Vulcatius Sedigitus to Ennius as a comic poet. Aul. Gell. xv. 24).

The comedy of Terence, like that of his exemplars, is a comedy of manners. The reader is conscious of having travelled a long way from the Olympian humour of Aristophanes. His merit—purity of Latinity—and his demerit—lack of comic power (*vis comica*)—are summed up in the famous epigram of Julius Caesar (Sueton. *Vita Terentii*):

> Tu quoque, tu in summis, O dimidiate Menander,
> Poneris et merito puri sermonis amator:
> Lenibus atque utinam scriptis adiuncta foret vis
> Comica, ut aequato virtus polleret amore
> Cum Graecis neque in hac despectus parte iaceres.
> Unum hoc maceror et doleo tibi desse, Terenti.

(Thou too, O halved Menander, art placed among the highest and deservedly—lover of pure speech. And I would that to thy mild writings there had been joined comic power, so that thy excellence might have had equal honour with the Greeks and thou be not despised in that part. This one thing, Terence, thou lackest—to my distress and sorrow.) In his own time he appears to have been accused of plagiarism and also of receiving help in writing his plays from his friends—a charge which he several times refers to in his prologues and in that of the *Adelphoe* apparently admits to be true.

In using his Greek models, apart from "contamination" referred to above, he permits himself various liberties. Names are altered, individual scenes remodelled, *e.g., Eunuchus,* 539 *seq.* or abbreviated, cf. *Hecyra,* 825, and new characters, *e.g.,* Charinus and Burria in the Andria, introduced.

The judgment of Caesar already quoted seems to have been

pretty generally endorsed in antiquity. Varro found his chief merit in the exhibition of character (*in ethesin Terentius poscit palman*); Cicero in his choice language.

In another passage—*De optimo genere oratorum*, i.—Cicero speaks of Terence as generically differing from Accius; Horace, *Epist.*, ii. 1.59 quotes as a received opinion that Caecilius (who, according to legend, Sueton *Vit. Ter.*, encouraged the young poet) excelled in dignity, Terence in art. Ovid, *Trist* ii. 359 *seq.* contrasts him with Accius: *Accius esset atrox, conviva Terentius esset.* Quintilian (x. 1.99) says that the Romans make a poor show in comedy . . . "though the writings of Terence are ascribed to Scipio Africanus—writings which in this kind are most elegant and could have been still more pleasing if they had been confined to trimeter lines"—a criticism which seems to refer to some departures in prosody from the strict Menandrian model. According to Servius, Terence is preferred to the other comic poets solely on the ground of propriety, being in other respects inferior. Aulus Gellius, xv. 24 has preserved some lines of Vulcatius Sedigitus, in which the Roman writers of comedy are arranged by him in order of merit, thus—Caecilius, Plautus, Naevius, Licinius, Atilius, Terence, Turpilius, Trabea, Luscius and lastly, added, *causâ antiquitatis*, Ennius. In England and on the Continent, Terence has been popular and influential and imitations of his plays have been numerous, *e.g*, the *Andria* was copied in the *Conscious Lovers* of Sir Richard Steele, the *Heautontimorumenos* in the *All Fools* of Chapman, the *Eunuchus* in Sedley's *Bellamira*, and La Fontaine's *L'Eunuque*, the *Phormio* in Molière's *Les Fourberies de Scapin*, the *Adelphoe* in the same author's *Ecole des Maris*

See *Editio princeps:* Strasbourg (1470); R. Bentley (Cambridge, 1726); Fleckeissen (Leipzig, 1898). Editions of single plays are numerous. (A. W. MA.)

TERENTIANUS, surnamed MAURUS (a native of Mauretania), Latin grammarian and writer on prosody, flourished probably at the end of the 2nd century A D. His references to Septimius Serenus and Alfius Avitus, who belonged to the school of "new poets" (*poetae neoterici* or *novelli*) of the reign of Hadrian and later, seem to show that he was a near contemporary of those writers. He was the author of a hexameter treatise in four books, on letters, syllables, feet and metres, of which considerable use was made by later writers. The most important part of it is that which deals with metres, based on the work of Caesius Bassus

Best edition, by H. Keil, *Grammatici Latini*, vi; with commentary by L. Santen (1825); *see* also Teuffel-Schwabe, *Hist. of Roman Literature* (Eng. tr.), 373*a*.

TERGESTE (mod. *Trieste*, *q.v.*), an ancient city of Istria, 26 m. E S.E. of Aquileia by road, at the northern extremity of the peninsula of Istria, in a bay at the head of the Adriatic Sea. Its importance was in ancient days, as now, mainly due to its commerce as the outlet of Pannonia and Dalmatia. In 33 B.C. Augustus, during his Dalmatian wars, built a wall and towers there, as an inscription records. The cathedral of S. Giusto perhaps occupies the site of the Roman Capitol, or temple of Jupiter, Juno and Minerva, some of the walls and columns of which may be seen in the tower, which dates from 1337.

TERM, in logic, means the subject or predicate of a judgment (or proposition). It is, however, commonly used in a much wider sense so as to include also any word or combination of words that is capable of being used as the subject or predicate of a proposition. Of the different kinds of terms usually distinguished, the following are the most important. (a) *Connotative* terms are those which have a standard (or conventionally fixed) meaning. In this sense practically all terms except proper names are connotative. *Non-connotative* terms have no such fixed meaning. It is usual to restrict this distinction to concrete terms, on merely etymological grounds. (b) *Positive* terms are those which primarily indicate or suggest the presence of something (though indirectly they may also imply the absence of something). *Negative* terms primarily indicate the absence of something (though indirectly, and perhaps rather vaguely, they may also imply the presence of something). (c) *Singular* terms are such as are applicable in the same sense to one object only (or to one group treated as one object). *General* terms are those which can be applied in the same sense to any one of a class (or kind) of objects. (d) *Concrete* terms are those which denote anything that can be regarded as a whole having attributes and standing in various relations, even if it is *not* tangible (*e.g.*, mind, character, logic, as well as table, chair, etc.). *Abstract* terms are the names of some attribute, aspect or relationship considered apart from the things in which it exists (*e.g.*, size, beauty, friendship, etc.). (e) *Relative* terms are those the special function of which it is to draw attention to some definite relationship in which the object named stands to some other object (*e.g.*, husband, wife, partner, etc.). *Absolute* terms are those which have no such special function, although the things named will as a matter of fact stand in all sorts of relationships to other things (*e.g.*, John Smith, table, chair, etc.). Relative terms usually go in pairs, for every relationship requires at least two terms—"parent" and "child," "brother" and "brother" (or "sister"), and so on. (f) *Collective* terms denote groups of similar separate units as groups (*e.g.*, "army," "company," "library," etc.). *Non-collective* (or unitary) terms denote units that are not groups of similar separate units (*e.g.*, "table," "chair," "house," etc.).

Of the above classifications or distinctions the first (a) is mainly concerned with verbal terms or names. The others are primarily concerned with differences in the way in which we think about things, even the same things it may be. Sometimes a thing is regarded in all its individuality (as singular); sometimes as one of a kind (general); sometimes it is considered in relation to something else (relative); sometimes for its own sake (absolute); sometimes we think of what a thing is (positive), and sometimes of what it is not (negative); and so on. (*See* LOGIC and the bibliography given there)

A Term of Years, in English law, is the time during which an interest in an estate for life or for years is enjoyed, also the interest itself, because such an interest must determine at a definite time. If the interest be for life, it is an estate of freehold, if for years, only a personal interest in real estate, and so personalty, even though the length of the term—for instance, 1,000 years—may far exceed in duration any possible life estate. (*See* the Law of Property Act, 1925.) The same act gives power to enlarge the unexpired residue of a term of 200 years in certain cases into the fee simple, and the Places of Worship (Enfranchisement) Act 1920 gives power to enlarge leases for lives or even 21 years.

Terms, in the sense of a limited and certain period of time during which the law courts are open, used to affect only what were called in England the superior courts—that is, the king's bench, common pleas and exchequer.

There were four terms, Hilary, Easter, Trinity, Michaelmas, the average duration of each being about three weeks. By the Judicature Act of 1873 terms were abolished so far as related to the administration of justice and sittings substituted. The dining-terms at the Inns of Court correspond in point of time with the old terms and not with the sittings.

At the University of Cambridge the academic year is divided into three terms, Michaelmas, Lent and Easter; while at the University of Oxford there are four terms in the year, Michaelmas, Hilary, Easter and Trinity School years now generally consist of three terms, divided by Christmas, Easter and Summer holidays, the old half-years having gradually been abolished.

In Algebra, an expression not connected to another expression by the sign $+$ or the sign $-$. For example, ab^2 is a single term (monomial), whereas $a+b^2$ or a^2-ab^2 has two terms (binomial). (*See* POLYNOMIAL.)

TERMINATOR, in astronomy, the bounding line between light and darkness on the apparent disc of the moon or of a planet. At places on the terminator the sun is either rising or setting.

TERMINI IMERESE (anc. *Thermae Himerenses*), a seaport town of Sicily, in the province of Palermo, 23 m. E.S.E. of it by rail. Pop. (1921) 18,639. It is finely situated on a promontory above its harbour; it was founded in 408 B.C. by the Carthaginians, after their destruction of Himera, in the vicinity of hot springs mentioned by Pindar (*Od.* xii. 19) which are still resorted to and are well fitted up (temp. 110° F). Agathocles (*q.v.*) was born here. It was taken by Rome in the First Punic war. A

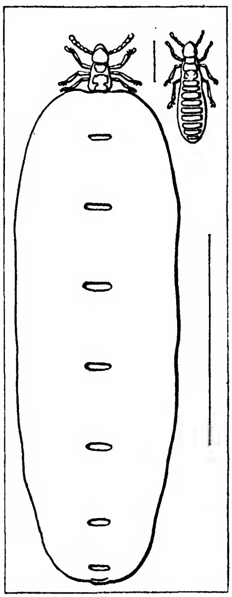
Roman road ran from it to Catana. Scanty remains of buildings of Roman times (baths, an amphitheatre and a so-called curia) exist in the upper part of the town; and outside it on the south are considerable remains of two Roman aqueducts.

TERMINOLOGY: *see* Nomenclature and Terminology.

TERMINUS [Lat. a boundary stone], a stone or post which was set up in the ground with the following religious ceremonies. A hole was dug and a fire lighted; a victim was sacrificed and its blood poured into the hole, together with incense and fruits, honey and wine, and the ashes of the sacrifice. Then the boundary stone, which had been previously anointed and crowned with garlands, was placed upon the hot ashes and fixed in the ground. Any one who removed a boundary stone was accursed (*sacer*) and might be slain with impunity; a fine was afterwards substituted for the death penalty. From this sacred object evolved the god Terminus. On Feb. 23 (the end of the old Roman year) the festival called *Terminalia,* according to Wissowa a festival not of the god but of the boundary stones (*termini*), was held. The owners of adjacent lands assembled at the common boundary stone and garlanded each his own side of the stone. An altar was set up and offerings of cakes, corn, honey and wine were made. Later a lamb or a sucking pig was sacrificed. The proceedings closed with songs to the god and a general merrymaking, in which all the members of the family and the servants took part.

A similar festival was held at the old boundary of the Roman territory between the fifth and sixth milestone on the road to Laurentum. When the Capitoline temple was to be built the auguries forbade the removal of one of these *termini* (a boundary mark of some old precinct?) and it was enclosed within the walls of the new sanctuary, an indication of the immovability of such stones and of the permanence of the Roman territory.

See Wissowa, *Religion und Kultus der Römer* (2nd ed.), p. 136; W. W. Fowler, *The Roman Festivals,* p. 324 (1899).



THE ROYAL PAIR OF TERMES NEMOROSUS, THE LARGER FIGURE BEING THE QUEEN, THE SMALLER THE KING. ONE-QUARTER THE ACTUAL SIZE

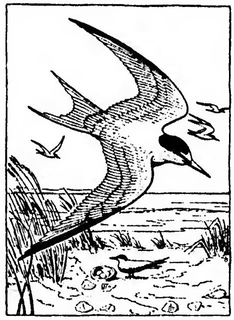
TERMITE, the name given to usually pale-coloured, soft-bodied insects living in large societies below ground or in other concealed situations. These societies consist of wingless, sterile individuals generally of two types —the soldier and the worker— and among them there develop reproductive forms, some of which are wingless, and others are endowed with two pairs of long, narrow, membranous wings. The latter individuals leave the colony in periodic swarms, cast their wings and proceed to establish new colonies. Termites form the scientific order Isoptera (*see* Insects) and are popularly known as white ants; but as they differ fundamentally from true ants and are rarely white, this designation is open to objection. Owing to their gnawing propensities these insects cause immense damage to the woodwork of buildings, and some species attack the roots of growing crops. For further information on termites *see* Social Insects.

TERMITE-PROOF CONSTRUCTION. Damage caused by termites to buildings or their contents can be prevented by proper construction of the buildings and chemical treatment of all wood with coal-tar creosote. Building codes are being revised in many American cities to require termite-proof construction. The best rule is to make the foundations entirely of stone, brick or concrete, including stone or metal columns or pillars in the basement. Basement floors should be of concrete on a gravel base. Where it is impracticable to use these materials all wood near the ground used should be chemically treated. Complete dryness of the foundation and of the basement floors and walls is an important factor. Since subterranean termites can not live or work without access to moist earth, it is only necessary to shut off this source of moisture to prevent damage by this type. Non-subterranean termites can be killed in infested wood by fumigation with hydrocyanic-acid gas.

TERMONDE, a town in the province of East Flanders, Belgium, 25 m. S.W. of Antwerp, at the junction of the Dender and Scheldt. Pop. (1925), 9,648. It was before Termonde that Louis XIV., in 1667, was compelled to retreat through the opening of the dikes. The fortifications were demolished in 1910. The church of Notre Dame contains two fine pictures by Van Dyck, and one masterpiece of Crayer's. The fonts are of the 12th century. The town suffered greatly in the World War, the Hôtel-de-Ville and the church of Notre Dame being much damaged.

TERN, sea birds forming the sub-family *Sterninae* of the gulls (*Laridae*).

The largest British species is the Sandwich tern (*Sterna sandvichensis*), as big as a small gull, with a dark bill tipped with yellow, and dark legs. The common (*S. hirudo*) and Arctic (*S. macrura*) terns are only to be distinguished by the all-red bill of the latter, which is a bolder species with a more northern range, though both breed at Blakeney point in Norfolk. The little tern (*S. albifrois*) is known by its white forehead. *Hydroprogne caspia,* the Caspian tern, is the largest species known, measuring 2ft. in length. In addition to the last three British species, *S. dougalli,* the Roseate tern, is also common to Europe and North America.



BY COURTESY OF THE NATIONAL ASSOCIATION OF AUDUBON SOCIETIES

LEAST TERN (STERNA ANTILLARUM), SHOWING ITS NEST OF EGGS IN THE BACKGROUND

In North America there also occur the noddy (*q.v.*), the sooty tern (*S. fuscata*), and the black tern (*Chlidonias niger*).

Terns breed usually on sand dunes and shingle banks and lay up to four eggs, two being the commonest number, great variation occurring with the season and the locality. They are said by fishermen to damage the fishing, but this has been proved to be a mistake, the birds feeding largely on crustacea, insects and sand eels, which they obtain by plunging into the water from a height of 3–8ft., and emerging with the food in their bills. The male usually feeds the female while she is brooding, often accompanying the presentation with the same play ceremony used in courtship. In the same way, in courtship, food is often presented by the male.

About 75 species are known; the group is cosmopolitan.

TERNATE, the northernmost of the line of islands off the western coast of Halmaheira, Dutch East Indies, which stretch southwards to the Bachian archipelago. It has an area of 25 sq.m., a width of six miles, and consists mainly of a conical volcano 5,600 ft. in height, with three peaks (Arfat, Madina and Kekan), its curious formation being due to many extremely destructive eruptions. Within the last four centuries there has been volcanic activity at Ternate on no less than 70 occasions, the worst recorded being the eruption in 1763, which overwhelmed the thriving little village and Ft. Takomi, which is situated on the north-west coast, and so completely devastated one slope with lava flow that it has since been known as Burnt cape (Batu Angus), whilst two small crater lakes were formed where the village stood. An eruption in 1840 destroyed nearly every house in the town of Ternate, and when A. R. Wallace was there in

1858 he experienced an earthquake and noted the destructive effects of former shocks. The northern half of the island has suffered most from volcanic activity There, lava streams have flowed down the mountain side right to the sea, and there are numerous bare tracts of land, but on the southern and eastern coast there is forest and luxuriant vegetation, with a good deal of cultivated land on the flat strip by the shore; vegetation extends even far up the mountain side Rice and maize are grown, also sago, coffee, pepper, nutmegs and fruit (good mangoes and durians); Ternate was once a leading centre of spice cultivation It now has a population of 18,924, including 580 Europeans and Eurasians, 77 Chinese and 474 Arabs, the native population being of very mixed blood, probably Malay preponderating, but with Papuan elements, having a language of their own, written in the Arabic character, and Mohammedan by religion (also *Crang Seracci* descendants of natives converted to Christianity by the Portuguese) Ternate is of importance as one of the two residences which make up the Government of the Moluccas, Amboyna being the other Ternate residency is composed of the Ternate-Tidore group (13 islands, and the Kayua and Goraityi groups), the Halmaheira group (Gilolo, west Halmaheira, Weda, south, and Tobelo, north and north-eastern Halmaheira, with the island of Morotai), the Bachian and Obi groups, the Sula group (with the State of Banggai, in east Celebes and the Banggai islands), west New Guinea (with the island of Bisol), Sorong (north-west New Guinea, with the islands Waigiu, Salwatti and Battanta), Manokwari (the westerly part of north New Guinea), Yappen (the island of that name, with a strip of the coast of New Guinea from the Mamberano river to the Wapangga), Hollandia (the easterly part of North New Guinea, from the Mamberano river to the boundary between Dutch and British New Guinea), and the Schouten islands (the group of islands of that name). The population of the residency in 1927 was 276,314.

Ternate Town, population 6,374, lies on a flat strip of land on the south side of the island, at the foot of the mountain It is a very picturesque settlement, the houses interspersed amongst a wealth of trees, with the volcano for a background, and, being close to other volcanic islands, one of which, Tidore, is so close that it helps to form the fine harbour of Ternate, and to the coast of Halmaheira, it has magnificent views The port, which possesses piers and a coaling jetty, is a regular place of call for vessels of the Royal Packet Navigation company, affording frequent communication with Celebes, Amboyna and New Guinea.

Although it is the headquarters of a residency, Ternate has now only the shadow of its former greatness Its trade is small (chiefly copra and nutmegs), its sultan is a pensioner of the Dutch Government and many of its inhabitants live by his bounty on his lands

History.—Ternate became known to Europe through the Portuguese, who settled there in 1521, and made it one of their chief spice-collecting centres. Conflict with the sultan, or king, as he was styled then, who objected to the establishment of a Portuguese spice monopoly, led to the expulsion of the Portuguese from the island in 1581 In the meantime, in 1579, Sir Francis Drake had called at Ternate, being received favourably by the king, and allowed to ship between four and five tons of cloves, but the visit was never followed up. Drake was much impressed with the wealth and state of the king of Ternate, and wrote, of his visit to the monarch. "The King had a very rich canopy with embossings of gold borne over him, and was guarded with twelve lances From the waist to the ground was all cloth of gold, and that very rich; in the attire of his head were finely wreathed diverse rings of plaited gold, of an inch or more in breadth, which made a fair and princely show, somewhat resembling a crown in form; about his neck he had a chain of perfect gold, the links very great and one fold double; on his left hand was a diamond, an emerald, a ruby, and a turky (turquoise); on his right hand in one ring, a big and perfect turky, and in another ring many diamonds of a smaller size."

When the Dutch visited Ternate, at the beginning of the 17th century, the sultan, who was anxious to extend his power over the Moluccan islands generally, and even over a part of Celebes, arranged to give the Dutch a spice monopoly for their assistance against the Spaniards and Portuguese (Portugal had become incorporated with Spain and the Spaniards had reconquered Ternate). So Ternate rose to power and made many of the Moluccan islands, the eastern and northern part of Celebes and Buton suzerain, but the Dutch bolstered up the power of Ternate only so long as suited their purpose, and when, in their efforts to confine Moluccan spice cultivation to cloves in Amboyna and nutmegs in the Banda islands, they destroyed ruthlessly the spice gardens of the northern Moluccas, Ternate included, causing Ternate to revolt, an example which was followed in neighbouring islands. They found it convenient (in 1683), to declare all contracts with Ternate void, and the chiefs who had looked to Ternate as their suzerain were informed that henceforth they would hold their lands directly from the Dutch. Since that time, although the power of the sultan of Ternate as their vassal, has been recognized by the Dutch nominally, and he has certain privileges regarding the native population, the executive, in Ternate, and throughout the lands of the Residency, remains in Dutch hands

See A. R. Wallace, *The Malay Archipelago* (London, 1890).

(E. E. L.)

TERNE-PLATE: *see* TIN-PLATE AND TERNE-PLATE.

TERNI (anc. *Interamna Nahars*), a town, episcopal see, and capital of a province of Umbria, Italy, situated among the Apennines, 426 ft. above sea-level, in the valley of the Nera (anc. *Nar*), from which the town took its distinguishing epithet, 5 m below its junction with the Velino, and 70 m N by E of Rome by rail. Pop (1921) 27,893 (town), 36,324 (commune) It has important iron and steel works and iron foundries, at which armour-plates, guns and projectiles are made for the Italian navy, also steel castings, machinery and rails, a royal arms factory, a large jute factory, a carbide factory, a wool spinnery, etc, and lignite mining Terni lies on the main railway line from Rome to Foligno and Ancona, and is the junction for Rieti and Sulmona. Its most interesting buildings are the cathedral (restored in 1653 with remains of the earlier 13th century façade and an early crypt), and the Romanesque churches of S Pietro and S. Francesco Its antiquities include traces of the city walls of rectangular blocks of travertine incorporated in the well-preserved mediaeval walls, remains of an amphitheatre, a temple, now the round church of S Salvatore, theatre and baths (?), and numerous inscriptions Five miles to the east are the falls of the Velino (*Cascate delle Marmore*), which took a very high place among European waterfalls; the cataract has a total descent of about 650 ft., in three leaps of 65, 330 and 190 ft, respectively They owe their origin to M' Curius Dentatus, who in 272 B C first opened an artificial channel by which the greater part of the Lacus Velinus in the valley below Reate was drained. They supply the motive power for the factories of the town and have lost much of their former beauty

Terni is the ancient *Interamna* (*inter amnes*, "between the rivers," *i e.* the Nar and one of its branches), originally belonging to Umbria, and founded, according to tradition in the year 672 B.C. The recent discovery of a neolithic village, and of cemeteries of the Villanovan period, with numerous inhumation graves of Picenes of 1200–1000 B C. (*see* Randall MacIver, *Iron Age in Italy,* 1927, 140–144) shows that the site was occupied much earlier It is first mentioned in history as being, along with Spoletium, Praeneste and Florentia, portioned out among his soldiers by Sulla. During most of the middle ages and up till 1860 Terni was subject to the popes. It was the scene of the defeat of the Neapolitans by the French on November 27, 1798.

TERPANDER, of Antissa in Lesbos, Greek poet and musician About the time of the Second Messenian war, he settled in Sparta, whither, according to some accounts, he had been summoned by command of the Delphian oracle, to compose the differences which had arisen between different classes in the state. He is regarded as the real founder of Greek classical music, and of lyric poetry; but as to his innovations in music our information is imperfect. According to Strabo (xiii. p 618) he increased the number of strings in the lyre from four to seven; others take the fragment of Terpander on which Strabo bases his statement (Bergk, 5) to mean that he developed the citharoedic nomos

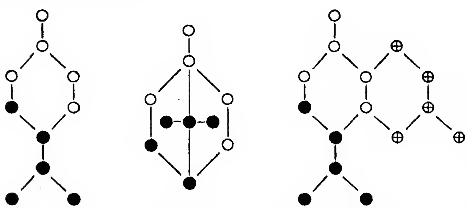
(sung to the accompaniment of the cithara or lyre) by making the divisions of the ode seven instead of four.

Fragments (the genuineness of which is doubtful) in T. Bergk, *Poetae Lyrici Graeci*, iii.; *see* also O. Löwe, *De Terpandri Lesbii aetate* (1869), who places him about 676 B.C.

TERPENES, in chemistry, is the generic name of a number of unsaturated cyclic hydrocarbons, which are usually classified in three groups: terpenes proper, $C_{10}H_{16}$: sesquiterpenes, $C_{15}H_{24}$: and polyterpenes, $(C_5H_8)_n$. Sometimes hemiterpenes, C_5H_8, and also a series of so-called olefinic terpenes are included, but the latter are all open-chain compounds. (*See* CHEMISTRY: *Organic.*) Many terpenes and sesquiterpenes are widely distributed as constituents of essential oils, particularly of those secreted by plants belonging to the families *Coniferae* and *Myrtaceae* and the genus *Citrus.* The essential or fragrant oils occur usually in the flowers, fruit, leaves and stems, and sometimes in the roots and seeds of the plants, and differ from the fatty oils, found generally in the seeds, by their volatility in a current of steam. The majority contain a complex mixture of ingredients, but some are composed mainly of one constituent, as, for example, oil of turpentine which is chiefly pinene. In essential oils the terpenic hydrocarbons are commonly accompanied by products which usually are either alcohols or ketones and are often of greater importance as perfumes or as medicinal agents than the associated terpenes.

The hemiterpene *isoprene* $CH_2{:}C(CH_3)-CH=CH_2$, is related to the terpenes in several ways. Thus it can be obtained by heating the vapours of limonene or pinene to a high temperature, and on the other hand when isoprene is heated to 300° C in a sealed tube two molecules unite to form one molecule of dipentene, $C_{10}H_{16}$. (*See* POLYMERIZATION.) Theoretically the carbon skeletons of the terpenes proper may be built up from two, and those of the sesquiterpenes from three isoprene nuclei

as illustrated below:

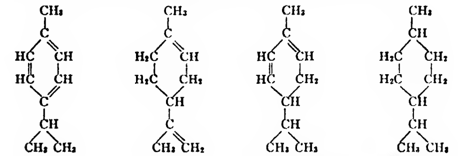


Monocyclic terpene nucleus — Bicyclic terpene nucleus — Sesquiterpene nucleus

TERPENES PROPER

Most of the terpenes proper which occur naturally are colourless highly refractive fragrant liquids, of lower density than water; camphene and bornylene (the latter is a synthetic laboratory product) are crystalline solids of low melting points. They usually boil between 150° and 180° C and are readily volatile in steam. They are practically insoluble in water but dissolve freely in alcohol, ether and other organic solvents. Chemically very active, they tend to resinify by aerial oxidation and are easily attacked even by mild oxidizing agents, such as a dilute solution of potassium permanganate. They unite with hydrogen chloride, bromine, nitrosyl chloride, ozone, etc., forming additive compounds, and some at least are easily converted into isomerides in presence of acids. (*See* ISOMERISM.) Most of the naturally occurring terpenes are optically active, some being dextro- and others laevo-rotatory (*d*- and *l*-forms); optically inactive (*dl*-) modifications are also known.

The terpenes proper are classified in three groups: (1) monocyclic terpenes, which unite with two molecules of halogens or halogen acids to form compounds such as $C_{10}H_{16}Br_4$ and $C_{10}H_{18}Cl_2$; (2) bicyclic terpenes, which combine with only one molecule of a halogen or halogen acid to form compounds such as $C_{10}H_{16}Br_2$ and $C_{10}H_{17}Cl$; and (3) tricyclic terpenes, which do not form additive compounds. Structurally, most of the monocyclic terpenes or *menthadienes* are related to the aromatic hydrocarbon cymene on the one hand and the cycloparaffin menthane on the other.



Cymene, $C_{10}H_{14}$ — Limonene, $C_{10}H_{16}$ — α-Phellandrene, $C_{10}H_{16}$ — Menthane, $C_{10}H_{20}$

Thus such terpenes as limonene or α-phellandrene could be produced theoretically by the removal of two pairs of hydrogen atoms from menthane, and similarly the bicyclic and tricyclic terpenes could also be derived from menthane or an isomeride by withdrawal of two pairs of hydrogen atoms and resultant formation of "bridged rings." These bridges are distinguished by numbers denoting the number of carbon atoms contained in them, the direct union of the two tertiary carbon atoms being designated as O; if one carbon atom intervenes, then the number I is used, and so on. Thus three numbers serve as the "characteristic" of the compound. Hydrocarbons of this class with five atoms of carbon are termed "bicyclopentanes," with six atoms of carbon "bicyclohexanes," etc.

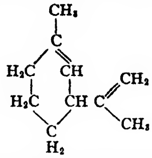
Monocyclic Terpenes.—Among the monocyclic terpenes one of the most widely distributed in essential oils is *limonene,* which appears to have been known in the 16th century, if not earlier. The dextro-rotatory form is best obtained by fractional distillation of bitter-orange oil, of which it forms the main constituent; it also occurs in oils of lemon, bergamot, caraway, etc.; the *l*-form is likewise found in nature, although not so commonly. The optically inactive or *dl*-form, likewise known as *dipentene,* is a constituent, frequently accompanied by other terpenes, of a large number of essential oils, and is also formed from other terpenes and polyterpenes at high temperatures. Thus the active limonenes and also pinene are converted into dipentene at 250°–270° C, and several oxygenated compounds of the terpene group, such as terpin hydrate and terpineol, easily yield it by loss of the elements of water when warmed with dehydrating agents. Moreover, it is one of the products of the destructive distillation of rubber, gutta percha and many resins. When warmed with alcoholic sulphuric acid it yields terpinene, whilst concentrated sulphuric acid or phosphorus pentasulphide convert it into paracymene. The constitution of dipentene was definitely established in 1904 when W. H. Perkin, jun., effected its synthesis—the first instance of the synthesis of any of the naturally occurring terpenes.

Limonene, a colourless fragrant liquid, boils at 175–176° C; it forms a characteristic crystalline tetrabromide, $C_{10}H_{16}Br_4$, and by the action of nitrosyl chloride is converted into a mixture of two stereoisomeric crystalline nitrosochlorides, $(C_{10}H_{16}{\cdot}NOCl)_2$, which can be separated by treatment with ether, in which the α-form is readily, and the β-form only sparingly, soluble. (*See* STEREOCHEMISTRY.)

Another monocyclic terpene widely distributed in nature is *α-phellandrene.* The laevo-rotatory modification is found in the essential oils of many species of eucalyptus, whilst the *d*-form occurs in bitter fennel oil, etc. This terpene, which has also been synthesized, is very unstable; it undergoes polymerization (*q.v.*) if distilled at the ordinary pressure and must therefore be fractionated in a vacuum, and by the action even of dilute acids it is converted into isomeric terpenes such as dipentene and terpinene. It does not yield solid compounds either with bromine or with hydrogen chloride, the only well-characterized crystalline derivative being the nitrosite $C_{10}H_{16}N_2O_3$, or rather the mixture of stereoisomeric nitrosites, obtained by the action of nitrous acid on the hydrocarbon. From these nitrosites phellandrene cannot be regenerated.

Sylvestrene is of interest as the only menthadiene of the *meta*

series which has been found in natural products. As the formula shows, its constitution is similar to that of limonene except as regards the relative positions of the $-CH_3$ and $-C(CH_3):CH_2$



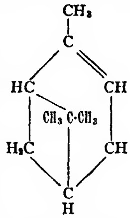
groups in the molecule. The dextro-rotatory form of sylvestrene is a constituent of Swedish and Russian oil of turpentine (from *Pinus silvestris*), and is best obtained in the pure state by heating its hydrochloride with aniline or with sodium acetate and acetic acid; these are general methods for the regeneration of terpenes from their hydrochlorides It also is a colourless fragrant liquid, which boils at 176°–177° C Unlike phellandrene, it is relatively a stable substance, not being easily converted into isomeric terpenes by heat or by the action of acids. An intense blue colour is developed if a drop of concentrated sulphuric acid is added to a solution of sylvestrene in acetic acid. A finely crystalline dihydrochloride $C_{10}H_{18}Cl_2$ is produced by the action of hydrogen chloride on sylvestrene; the tetrabromide $C_{10}H_{16}Br_4$ and the nitrosochloride $C_{10}H_{16}{\cdot}NOCl$ are also crystalline solids The inactive (*dl-*) form, formerly known as carvestrene, has been synthesized by W. H Perkin

Of all the monocyclic terpenes *terpinene* is the most stable towards dilute mineral acids, and consequently is frequently produced by the intramolecular rearrangement of other less stable terpenes such as pinene, limonene and phellandrene, as well as from terpineol, cineole, etc , under the influence of these reagents It is said to occur in cardamom oil, and is characterized by its crystalline nitrosite $C_{10}H_{16}{\cdot}N_2O_3$, m p. 155° C.

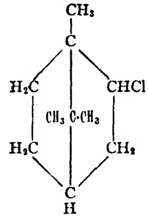
Terpinolene, produced along with terpinene and dipentene by the action of dilute acids on pinene, cineole, and terpineol, does not occur in nature It is unstable, and easily converted into terpinene.

Bicyclic Terpenes.—The most familiar member of this group of hydrocarbons is *pinene,* which is the chief constituent of a large number of essential oils; the dextro-rotatory modification (australene) is found in many of the eucalyptus oils, and in the oils of fennel, rosemary, carrot, etc ; the laevo-form (terebenthene) is contained in oils of lemon, lavender, etc., and the inactive (*dl-*) form also occurs naturally. The chief source, however, is oil of turpentine The oleo-resin known as turpentine, which exudes from various species of *Pinus,* when distilled in steam yields oil of turpentine, which volatilizes with the steam, and a non-volatile residue called rosin or colophony. French turpentine oil is laevo-rotatory, whilst the American and Burmese oils are dextro-rotatory, the turpentine from which these oils are distilled being obtained from different species of *Pinus; d*-pinene is also found in Russian, Swedish and German oils. Oil of turpentine is a solvent for resins, rubber, sulphur, phosphorus, etc., and is largely used in making varnishes and oil paints. When exposed to air it gradually darkens and resinifies through absorption of oxygen. Hydrogen peroxide and apparently ozone are produced during the process, so that by shaking oil of turpentine with warm water and air a solution results having disinfecting and deodorizing properties.

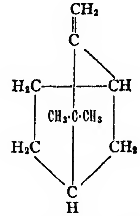
Pure pinene, prepared by heating its nitrosochloride with aniline, is a colourless aromatic liquid which boils at 156°–157° C. It very easily undergoes transformation into isomeric terpenes, for example, into dipentene when heated to 250°–270°, into terpinolene and terpinene when treated with alcoholic sulphuric acid, and into dipentene (or its derivative terpin hydrate) by the action of dilute sulphuric or nitric acids, whilst many other acids convert it into esters of the alcohol borneol. The crystalline nitrosochloride, $C_{10}H_{16}{\cdot}NOCl$, produced by the action of nitrosyl chloride, is on the other hand a true derivative of pinene, and is notable as being the only derivative from which the hydrocarbon can be regenerated With hydrogen chloride it unites to form a crystalline compound $C_{10}H_{17}Cl$, the so-called pinene hydrochloride, which is very volatile, even at the ordinary temperature, and can be distilled with little or no decomposition. This substance, which resembles camphor in its odour and volatility, has been known for long as "artificial camphor," but must not be confused with synthetic camphor, which chemically is identical with the product obtained from natural sources Pinene hydrochloride, however, is not a derivative of pinene, being in fact bornyl chloride; when heated with sodium acetate and acetic acid it yields not pinene but the isomeric terpene, camphene.



α-Pinene, $C_{10}H_{16}$



Bornyl chloride, $C_{10}H_{17}Cl$



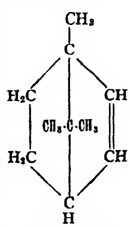
Camphene, $C_{10}H_{16}$

Both borneol and camphene are readily oxidized to camphor, and thus methods of obtaining camphor from pinene have been developed

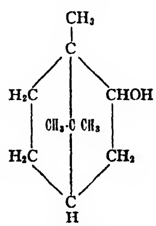
Pinene is easily attacked by various oxidizing agents, yielding many different products among which may be mentioned the finely crystalline compound, terpin hydrate, which is easily converted by loss of the elements of water into an unsaturated alcohol, α-terpineol, the chief product of the oxidation of pinene with hydrogen peroxide Ordinary or α-pinene contains a small proportion of an isomeric terpene known as β-pinene.

As stated above, attempts to regenerate pinene from the so-called pinene hydrochloride, by the usual methods, result in the production of *camphene* This terpene can also be obtained from borneol by heating it with dilute sulphuric acid, or with potassium bisulphate at 200°. It has been found in some varieties of oil of turpentine; the *d*-form occurs in oil of ginger, etc , and the *l*-form in citronella oil and other essential oils. It differs from most of the other bicyclic terpenes in being a crystalline solid, which melts at 51° and can be distilled unchanged It is relatively stable, not being readily transformed into other terpenes, but like all these hydrocarbons is easily oxidized When chromic acid is used as the oxidizing agent the product is camphor, which can thus be obtained from pinene. With hydrogen chloride it yields the crystalline hydrochloride $C_{10}H_{17}Cl$, and when warmed with acetic acid and dilute sulphuric acid is converted into the acetate of isoborneol, $C_{10}H_{17}OH$, an alcohol which appears to be a stereo-isomeride of borneol.

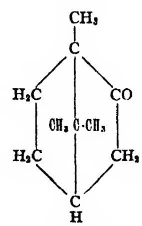
Another solid terpene, *bornylene,* although apparently not occurring in any essential oil, is interesting on account of its relationship to borneol and camphor As the formulae show, the structure of the carbon skeleton is the same in all these compounds:



Bornylene



Borneol



Camphor

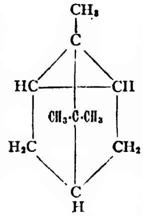
Pinene unites with hydrogen iodide to form bornyl iodide, and this in turn yields bornylene when heated with alcoholic potash at 170° C. The latter is best prepared by converting borneol into

bornyl methyl xanthate, $C_{10}H_{17}O{\cdot}CS{\cdot}SCH_3$, which when heated so decomposes that bornylene is produced. This decomposition is an excellent method for the preparation of terpenes from the corresponding alcohols.

Bornylene resembles camphene in appearance, but has a much higher melting point, 113°; it sublimes easily and its extreme volatility soon disappears if exposed to air at the ordinary temperature.

Among other bicyclic terpenes may be mentioned *sabinene*, a liquid, of which the *d*-form, along with the related alcohol sabinol, is a constituent of oil of savin; *carene*, which occurs in the oil of *Pinus longifolia;* the *fenchenes*, liquids which do not occur naturally but have been prepared from *d*- and *l*-fenchones, ketones which are found in fennel oil and thuja oil; and the *thujenes* which also are not natural products but have been prepared from the ketones α- and β-thujone (tanacetone) which occur in a number of essential oils.

Tricyclic Terpenes.—Under certain conditions a crystalline compound of the formula $C_{10}H_{16}Br_2$ is obtained by the action of bromine on pinene. When this so-called pinene dibromide is heated with zinc dust and alcohol a terpene known as *tricyclene* is obtained. This terpene, usually found in small quantities in specimens of camphene, is a crystalline solid, which melts at 67·5° C, and boils at 153° C. It is not capable of forming additive compounds with halogen acids, etc., and is regarded as having the formula shown at the right.

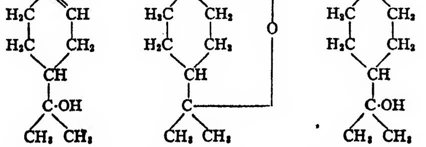


Oxygenated Derivatives.—Certain of the oxygenated derivatives of the terpenes already mentioned deserve further notice.

α-Terpineol, $C_{10}H_{17}OH$, found in a number of essential oils, can also be obtained by treatment of dipentene dihydrochloride with dilute aqueous caustic potash, by dehydration of terpin hydrate, or by oxidation of pinene with hydrogen peroxide. It usually occurs, mixed with smaller proportions of isomeric alcohols, as a thick oily liquid with a pleasant odour, but in the pure state is a crystalline solid of low melting point (37° C) and finds uses in perfumery and as a mild antiseptic. It is easily converted into terpenes by loss of the elements of water, yielding according to the conditions, dipentene, terpinene or terpinolene, and it can also be converted into cineole by warming with phosphoric acid.

Cineole, $C_{10}H_{18}O$, occurs in oils of wormseed, cardamom, etc., and also in many eucalyptus oils, and is separated by cooling the appropriate fraction of the oil; it can also be obtained by shaking terpin hydrate with dilute sulphuric acid. It is a colourless liquid which solidifies at 1° C and boils at 177°, and has a characteristic eucalyptus odour. With phosphoric acid, hydrobromic acid and some other substances it forms crystalline additive compounds. It finds considerable use in medicine on account of its mild antiseptic properties. Chemically it may be regarded as an oxide derived from the dihydric alcohol *Terpin,* $C_{10}H_{18}(OH)_2$.

Terpin hydrate, $C_{10}H_{18}(OH)_2{\cdot}H_2O$, best prepared by the action of dilute nitric acid on an alcoholic solution of pinene, forms beautiful crystals, and when heated is converted into terpin (the *cis*-form), which is also a solid, m.p. 105° C. The relationship of these compounds is shown by the following formulae:



α-Terpineol Cineole Terpin

Borneol **or "Borneo Camphor,"** $C_{10}H_{17}OH$, **occurs, in the dextro**rotatory form, in *Dryobalanops camphora*, a tree which grows in Borneo and Sumatra, and the *l*-form likewise is found in a number of essential oils. It can be prepared by the reduction of camphor, *e.g.*, with sodium and alcohol, in admixture with its stereoisomeride, *iso*borneol. It crystallizes in large colourless plates which melt at 208° C and can be distilled without change. Chromic acid oxidizes it to camphor, the *d*- and *l*-forms yielding *d*- or *l*-camphor respectively.

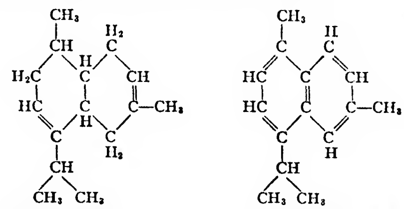
Camphor, or Japan camphor, $C_{10}H_{16}O$, is dealt with in a separate article, together with menthene and menthol. (*See* CAMPHORS.)

Piperitone (*q.v.*), also $C_{10}H_{16}O$, is of importance as being a large constituent (up to nearly 50%) of the oil of several species of eucalyptus.

SESQUITERPENES, $C_{15}H_{24}$

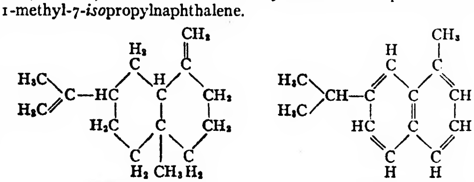
Sesquiterpenes and also sesquiterpene alcohols, $C_{15}H_{25}OH$, are found in many essential oils. A very large number have been described but many have not been fully characterized.

Most of the sesquiterpenes are liquids, specifically lighter than water, with boiling points between 250° and 280° C, and usually with a more or less agreeable odour. They are more viscous than the terpenes proper, and are sparingly soluble in alcohol. Like the terpenes, they resinify easily on exposure to air, form additive compounds with the halogens, the halogen acids, nitrosyl chloride, etc., and in some cases can be directly converted into the corresponding alcohols. At least two groups of sesquiterpenes are known; (1) those which unite additively with two molecules of halogen acids, and which therefore are considered to be bicyclic in structure, and (2) the tricyclic sesquiterpenes, which will not combine with more than one molecule of a halogen acid. On the principle that the carbon skeleton of these hydrocarbons may be divided theoretically into three isoprene units, Otto Wallach suggested that there might be a relationship between the sesquiterpenes and derivatives of naphthalene somewhat similar to that existing between the terpenes proper and derivatives of benzene, and nearly 30 years later Leopold Ruzicka proved the correctness of this speculation, for on dehydrogenating a number of sesquiterpenes and sesquiterpene alcohols by heating them with sulphur he obtained one or other of two derivatives of naphthalene. Most of those examined in this way gave the same hydrocarbon, $C_{15}H_{18}$, named *"cadalene,"* and this was proved by synthesis to be 4:7-dimethyl-isopropylnaphthalene. The relationship between a sesquiterpene and cadalene may be illustrated thus:



Cadinene, $C_{15}H_{24}$ Cadalene, $C_{15}H_{18}$

On the other hand, a second series of sesquiterpenes, and related alcohols, *e.g.*, selinene and the alcohol eudesmol, have been found to yield on dehydrogenation a different hydrocarbon "eudalene," $C_{14}H_{16}$, which has also been synthesized and proved to be 1-methyl-7-*iso*propylnaphthalene.



Selinene, $C_{15}H_{24}$ Eudalene, $C_{14}H_{16}$

Among the sesquiterpenes which have been investigated the fol-

lowing may be mentioned. The laevo-rotatory form of *cadinene* is widely distributed in oil of cade, oil of cubebs and many other essential oils; the *d*-form apparently does not occur in nature. Cadinene is obtained in a pure state from its crystalline dihydrochloride, $C_{15}H_{26}Cl_2$, m.p. 117–118° C, by heating it with aniline. It boils at 274–275°. The alcohol cadinol, $C_{15}H_{25}OH$, is found in galbanum oil, etc., and on dehydration gives cadinene.

Caryophyllene occurs in carnation oil and copaiba oil and can be obtained in a pure state, although with some difficulty, from its dihydrochloride. Its boiling point is 259–261° C. The dihydrochloride forms crystals which melt at 69–70°; the nitrosochloride and the nitrosites (α and β) are also crystalline. When warmed with acetic acid and dilute sulphuric acid caryophyllene is converted into caryophyllene alcohol, $C_{15}H_{26}OH$, which crystallises in colourless almost inodorous prisms. When this alcohol is heated with the usual dehydrating agents, caryophyllene is not regenerated, but an isomeric sesquiterpene *clovene*, a liquid which boils at 261–263° C; the same result follows when caryophyllene dihydrochloride is heated with sodium acetate and acetic acid. Clovene will only unite with one molecule of hydrogen chloride, and is considered to be a tricyclic sesquiterpene. It has not been found in any essential oil.

Other naturally occurring sesquiterpenes are santalene, from sandal-wood oil, cedrene from cedar-wood oil, humulene from oil of hops, selinene from oil of celery-seed and zingiberene from ginger oil, the last being a monocyclic sesquiterpene.

Sesquiterpene Alcohols, $C_{15}H_{25}OH$ —These are found widely distributed and in large numbers in many essential oils Many of them are oily liquids with high boiling points, *e.g.*, cadinol from cade oil, eudesmol from eucalyptus oils, calamenol from calamus-root oil, and cedrol from oil of cedar, whilst others are crystalline solids, for instance, "cubeb camphor" from cubeb oil and "patchouli camphor" from patchouli oil. These alcohols when heated with dehydrating agents are usually converted into the corresponding sesquiterpenes which, however, have not hitherto been observed in natural products.

POLYTERPENES

Diterpenes, $C_{20}H_{32}$, are found in resins and balsams, but hitherto have not been much investigated. They are generally obtained in the form of viscous oils, which usually boil at temperatures above 300° C, and although unsaturated do not readily form crystalline additive compounds. Such substances are *copaivene*, which has been separated from copaiba balsam, and *colophene*, obtained by distillation of colophony and by treatment of pinene with concentrated sulphuric acid; the latter is a thick yellow oil, boiling at 318–320° C. A liquid diterpene (b p. 168°–169° C under 10 mm. pressure) has been obtained along with camphene by heating borneol with zinc chloride.

Triterpenes, $C_{30}H_{48}$.—The *amyrilenes*, obtained by dehydration of the crystalline alcohols α- and β-amyrin, $C_{30}H_{49}OH$, which are found in elemi resin, crystallize well from ether or benzene, but are sparingly soluble in alcohol. They cannot be distilled at the ordinary pressure without decomposition.

A *tetraterpene,* $C_{40}H_{64}$, has been produced by shaking oil of turpentine with antimony trichloride. This *tetraterebenthene* is an amorphous solid, as also is its dihydrochloride, $C_{40}H_{64}{\cdot}2HCl$, and it decomposes when distilled.

Synthetic Rubber.—In 1892 Sir Wm. Tilden observed that a specimen of isoprene which had been kept for some time in a sealed tube had polymerized to form a substance almost indistinguishable, so far as physical properties are concerned, from rubber, and like the natural product capable of vulcanization. It was later discovered that this production of a synthetic rubber from isoprene took place much more rapidly in presence of metallic sodium, which appeared to act as a catalyst. Heating isoprene with acetic acid and other chemical agents also has the effect of producing a form of rubber. Moreover other unsaturated hydrocarbons of the isoprene series polymerize to yield rubber-like substances. These synthetic rubbers have been classified in two groups—the "normal" rubbers obtained by heating isoprene and other related hydrocarbons alone or with acetic acid, and the "sodium" rubbers prepared by the action of that metal on the hydrocarbons. The two series exhibit various differences, and apparently are not chemically identical.

These observations have led to the development of methods for the production of synthetic rubber, which may ultimately compete with the natural product, if its physical and mechanical qualities prove satisfactory and if it can be produced at a sufficiently low cost.

TERRACE CULTIVATION: *see* AGRICULTURE, PRIMITIVE.

TERRACINA, a town and episcopal see of the province of Rome, Italy, 63 m. S.E. of Rome by rail (56 by the Via Appia), 40 ft. above sea-level. Pop. (1921) 9,780 (town), 12,555 (commune). Its position, at the point where the Volscian hills reach the coast, leaving no space for passage between them and the sea, commanding the Pomptine marshes and possessing a small harbour, was one of great strategic importance. It appears in 509 B.C. under Roman supremacy. In 406 it was stormed by the Romans, unsuccessfully attacked by the Volscians in 397, and finally secured in 329 B.C. The construction of the Via Appia in 312 B C. added to its importance: the road at first crossed the hill at the back of the promontory (748 ft.) by a steep ascent and descent, which had its strategic advantages. It was not until the imperial period (probably under Trajan) that a cutting in the rocks at the foot of the promontory (Pisco Montano) finally solved the problem. The depth of the cutting is indicated by marks on the vertical wall at intervals of 10 Roman ft.—figures enclosed in large swallow-tail tablets—the lowest mark, 3 or 4 ft. above the present road, is CXX.

The construction of the Via Severiana, from Ostia to Terracina, added to the importance of the place; and the beauty of the promontory with its luxuriant flora and attractive view had made it frequented by the Romans as early as 200 B.C Galba and Domitian possessed country houses here It appears in the history of the Gothic wars, and Theodoric is said to have had a palace here. It was sacked in 409 and 595. In 872 John VIII. brought it under the domination of the Holy See.

The picturesque modern town occupies the site of the old; the present piazza is the ancient Forum, and its pavement of slabs of travertine with the inscription "A. Aemilius A. F," in letters once filled in with bronze, is well preserved. It is supported by massive arched substructures, which extend under the surrounding houses. The cathedral of SS Pietro e Cesareo, fronting upon it, is ensconced in a temple of Rome and Augustus. The vestibule, in the Cosmatesque style, is supported by ten ancient columns resting upon recumbent lions, with a mosaic frieze upon them. The interior has a fine Cosmatesque pulpit supported by ancient columns resting on lions, a Paschal candlestick of 1245, and a good pavement of the same period with beasts and dragons. There are remains of the town wall in the "polygonal" style, and also part of a later enceinte (4th [?] cent. A.D.) with towers.

The summit is occupied by a massive terrace, supported by arcades of fine *opus incertum* commanding a magnificent view seaward over the coast and over the Pomptine Marshes. On the terrace stood a temple of the early imperial period, 110 by 65 ft., probably of Jupiter Anxur, worshipped as a child. The lower town by the harbour had buildings of some importance (amphitheatre, baths, etc.), of the imperial period. Of the ancient harbour constructed by Antoninus Pius some remains exist.

Near the amphitheatre was found the famous statue of Sophocles now in the Lateran museum. The ancient aqueduct, bringing water some 35 m. from the slopes of the Volscian hills, has been repaired and is in use. Three miles to the north-west, at the foot of the Monte Leano, was the shrine of the nymph Feronia, where the canal following the Via Appia through the marshes ended. Along these 3 m. are numerous ancient tombs.

ARCHAIC TERRA COTTA FIGURINES

1. Statuette of a human figure, modelled in a flat rectangular slab. Greek, 2000 B.C. 2. Greek statuette of a nude female figure holding fluttering bird, 1500–1200 B.C. 3. Painted statuette of a lady. Cretan, 1800–1600 B.C. 4. Greek Archaic statuette of a seated goddess. 5. Modelling of Persephone (Rhodes). 6. Statuette of draped woman. Greek, 4th–2nd cent. B.C. 7. Woman in chair. Greek, 4th–3rd cent. B.C. 8. Woman standing. Greek, 4th cent. B.C. or later. 9. Classical antique. 10. Classical forgery. 11. Statuette of Greek actor, from an Athenian grave. Greek, 4th cent. B.C. 12. Figurine, showing nurse holding a child. Greek, 4th cent. B.C. 13. A mould of a girl, her right hand holding a rabbit, her left patting a dog's head

TERRA-COTTA. The making of figures, bowls and vases of baked clay is one of the most primitive of the arts and has always been carried to a point rivalling all other arts in technical skill and finesse. Various prehistoric figures indicate a high degree of artistry and an excellent conception of the fundamentals of aesthetic appeal. Equal to the ancient cave paintings in vigour, movement and sureness of drawing, is a group of bison found in the cave of Tuc d'Audouberte, and there is no doubt but that terra-cotta was a widely used art at that period.

Pre-dynastic Egyptian figures, often showing indications of painting in brilliant colours, have been found decorated with designs. Melon-shaped vases, with a small foot and slightly flaring mouth, provided on their shoulders with cylindrical handles, have also been discovered. These vases are sometimes decorated with paintings of flora and fauna as well as some of the details of the life of these primitive inhabitants. In Assyria and Persia the art of making tiles (*see* TILE) was developed to a high point at a very early period and such beautiful friezes as those found at Susa, showing animals and warriors in rich browns, yellows and greenish blues, prove this early mastery. In China a recent discovery in the Province of Kansu brought to light a number of finely potted vases showing the utmost sureness of line and decorated with flowing curved conventional motives which probably date about 3000 B.C. and which undoubtedly formed the basis of design of bronzes of the Chow dynasty. So well made are these vases that there is no possible doubt but that terra-cotta had been made hundreds of years prior to this date.

In the invention of glaze it seems to be an established fact that the Near East antedated the Far East and this was possibly due to the discovery that Near Eastern clay made a lighter and more porous pottery. It was also discovered at a very early period that the glaze corrected this fault, and thus began the development of glaze.

Little is known concerning the early uses of terra-cotta in Central and South America, but primitive pottery is found in Guatemala in the form of vases, human figures and groups. The modelling, though lacking in perspective and anatomy, is often beautiful in design, and there seems no doubt but that this Mayan civilization had carried on the art from ancient times. In Peru the sculptural decoration is scarcer; the vases themselves are often made in human form.

But we are concerned in this article mainly with that more specific meaning of the term "terra-cotta" indicating modelled and usually unglazed figures. Among the most beautiful discoveries on the site of Carthage have been the funerary masks, figurines and even masks made for actual use; these show strong Grecian feeling, and yet have faces and figures which are Semitic in character. A large collection of Punic figures was discovered ten years ago at the old Carthaginian cemetery at Iviza.

Other interesting developments of the art were found at Knossos. Among these were the faience figures of pre-Hellenic priestesses with tightly corseted waists, bare breasts and flounced skirts, in whose hands writhed snakes. Some of these figures show a remarkable modelling, as do the small marine objects, found on the same site, with their true-to-life and decorative beauty. The vases, too, which were of unglazed earth decorated with a yellowish ochre colour and a darker earth colour, show a remarkable sense of design and proportion in structure as well as beauty of line. Some of these vases were modelled with relief designs and then treated with blue and white coloured glazes. The remarkable faience reliefs of animals which were discovered at Knossos, show a degree of sculptural beauty, design and life-like movement only surpassed by the best of the achievements in Greece.

China arrived at a point of some proficiency in the art during the Han dynasty, or a little before, and many of the tomb figures which were buried with the dead, though, in a sense, crude, are full of life and vigour. Immediately following this period, during the times of unrest between A.D. 26 and A.D. 618, the commencement of the T'ang dynasty, beautiful figures of men and animals were executed in a gray clay and painted with various colours, indications of which are evident on the specimens found to-day. Many of these statuettes were inspired by the Bactrian camels and the great horses which the Mongols introduced from the North into China. Imaginative forms were also created, prominent among which were three-horned, rhinoceros-like animals and dogs, sometimes of a ferocious nature.

With the dawn of the T'ang dynasty, which was a great period of refinement, China arrived at a point in this art parallel to that of the Greek achievements, and glazed and unglazed figures of great beauty were created. These were mortuary figures placed in the graves as symbols representing the living people whom it was the custom to entomb in earlier periods. The strength of the modelling of these figures surpasses that of the Tanagra figures but there is something lacking in the delicacy and charm which the Greeks succeeded in obtaining. (*See* POTTERIES AND PORCELAINS: *Near and Far East;* AEGEAN CIVILIZATION.)

(W. E. Cx.)

GREEK, ETRUSCAN AND ROMAN

Greek.—The uses of clay among the Greeks were varied and extensive. The pottery of terra-cotta vases are described in POTTERIES AND PORCELAINS.

Use in Architecture.—In architecture terra-cotta was extensively employed for roof tiles and other decorative details, as has been shown by discoveries made during research throughout Greece and the southern part of Italy, as well as in Asia Minor. In the Heraion at Olympia we have one of the oldest examples of a terra-cotta roof. A 7th-century temple at Thermon in Acarnania was constructed of wood and terra-cotta, with painted terra-cotta slabs in wooden frames for metopes. The generic term for a roof tile was *κέραμος*, and these are classified as flat square tiles (*στεγαστῆρες* or *σωλῆνες*) and semi-cylindrical covering tiles (*καλυπτῆρες*). Other varieties of ornamental tiles used in buildings are (1) the covering slabs along the raking-cornice (*γεῖσον*) of the pediment; (2) the *κυμάτιον* or cornice above the *γεῖσον*; (3) the cornice along the sides with lions' head spouts to carry off rain water; (4) the *ἀκρωτήρια* or antefixal ornaments surmounting the side-tiles. They were usually enriched with decoration in colour, the *κυμάτιον* being painted with elaborate patterns of lotos-and-honeysuckle or maeander, in red, blue, brown and yellow. The antefixes were usually modelled in the form of palmettes, but were sometimes adorned with reliefs of heads or figures, for instance in the temples at Olympia, Thermon, Kalydon, Capua and Tarentum. Many coloured roof tiles have been found at Olympia.

Use in Sculpture.—Terra-cotta is rare in Greece for large statues. In Italy, and also in Cyprus it was a favourite material. The difference is easily explained by the source of supplies, Greece having abundant provision of marble, Italy hardly any, at least until the opening of the Carrara quarries. From the Minoan period we have interesting examples of glazed and painted terra-cotta statuettes from Knossos and Petsofa (*see* Plate II., fig. 3) in surprisingly modern-looking costumes. Mycenaean examples are of a more schematic character.

Classical Greek traditions on the subject go back to one Butades of Sikyon, a potter who was credited with the invention of modelling clay in relief, and the Samian sculptors, Theodorus and Rhoikos, who lived about the end of the 7th century B.C. The small terra-cotta figures used as ornaments or household gods, buried in tombs or dedicated in temples have been found in large numbers on nearly all the well-known sites of antiquity, the most fruitful being Tanagra in Boeotia; Myrina and Smyrna in Asia Minor; Rhodes, the Cyrenaica, Athens, Sicily and some of the towns of southern Italy. They are also found in Cyprus and Sardinia, where, as to some extent in Rhodes, they follow a peculiar development, under the domination of Eastern influence. Many of the earlier types have a markedly oriental character. But in the Greek terra-cottas we may trace a steady development from the primitive types which correspond to the *ξόανα* of primitive Greek religion, and for the most part represent actual deities, down to the purely *genre* figures of Tanagra and other Hellenistic products. For beauty and charm the palm has by general consent been given to the Tanagra figures of the 4th and 3rd centuries B.C. so called after the little Boeotian town of Tanagra where

such statuettes were first found in tombs about 1870. They were known in antiquity as κόραι or "Maidens," from the presence of seated or standing types of girls in various attitudes; and the makers of these figures were known as κοροπλάσται.

Manufacture.—The Greek terra-cotta statuettes, though occasionally modelled and solid, are usually moulded and hollow. The process of manufacture was briefly as follows: A mould of clay was first made and baked to considerable hardness (Plate II., fig. 13). Its surface was then covered with layers of well levigated, moist clay until the required thickness was reached. The shrinkage of the clay in drying allowed the figure to be easily removed from the mould. The back was made separately (either in another mould or, if summarily worked, by hand) with a vent-hole for evaporation. To insure the desired diversity the head and arms were often moulded separately and different moulds variously combined The many hundred Tanagra statuettes in spite of their obvious similarity include few duplicates

The painting of the baked statuettes was practically universal. They were first covered entirely with an *engobe* of white clay and over this the colours were added. The garments show a variety of bright shades—blue, red, pink, yellow, brown, violet and, rarely, green. The colour of the flesh where preserved is generally reddish or pinkish, of the hair auburn brown, of the lips red, of the eyes blue. Gilt and black appear for details. Unfortunately the white coating has largely flaked off and with it the colours, leaving only the drab terra-cotta surface.

The purposes for which these statuettes were used, (*a*) for religious rites, (*b*) in daily life, (*c*) in funeral ceremonies, have been the subject of much debate. Since the same types and subjects are common to each of these classes of discoveries it is obvious that the terra-cottas cannot have been intended for one purpose alone, but served all three.

Subjects and Types.—The earliest statuettes show a limited range of subjects. As in other materials, so also in clay, the female deity reigns supreme. The primitive Hellenic type of goddess adopts two chief forms, the board-form σάνις and the column form κίων or ξόανον; both of these forms are found also in the sculpture of that time. The limbs are wanting, or are at best rudimentary. Another primitive type from Cyprus is shown in (Plate II., fig 1). Compared with these the Minoan ladies of a later period show a marked development. After this comes the retrogression observable in other products of the geometric epoch, out of which classical Greek art gradually emerges.

In Archaic Greek Art of the Sixth Century B.C.—The standing and seated goddesses (Plate II., fig. 4), in spite of their small dimensions often have a fine dignity and monumental character. A certain proportion of these deities are differentiated as nature-goddesses, either as a nude goddess in a shrine or a seated figure with a child in her lap who may be described as the Earth-Mother. Both types are of oriental origin. Another common archaic type is the funeral mask or bust, hollow at the back, which is found both in central Greece and Rhodes. Other characteristic products are little figures of animals, groups of men, women, and children, variously occupied, often of delightful spontaneity; and jointed dolls which can only have served the purpose of children's toys.

Terra-cotta statuettes are not nearly so common during the 5th century as in earlier or later times; the types continue those prevalent during the preceding epoch, but with an added serenity. The most flourishing period of production was from the later 4th to the 1st century, B.C., the period of the Tanagra and Myrina statuettes. These represent no longer divinities, but the people of their time as we might have seen them any day, only transformed into works of art by their makers' sense of beauty. Among the Tanagra statuettes, the most successful are the figures of the women and girls (Plate II., fig. 7). We see them standing in restful poses, sometimes leaning against a pillar, occasionally walking or sitting, but mostly quiet, serene and a little pensive. Only rarely are they portrayed in a definite action, such as doing their hair, carrying a child, or playing games. The youths are less successful, being somewhat conventional. Actors are occasionally found, wearing the customary insignia (Plate II., fig. 11), as well as such subjects as old nurses with infants (Plate II., fig. 12), and caricatures. In the Hellenistic period the centre of manufacture shifted from Tanagra to regions outside Greece proper. The little town of Myrina in Asia Minor, for instance, has been rendered famous by the extensive discoveries made there in 1880–1882. A comparison between these later statuettes and the Tanagra examples will show the differences which the Hellenistic spirit produced. Instead of the quiet, gentle women, youths and children of the preceding epoch, we have mostly figures in lively attitudes and often of mythological character; and even in the quieter types a new striving for effect is generally noticeable. Caricatures are now favourite subjects. Occasionally the statuettes are signed by their makers, so that we know a few names of these old artists (*e.g.*, Diphilos).

Clever forgeries of such Greek statuettes have been produced in large numbers and have found their way into many private and even public collections. Among them are large mythological groups, and though many of the figures copy fairly closely the standing and sitting types of the Tanagra figures, even these can generally be recognized by a certain affectation and theatrical quality which stamp them as un-Greek (Plate II., fig. 10). Sometimes the modern pieces are made from moulds taken from ancient statuettes, in which case it is occasionally difficult to pronounce judgment; but even here a certain indefiniteness in contour and often the addition of inappropriate details betray the hand of the forger.

Besides Tanagra and Myrina many other sites have yielded extensive finds of terra-cottas From Sicily we possess a complete series, from archaic to later times, the earlier being best represented at Selinus, where a great variety of richly coloured figures have been found; there are also many fine heads of 5th century style, and figures of Aphrodite, Eros and other deities imitating the later types of Hellenistic art. At Naukratis in the Egyptian Delta the later terra-cottas are strongly influenced by Egyptian ideas, and figures like Bes and Horus are found in conjunction with orientalized Aphrodite types. The terra-cottas of Tarentum stand apart from those of other sites, being markedly funereal in character; many represent Dionysos reclining at a banquet. Elsewhere in southern Italy the types correspond to those of Sicily and other Mediterranean sites.

Among terra-cotta work in relief, apart from definitely architectural examples, two groups, known respectively as "Melian" and "Locrian" stand out in importance. They both belong to the early 5th century and consist of small plaques The subjects of the Locrian reliefs, which mostly relate to the myth and cult of Persephone, seem to indicate that they at least were of a votive character. They occur at Locri in southern Italy, and similar examples dedicated to Athena have been found on the Acropolis at Athens. The Melian reliefs exhibit a wider scope of subjects, mainly mythological; the work is exceedingly delicate and refined in character. Some are simple plaques; others have the figures cut out without background, or sometimes with only the outer contours. These reliefs have been found on various Greek sites, some in Melos.

There is a class of vases which comes rather under the heading of terra-cotta than of pottery, from its technical character and general appearance. These are found at Canosa, Calvi, Cumae and elsewhere in southern Italy, and belong to the Hellenistic period. This terra-cotta work combines in a marked degree the characteristics of the vase and the statuette, some being vases with moulded reliefs or small figures in the round attached; others actual figures of colossal heads modelled in vase form, with the addition of mouth, handle and base. They are often of gigantic size, and do not appear to have served any practical purpose; probably they were made specially for the tomb. They are covered with a white slip like the statuettes, and are often richly coloured.

Etruscan Terra-cotta Work.—The people of Etruria employed this material both for finer works of art and for more utilitarian purposes. Pliny attributes its introduction to Corinthian refugees in the 7th century, and states that the art of modelling in clay was brought to perfection in Italy, and

ITALIAN AND FRENCH EXAMPLES OF TERRA COTTA SCULPTURE

1. "Nativity Group," glazed terra cotta figurines by Antonio Rossellino (1427–79), Italian
2. "Madonna and Child," statuette in glazed terra cotta by Donatello (1386–1466), Italian
3. "Bacchus and Nymph with Cupid," terra cotta statuette by Claude Michel (Clodion) (1738–1814), French
4. "Peasant Woman," terra cotta bust by Jules Dalou (1838–1902), French

especially in Etruria. The Romans employed Etruscan artists to decorate their temples, and the statue of Jupiter on the Capitol was made by Volca of Veii about 500 B.C., in clay painted vermilion, as was also the chariot on the pediment of the temple. Several painted clay statues of the end of the 6th century, have been found at Veii and are now in the Museo Papa Giulio. The statue of Apollo is the finest example we possess of Etruscan sculpture. For the decoration of temples terra-cotta remained in use even down to Roman times. Remains of temples with terra-cotta decoration have been found at Cervetri (Caere), at Alatri, and at Civita Castellana (Falerii), as well as at Civita Lavinia. Other remains of terra-cotta decorations come from Conca (Satricum), Orvieto, Pitigliano and Luni, where the pediment of the temple has the figures of Olympian deities, muses and the slaughter of Niobids, all executed in terra-cotta on a large scale. The date of these sculptures is about 200 B.C. At Alatri and Falerii the decoration consists of a complete system of terra-cotta plating over the woodwork of the roofs and architraves, ornamented with patterns in relief or painted and surmounted with carved antefixal ornaments.

The form of monument which best exhibits the Etruscan fondness for terra-cotta as a material for sculpture is the sarcophagus, of which some remarkable archaic examples exist, and a considerable number of later date. Among the former the most conspicuous example is the well-known Castellani sarcophagus in the British Museum, dating from the end of the 6th century B.C. The sides are decorated with friezes of figures in relief, and on the cover is a group of a man and a woman reclining, executed in the round life-size. There are similar examples in the Louvre, and in Museo di Papa Giulio at Rome, the British Museum (Plate III., fig. 5) and the Archaeological Museum in Florence. A large number of Etruscan terra-cotta urns for holding the ashes of the dead have been found on various sites. They date from the 3rd and 2nd centuries B.C. and in form are miniature sarcophagi with a figure reclining on the lid and reliefs on the front and sides (Plate III., fig. 6). The reliefs are often of a funerary character, representing the last farewell to the dead in the presence of Charon and other death-deities; others have mythological subjects, such as the combat of Eteokles and Polyneikes; the slaying of the dragon by Kadmos; or the parting of Admetos and Alkestis.

Roman Terra-cotta Work.—The uses of clay among the Romans were much the same as among the Greeks and Etruscans; the main differences were that in some cases its use was more extensive in Rome, in others less; and generally that the products of Roman workshops are inferior to those of earlier times. The Romans divided the manufacture of objects in clay into two classes: *opus figulinum* for fine ware made from *argilla* or *creta figularis* and *opus doliare* for tiles and common earthenware.

Ornamental tiles followed much on the lines of those used in Greece, though the latter are both simpler and inferior in design. Terra-cotta was largely used at Pompeii for this purpose. A characteristic feature of Pompeian houses is the trough-like gutter which formed an ornamental cornice to the *compluvium* or open skylight of the *atrium* and peristyle; these were adorned with spouts in the form of masks or animals heads, through which the rain-water fell from the gutters into the *impluvium*. Some good examples of roof-tiles and antefixal ornaments have also been found at Ostia.

Terra-cotta mural decoration was also largely employed by the Romans for both the interior and the exterior of their buildings. These were in the form of slabs ornamented with reliefs hung on the walls or round the cornices. Cicero speaks of fixing the bas-reliefs (*typos*) "on the cornice of his little atrium." These slabs usually measure about 18 by 9 to 12 in., and have nearly all been found in Rome, though isolated examples occur in other places. The reliefs were pressed in moulds, and the same subjects recur with slight variations due to retouching before the firing. A few modelled reliefs also exist. Circular holes are left in the slabs for the plugs by which they were attached to the walls.

Roman Sculpture in Terra-cotta.—Frequent allusions in classical writers indicate that the ancient statues of the Romans were mostly of terra-cotta, and Pliny notes that even in his day statuettes of clay were still preferred for temples. There are also references to *signa fictilia* placed on pediments of buildings such as the Capitoline temple. In 493 B.C. Gorgasus and Damophilus of Himera in Sicily ornamented with terra-cotta reliefs and figures of the temple of Ceres (now Santa Maria in Cosmedin). Towards the end of the republic modellers in clay are mentioned, such as Possis, who imitated grapes and other fruit, and the sculptor Arcesilaus. But their work in this material appears to have been confined to models for sculpture or metal work, and the invasion of the masterpieces of Greek art and the general adoption of marble by sculptors led to the neglect of terra-cotta as a medium of the glyptic arts. Few statues of any size in this material now exist. Some terra-cotta figures of considerable size were found at Pompeii, having formed the cult-statues of a temple; others were employed for adorning gardens, like a series from Rome in the British Museum. Terra-cotta figures were also employed as architectural members of the caryatid type. All these belong to the Augustan and succeeding period, or at least are not later than the reign of Nero.

This industry also extended from Rome to the provinces, and terra-cotta statuettes of local make have been found in Britain, as at Richborough, Colchester and London. In Gaul in particular, and in the Rhine district, there were very extensive manufactures of terra-cottas after the conquest of Julius Caesar in 58 B.C. They were made by local craftsmen for the Roman colonists, who introduced their own types of design. The principal centre of manufacture was the district of the Allier in central France. Potteries have been found at Moulins, as well as in other parts of France, in Belgium and Alsace, and along the Rhine.

Collections.—The best collections of Greek terra-cottas are in the British Museum, the Louvre and the museums of Berlin, Athens, Boston and New York. Etruscan terra-cottas are best represented in the museums of Florence and Perugia, and the Museo di Papa Giulio in Rome. The Roman examples are chiefly to be found in Rome and Naples as well as in provincial museums at Nîmes, Arles, in England and Germany.

RENAISSANCE PERIOD

After the downfall of the Roman empire in the west, the artistic use of terra-cotta was abandoned for many centuries, though, here and there, both in Italy and in the districts that had been once Roman provinces, decorated terra-cotta work was carried on sporadically both in parts of France and of Germany. The true renaissance of its use came during the 14th and 15th centuries, when it was adapted once more to architectural service in the Gothic buildings of northern Italy and of Germany. In Germany the mark of Brandenburg is especially rich in buildings enriched with modelled terra-cotta. The church of St. Catherine in the town of Brandenburg is decorated in the most lavish way with delicate tracery and elaborate string-courses and cornices enriched with foliage all modelled in clay; the town-hall of Brandenburg is another instance of the same use of terra-cotta. In northern Italy this use of terra-cotta was carried to an equally high pitch of perfection. The western façade of the cathedral

of Crema, the communal buildings of Piacenza, and S Maria delle Grazie in Milan are all striking examples of the extreme splendour of effect that can be obtained by terra-cotta work. Pavia itself is very rich in terra-cotta decoration.

With the revival of terra-cotta as an adjunct to mediaeval architecture we find the sculptors of the Italian renaissance turning to this material, as a medium for the production of reliefs, busts and even groups of many life-sized figures—again following the practice of classic times. Much of the Florentine terra-cotta sculpture of the 15th century is among the most beautiful plastic work the world has ever seen, especially that by Jacopo della Quercia, Donatello and the sculptors of the next generation. In the 16th century a more realistic style was heightened by painting the figures in oil colours. Many very clever groups of this kind were produced by Ambrogio Foppa (Caradosso) for S. Satiro at Milan and by Guido Mazzoni and Begarelli (1479–1565) for churches in Modena. The introduction of enamelled reliefs in terra-cotta which is so closely associated with the Florentine sculptor Luca della Robbia and his descendants, is specially treated in the article DELLA ROBBIA (*q.v.*).

From these two centres the development of architectural terra-cotta gradually spread over western Europe. The German school influenced the work done in the Low Countries and finally in England, where it also met the direct influence of the Italian school due to the invasion of England by Italian artists such as Torrigiano and others who were invited to England during the reigns of Henry VII. and Henry VIII.

France.—Another offshoot from the fertile plains of northern Italy was implanted in France during the 16th century. Many sculptors from northern and central Italy were attracted to France by Francis I. and his successors, and, among other arts, they introduced the making of artistic terra-cottas. The most famous name in the lists of these Italian artists is that of Girolamo della Robbia (*see* article DELLA ROBBIA), who executed, in 1529, the enamelled terra-cotta for the decoration of the "Petit Château de Madrid" in the Bois de Boulogne, Paris, for Francis I.

Spain.—At about the same period the Italian modellers or sculptors carried the art into Spain, and many extraordinary works are still extant in various Spanish churches remarkable for their vivid realism and for a too pictorial style which degrades them from their true rank as architectural decoration

During the 17th and 18th centuries the architectural use of terra-cotta again fell away owing to the increasing use of marble, but that the art still survived in other forms is shown by the portrait busts of Dwight (17th century), though they were made in stoneware and not in unglazed terra-cotta; and the charming little statuettes and groups made in Lorraine and the adjacent parts of France by Guibal, Cyfflé and Lemire, sculptors employed at some of the pottery factories of the period

It should be mentioned that during the 18th century ordinary clay had fallen into disrepute, but the porcelain figures made at Meissen, Sèvres and other continental factories show how persistent the vogue of figure-modelling in clay had become (*See* POTTERIES AND PORCELAINS.)

18TH AND 19TH CENTURIES

The last great revival of terra-cotta took place in the Sèvres plant and consisted of the "biscuit" figures and groups modelled with great skill by the best French sculptors of the day. Men like Pajou Pigalle, Clodion (Claude Michele), La Rue, Caffieri, Falconet, Boizot, Julien, Le Riche, etc., executed things of real artistic merit, for though lacking somewhat in the sculpturesque quality of stone-carving they were of great delicacy and life and obtained a sensual quality typical of the art of the day. This factory, however, from 1792 to 1801, as a result of the French Revolution, barely existed and was only revived later by Napoleon after which time, however, very little terra-cotta was executed.

Sculptors of the 19th and 20th centuries have been less inclined to this art for the reason that it involves a personal retouching of the detail of each piece, while the casting in bronze can be executed by skilled artisans. The unfortunate result is that few works are being done and those only from time to time in an experimental mood by various sculptors. (*See* SCULPTURE TECHNIQUE: *Terra-Cotta.*) (W. E. Cx.)

TERRAMARA, the term used of a Bronze age culture in northern Italy which was brought in by invaders who cremated their dead, in contrast to the practice of inhumation employed by the earlier Neolithic inhabitants. "The bodies were burned on a funeral pyre, and the ashes, together with the remains of offerings made at the burial, were placed in a large urn of pottery. Rows of these urns were then laid side by side in a separate area, which formed a village of the dead. . . Such was the custom of the people of the Terra Mare who occupied the whole valley of the Po on either side, but, except for one or two quite isolated colonies, did not penetrate into central or southern Italy." (D. Randall-MacIver, *The Iron Age in Italy*, 1927.)

See work cited and T. E. Peet, *The Stone and Bronze Ages in Italy and Sicily* (1909); also D. R. MacIver, *Villanovans and Early Etruscans* (1924).

TERRANOVA DI SICILIA: *see* GELA

TERRANOVA PAUSANIA, a seaport of Sardinia, in the province of Sassari, situated on the east coast, 72 m E. of Sassari by rail, and in the innermost recess of the sheltered gulf of Terranova. Pop. (1921) 5,071 (town); 6,593 (commune). It occupies the site of the ancient Olbia, and is the port of embarkation for Italy as in ancient times, the steamers plying nightly to and from Civitavecchia. There is some trade in cork and charcoal. The place is low-lying and malarious. The only building of interest is the Romanesque church of S. Simplicio, which dates from the 11th century. Pausania is a corruption of Fausiana, a town and episcopal see of Sardinia mentioned by Gregory the Great, the site of which is in reality uncertain.

TERRAPIN, the name given to certain fresh-water aquatic reptiles of the order Chelonia. (*See* TORTOISE.)

TERRE HAUTE (tĕr'ę hōt), a city of western Indiana, U.S.A., on the Wabash river, 73 m. W.S.W. of Indianapolis; county seat of Vigo county. It is on Federal highways 40 and 41; has a municipal airport; and is served by the Big Four, the Chicago and Eastern Illinois, the Chicago, Milwaukee, St Paul and Pacific, and the Pennsylvania railways. Pop (1920) 66,083 (89% native white); estimated locally at 80,000 (including suburbs) in 1928. The city occupies 10 sq m, 60 ft. above the river. It has 16 parks, covering 538 ac.; municipal swimming pools and golf courses; a stadium seating 16,000; 36 public and 8 parochial schools; 68 churches; and 3 daily newspapers. It is the seat of the Indiana State Normal School (established 1865 and opened 1870) and the Rose Polytechnic Institute, founded by Chauncey Rose (1794–1877) and opened in 1883; and 4 m N.W. is the college (for girls) of St Mary-of-the-Woods, founded in 1840 by the Sisters of Providence. Oil in commercial quantities has been found in Vigo county and in Sullivan (adjoining), and Terre Haute has a well which has been yielding for 40 years. Terre Haute is in the heart of a bituminous coal field and the output of the county was 4,468,773 tons in 1926. The city has a by-product coke plant with a capacity of 750 tons daily. Other important industries are railway shops, stamping works, paper and box factories, rolling mills, glass works and flour mills. The total factory output in 1925 was valued at $22,846,355

Terre Haute is one of the oldest cities of Indiana Fort Harrison (abandoned 1817) was erected here in 1810–11. In 1812 the fort was successfully defended against an attack of the Indians by its commandant Captain Zachary Taylor. Round the fort grew up a settlement, which developed after the War of 1812 into an important commercial centre The town was incorporated in 1838 and became a city in 1853 In 1860 it had a population of 8,594, which increased to 26,042 in 1880 and 36,673 in 1900.

TERRELL, a city of Kaufman county, Texas, U.S.A., 32 m. E of Dallas, on Federal highway 80, and served by the Texas and Pacific and the Southern Pacific railways. Pop. (1920) 8,349 (26% negroes). It is the seat of Texas Military College. There are cotton gins and compresses handling 35,000 bales in a season. Terrell was founded in 1873, when the first railway reached this point, and was chartered as a city in 1874. Since 1914 it has had a commission-manager form of government.

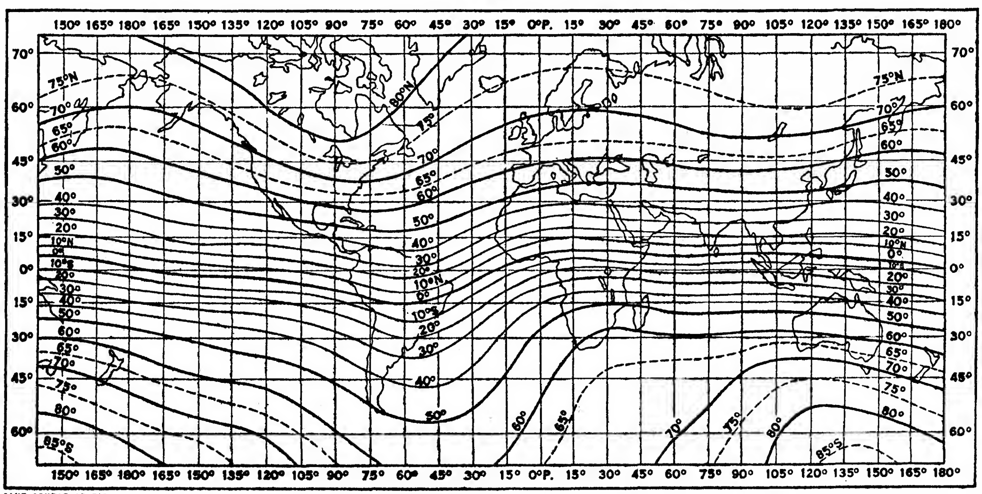
FIG. 1.—LINES OF EQUAL DECLINATION FOR 1922

TERRESTRIAL MAGNETISM, the science pertaining to the study of the magnetic phenomena of the earth.

It is probable that the directive property of loadstone was discovered independently in Europe and in China, but at a much earlier date in the latter than in the former. It is unlikely that the characteristic was known in Europe before the tenth century, but the Chinese were aware of it before the Christian era. Some go so far as to say that it was known in China as early as 2634 B.C., and there is evidence of the use, as early as 1110 B.C., of "south-pointing carts," *i.e.*, carts carrying a pivoted dummy with outstretched arm, and containing a magnet which caused the arm to point south. It has been claimed that, as early as the end of the eleventh century, the Chinese were aware of the fact that the compass needle does not point to the true north, but, as far as western civilization is concerned, Columbus is usually, although not universally[1] (Note: the superior figures in the text refer to the latter part of the bibliography at the end of this article) credited with the discovery during his voyage to America in 1492.

The discovery of the "magnetic dip" is usually attributed to Robert Norman, an English instrument maker who describes it in *The Newe Attractive,* published in 1581, and who constructed a form of dip circle and found a rough value for the dip in London. The secular change in the orientation of the compass needle was discovered and recorded in 1635 by Henry Gellibrand as a result of the measurements which had been made at Limehouse by William Borough in 1581, by Edmund Gunter in 1622, and by himself in 1633. (*See* COMPASS.)

The fact that the orientation of the compass varied throughout the day was discovered by George Graham in 1722, and a more careful analysis of the phenomenon was made from 1756–



SAME SOURCE AS FIG. 1

FIG. 2.—LINES OF EQUAL INCLINATION FOR 1922

1759 by J. Canton. About this time also a connection between magnetic disturbances and aurora was noticed by Canton and Peter Vilhelm Wargentin

Not until the end of the eighteenth century was it known that the earth's total magnetic intensity varied over its surface. The first to observe the phenomenon was a Frenchman, Paul de Lamanon, but the first published results are those of the traveller Humboldt who made observations between 1798 and 1803, using measurements of the time of oscillation of a dipping needle as a means of comparison of the total intensities at different places. The diurnal variation in the dip and in the horizontal intensity of the earth's magnetism was discovered by Arago in 1827.

The foundations of absolute methods for measuring terrestrial magnetic quantities were laid by Gauss, who initiated regular observatory work in terrestrial magnetism at Göttingen in 1834. Magnetic observatories were established at St Helena, Cape of Good Hope, Hobart, and Toronto by the middle of the 19th century, and since that time numerous observatories have sprung up in all parts of the world

General Considerations.—The magnetic field of the earth is roughly that of a uniformly magnetized sphere, and the field of such a sphere at external points is the equivalent of that due to a magnetic doublet placed at its centre According to an analysis of L. A. Bauer[2)] the values M of the resultant moment, M_p of the axial component and M_e of the equatorial component for this doublet are as follows:

$M=8{\cdot}04\times10^{25}$ c g s.; $M_p=7{\cdot}88\times10^{25}$ c.g.s.; $M_e=1{\cdot}60\times10^{25}$ c g s. The axis of the doublet intercepts the northern hemisphere in latitude 78° 32′ N and longitude 69° 08′ W The average intensity of magnetization, or moment per cubic centimetre of the earth is 0·074 c g s unit

The magnetic poles of the earth are defined as the places where the magnetic lines of force are vertical. Only very roughly may they be regarded as situated at the intersection of the prolongation of the axis of the doublet with the earth's surface From observations taken between 1903 and 1906, R. Amundsen placed the north magnetic pole at 71° N. latitude and 96° W. longitude The probable position of the south magnetic pole as calculated from data obtained on the "Discovery," 1902–4 is 72° 50′ S. latitude, and 156° 20′ E longitude

From a harmonic analysis of the earth's magnetic field, Gauss concluded that part was of external and part of internal origin. Analyses by A D Schmidt[3)], and later by L. A Bauer[2)] lead the authors to the conclusion that part of the field was of a form which could not be attributed to any distribution of magnetization inside or outside of the earth. In the technical mode of expression this part is one which is not derivable from a potential, and is of a type requiring for its explanation in terms of classical electrodynamics the existence of electric currents flowing through the atmosphere in the regions where the magnetic observations are made. Bauer concludes that about 94 per cent of the earth's magnetic intensity is attributable to a potential arising from internal sources, about 3 per cent to a potential arising from external sources, and about 3 per cent is of non-potential origin.

The values of the average vertical current densities necessary to produce the non-potential part are given in Table I for various ranges of latitude, according to Bauer's calculations[4)] derived from the magnetic data available in 1920.

The average value of the vertical current density taken regardless of sign is about 10,000 times the average atmospheric-electric current density (*see* ELECTRICITY: *Atmospheric*), so that if the former represents a reality the currents associated with it must be of a type produced, for example, by the influx or efflux of charged particles of high speed which derive their velocity from sources other than the atmospheric potential gradient.

According to the conclusions of Sir F. Dyson, and H. Furner[5], the non-potential part of the earth's magnetic field is not indicated with any certainty, although there is some evidence for it. Again, even as regards the part of the field depending upon a potential, different analyses have given different results depending on the data used. Thus the analyses made by Schmidt[6] on the basis of the data available in 1898 limits the surface field which can be of external origin to less than one per cent of the total; and the chief part of it is a uniform field of intensity 3×10^{-3} gauss.

The variable part of the earth's magnetic field corresponding to the diurnal variation has its main origin outside of the earth, and, according to S. Chapman[7], about 28 per cent of it owes its origin to sources inside the earth.

Gauss laid down the fundamental principle for the analysis of the earth's magnetic field corresponding to a case where the field was derivable from a potential.

It is well known that the potential Ω of any magnetic system can be expressed in polar co-ordinates, as a function of the distance r from the origin, the latitude l, and the east longitude λ in the form

$$\Omega=\sum_{n=0}^{n=\infty}\sum_{m=0}^{m=n}\left\{\frac{H_n^m(\sin l)}{r^{n+1}}(g_n^m\cos m\lambda+h_n^m\sin m\lambda)\right.$$
$$\left.+r^nH_n^m(\sin l)\,(g^m_{-n}\cos m\lambda+h^m_{-n}+\sin+m\lambda)\right\}\qquad(1)$$

where the g's and h's are constants known as Gaussian constants, and

$$H_n^m(\mu)=(1-\mu^2)^{\frac{1}{2}m}\left[\mu^{n-m}-\frac{(n-m)\,(n-m-1)}{2(2n-1)}\mu^{n-m-2}\right.$$
$$\left.+\frac{(n-m)\,(n-m-1)\,(n-m-2)\,(n-m-3)}{2\cdot4(2n-1)(2n-3)}\mu^{n-m-4}\;\ldots\right]$$

m and n being positive integers, with m not greater than n. Expressions for the components of the magnetic field may be obtained by differentiating the potential, and the various g's and h's may then be evaluated by determining them so as to cause the expression to fit the experimental data.

TABLE IV.

Secular Change in Total Intensity R, Declination D, and Inclination I, at Observatories

If we should work out the magnetic potential due to a distribution of doublets inside and outside of the sphere of radius r, we should obtain an expression of the type of (1), and the part of (1) involving the g_n^m and the h_n^m would depend entirely on the doublets outside the sphere of radius r, while the part involving g^{m}_{-n} and h^{m}_{-n} would depend entirely on the doublets inside that sphere. For this reason, in the empirical analyses of the earth's field, we regard the part depending upon the g_n^m and the h_n^m as due to external causes and the part depending upon g^{m}_{-n} and h^{m}_{-n} as due to internal causes.

The determination of the Gaussian constants from the experimental data is by no means as simple a matter as it might seem, and slight errors in the data are apt to cause large errors in the constants, particularly in those of high order.

Magnitudes of the Magnetic Elements over the Earth's Surface.—The elements which enter into the discussion of terrestrial magnetism data are:

The *Declination, D,* the angle made with the geographic meridian by the vertical plane containing a freely suspended compass needle.

The *Dip,* or *Inclination, I,* the angle made with the horizontal by a freely suspended compass needle

The *Horizontal Intensity, H,* the *Vertical Intensity V,* and the *Total Intensity, R* of the field

Between the four quantities I, H, V and R there exist the relations

$$\frac{H}{V}=\tan I,\quad R^2=H^2+V^2$$

so that a determination of any two of them serves to yield the others

Table II. gives, according to a compilation made in 1924[8], a list of values of the magnetic elements as recorded at various observatories throughout the world

It is customary to represent the characteristics of the earth's magnetic field by means of charts, in which on a map of the world are drawn the lines of equal Declination, or Isogonics, the lines of equal Inclination, or Isoclinics, and the lines of equal Horizontal Intensity, or Isodynamics, figs 1, 2 and 3, represent a set of such lines based on the British Admiralty Charts for 1922

Variations in the Earth's Magnetic Field.—The magnetic elements are in a state of change, and the variations may be divided into three main classes, those which follow a regular periodicity, those which follow an orderly change which is in one direction at any rate for long intervals of time, and those which are of a more abnormal nature and which, in their more drastic forms, at any rate, are classed under the head of magnetic storms.

The variations of a regular nature comprise a *Secular Variation,* and a periodic variation comprising a part, the *Diurnal Variation,* based upon a fundamental period of a day, and a part, the *Annual Variation,* based upon the fundamental period of a year. It is probable that the periodicities of all the members of the solar system reflect themselves upon the periodicity of the magnetic elements although, in general, to an immeasurably small degree, except in the case of the moon, where the effect is well marked. Data for the discussion of the Secular Variation in declination extend back to about 1540, but naturally with reliability decreasing with the remoteness of the epoch. For the Dip the data are fewer, and there are no absolute intensity measurements prior to 1830 The general orders of magnitude involved will be gathered from the facts that, at London, the Declination was 11° E. in 1580. It reached its extreme westerly value at 24° W. in 1810, and since then it has been changing towards the east until in 1925 it reached the value 13° W. A value of 71° 50′ was recorded for the Dip in London in 1576, a value of 74° 30′ in 1700, and the present value is about 67°.

From an analysis of the available data, L. A. Bauer has concluded that, over the period 1843–1923, the average intensity of magnetization of the earth has been decreasing at the rate of about one part in 1,500 per year. A digest of the available data for the declination is given in Table III, for the period 1540–1920[9], and Table IV.[9] illustrates the variation of intensity, declination and inclination over a period of 20 years (1905–25).

A method which has been used for illustrating secular change is as follows: Radii are drawn from the centre of a sphere parallel to the direction of the freely dipping needle, and are produced to intersect the tangent plane drawn at a point which answers to the mean position of the needle during the epoch under consideration. The curve formed by the points of intersection shows the character of the secular change. Figure 4[10] represents such a curve for London. The direction of description of the curve is clockwise, although this conclusion does not hold, apparently, for all places on the earth's surface. The inference suggested is that the curve will eventually close, indicating a periodic phenomenon with a period of about 480 years.

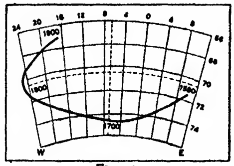

FIG. 3

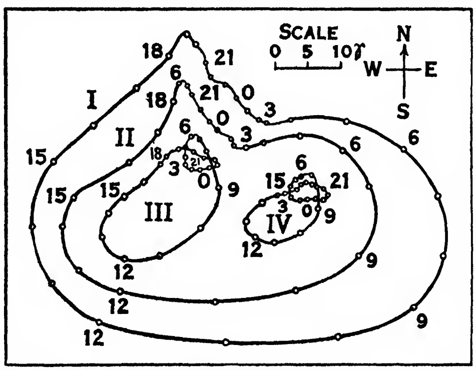
All the magnetic elements at any ordinary station show a regular variation throughout the day To separate this from the irregular changes, means of the hourly readings must be formed, making use of a number of days The amplitude of the diurnal change usually varies considerably with the season of the year, and to an extent depending upon the geographical location. The curves in fig. 5 constructed by D. L. Hazard[9] illustrate the general nature of the phenomena They are based on days selected because of their freedom from magnetic storms, and represent the average of a large number of days

A convenient method of exhibiting the diurnal variations of terrestrial magnetism is through the agency of vector diagrams, which give rather more complete information than is given by such diagrams as fig 4 In such a vector diagram, a vector representing in magnitude and direction the earth's total intensity is drawn from the point corresponding to the place of observation. The motion of the end of this vector then contains in three dimensions the story of the variations of all the elements In particular, the projection of this vector on a horizontal plane contains the story of the variation in the horizontal intensity.

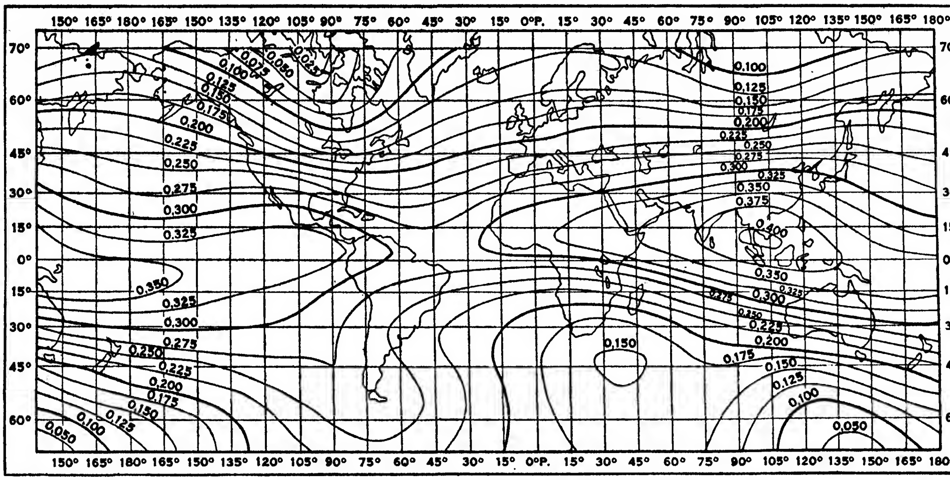


FROM GLAZEBROOK, "DICTIONARY OF APPLIED PHYSICS"

FIG. 4.—QUIET-DAY VECTOR DIAGRAMS OF THE DAILY VARIATION OF MAGNETIC FORCE IN THE HORIZONTAL PLANE AT GREENWICH, 1889–1914
I. June, sunspot maximum years; II. June, sunspot minimum years; III. December, sunspot maximum years; IV. December sunspot minimum years

By attaching to such a curve figures representing the time of day, the time variations of the element may be exhibited on the diagram. The sort of information representable in such a manner is indicated by the curves in fig. 4, which are drawn with particular reference to the influence of sunspot activity on the diurnal variation.

The more or less regular variations presented by the diurnal variation curves of fig. 4 are by no means characteristic of the individual days. On certain days the elements vary everywhere over the earth's surface, and to an extent large compared



SAME SOURCE AS FIG. 1

FIG. 5.—LINES OF EQUAL HORIZONTAL INTENSITY FOR 1922

with the normal diurnal variation. The larger disturbances of this type are known as magnetic storms. Days particularly free from such disturbances are termed quiet days. As a rule the conditions lie somewhere between the two extremes. The more important disturbances occur almost simultaneously all over the earth and for this reason it is possible to speak of the magnetic character of a day regardless of the location, the day being measured in terms of Greenwich time. It is customary for magnetic observatories to assign "Character figures" 0, 1, or 2 to each successive day, 0 denoting a quiet day, 2 a disturbed day, and 1 a day of intermediate type.

Terrestrial Magnetic Measurements. *Non-electrical Methods of Measurement.*—Of the magnetic elements D, I, H, V, R, only the declination D, and two of the others need be measured independently, the remaining elements may then be calculated. Measurements may be divided into two classes, those in which isolated values of certain elements are measured, and those in which continuous records of the variations of the elements are obtained. The latter class of measurements is confined almost exclusively to fixed observatories, and the elements whose variations are recorded are usually the declination, the horizontal intensity and the vertical intensity. (*See* MAGNETOGRAPH.) The former class comprises field observations on land and sea, and also observatory observations. The elements usually measured are declination D, horizontal intensity H, and dip (or inclination) I. The declination is obtained by measuring the angle made by the axis of a freely suspended magnet with the geographical meridian. Absolute measurements of the horizontal intensity are usually obtained by determining for a magnet of moment M, the product MH by one series of experiments and the ratio M/H by another. H^2 may then be evaluated by dividing MH by M/H. For the determination of MH the time of swing T of the magnet freely suspended in a suitable holder is determined. If K is the moment of inertia of the suspended system,

$$T = 2\pi\sqrt{\frac{K}{MH}} \qquad (2)$$

The moment of inertia is then increased to $K+k$ by the addition of a non-magnetic cylinder of known moment of inertia k. The time of swing T_1 is then determined.

$$T_1 = 2\pi\sqrt{\frac{K+k}{MH}} \qquad (3)$$

By the elimination of K between (2) and (3) we readily derive the expression

$$MH = \frac{4\pi^2 k}{T_1^2 - T^2}$$

for MH in terms of known quantities.

The ratio M/H is obtained by measuring the deflection θ from the magnetic meridian produced in a subsidiary suspended magnet when the magnet of moment M is placed with its axis horizontal, perpendicular to the deflected axis of the subsidiary magnet, and passing when prolonged through the axis of suspension. Under these conditions

$$H\sin\theta = \frac{2M}{r^3}\left(1 + \frac{P}{r^2} + \frac{Q}{r^4}\cdots\right)$$

where r is the distance from the centre of the magnet of moment M to the point of suspension of the other magnet, $\frac{2M}{r^3}$ represents the field due to the former magnet at the centre of the latter under the approximation that the said former magnet may be treated as a simple doublet of moment M, while P and Q are constants which provide for a correction on account of this assumption. It is customary to neglect Q. Then, by taking deflections at two different values of r, two expressions may be obtained from which P may be eliminated and M/H determined in terms of measured quantities.

In practice, a rather elaborate series of observations is gone through for the purpose of elimination of various errors in both D and H. (*See* MAGNETOMETER.) The classical method of determining the inclination is by the use of the dip circle, in which a magnetic needle is mounted so that it can turn in a vertical plane which is adjusted to lie in the magnetic meridian. In order to obtain an accurate result from the instrument many sources of error must be recognized and eliminated by a systematic series of observations. For the standard procedure *see* INCLINOMETER.

Electrical Methods.—Within recent years, the principle of comparing the earth's horizontal intensity with that produced by a measured current in a coil of known dimensions has been occasionally employed in observatories in one or other of various possible forms. In an instrument designed by F. E. Smith, following the suggestion of Sir Arthur Schuster, the principle is [11]:

A coil of the Helmholtz-Gaugain type, designed so as to secure a field constant to one part in 100,000 within a sphere of 30 mm. diameter, is used to produce the magnetic field to be compared with that of the earth. At the centre of this coil a small magnet is suspended, and the principle of the method involves balancing the earth's horizontal intensity with the field produced by the

coil, which field is given by Fi, where i is the current and F a constant calculable from the geometrical constants of the coil. One could secure the balance between Fi and H by adjusting i to secure an infinitely long period of vibration of the suspended magnet, but, a more practicable method, and the method followed, is one which invokes the fact that if the axis of the coil be set at an angle α to the magnetic meridian, it is possible to adjust i so that the magnet sets itself perpendicular to H in which case

$$Fi\cos\alpha = H.$$

The procedure, except for details is as follows. The axis of the coil is first set so that on starting or stopping the current, no deflection is obtained in the suspended magnet The axis is then in the magnetic meridian, and the direction of the field of the coil is the same as that of H, the horizontal component of the earth's field. The axis is now turned through a slight angle α. The current in the coil is reversed and adjusted so that the axis of the magnet becomes perpendicular to the magnetic meridian For convenience, the final adjustment of this condition is made by adjusting α rather than i. Next, keeping i constant, the axis of the coil is turned to approximately an equal angle β on the other side of the magnetic meridian, so that the magnet swings through 180°. The angle β is adjusted so that the angle through which the magnet swings is exactly 180° and the magnitude of the horizontal intensity is then given by

$$H = F.(\cos\alpha + \cos\beta)/2$$

The precision of the method is such as to permit of an accuracy of a few parts in 100,000 by measurements lasting only a few minutes, although in seeking this accuracy, attention must be given to many details not mentioned here[11)].

A method to some extent analogous to the foregoing was also devised by W. M Hicks[12)] and submitted to experimental test by W. A. Jenkins. Yet another absolute instrument for the purpose takes the form of a sine galvanometer designed by S. J. Barnett[13)].

For the determination of the dip, the dip circle has been superseded in many cases by the earth-inductor[14)], in which a coil is rotated about an axis in its own plane, the axis being adjusted until no current is obtained in the coil In this case the axis coincides with the direction of the earth's lines of force. The earth inductor must, of course, be provided with a commutator, and the galvanometer used must be situated sufficiently far from the apparatus to insure that its stray field shall not affect the measurements.

Field Terrestrial Magnetic Observations.—For land observation in the field it is customary to use the dip circle for inclination, and the magnetometer for declination and horizontal intensity determinations However, the usual procedure is to determine at a fixed observatory the moment of inertia of the suspended system, used in the oscillation experiments, and then employ this value throughout for the field observations.

In sea observations[15)], it is customary to use for declination a type of pivoted magnet system which is immersed in a liquid so as to remove much of the weight from the pivot and so reduce the friction. The geographical meridian is determined by observations on celestial bodies

For inclination both the earth inductor and a specially mounted dipping needle have been employed.

Total intensity observations have been made at sea by a method devised by E. Lloyd. The method involves two operations, during both of which the dip circle is placed so that the suspended needle swings in the plane of the magnetic meridian. In north magnetic latitudes, for example, the inclination is measured with a needle having a weight added to its south end. Then the needle is used to deflect a second dip needle when placed at right angles to its undeflected direction and at a definite distance. The first measurement serves to give a relation between R, the weight, and the moment M of the loaded magnet. The second measurement gives a relation between M and R, so that from the two relations M may be eliminated, leaving an expression for R in terms of the loading weight.

Measurements of the horizontal intensity are made by measuring the angle of deflection produced in the liquid compass by a magnet placed above it with its center on the vertical axis through the pivot, and with its length horizontal and perpendicular to the deflected direction of the axis of the pivoted needle. Under this condition

$$H = mc/\sin u$$

where u is the angle of deflection, m is the moment of the deflecting magnet, and c is a constant depending upon the position of the deflecting magnet, etc. The constant quantity mc is evaluated by making measurements with the instrument at a fixed observatory where H is simultaneously measured by the usual methods.

THEORIES OF TERRESTRIAL MAGNETISM

Theories Involving Permanent Magnetization.—While it is true that a complete theory of terrestrial magnetism must take account of the variations of the earth's magnetism with time, and of the non-coincidence of the geographic and magnetic axes we should feel that we had made a reasonably satisfactory advance if we could see some way in which to account for any sort of a magnetic field of the right order of magnitude even though our theory should require that field to be symmetrical with respect to the axis of rotation and to show in its simplest form no secular variation.

The first idea which suggests itself is that the earth's interior may be of magnetizable substance, and that somehow or other, at some time or other it became magnetized We cannot escape so easily the responsibilities of an explanation, however, for our ideas as to the temperature of the earth's interior place grave difficulties in the way of an assumption of a state of magnetization in the earth's interior; since, under ordinary conditions, iron, for example, would lose its capacity for magnetization at temperatures which would be reached at a depth of about 20 kilometers, and magnetite ceases to be magnetic at even lower temperatures than iron. Thus, unless we invoke some unknown effect of pressure to increase the temperature at which a substance loses its capacity for magnetization we must confine the possibilities as regards permanent magnetization to a relatively thin shell of the earth

A uniformly magnetized sphere of radius a, magnetized to an intensity I, acts at external points like a doublet of moment $M = \frac{4}{3}\pi a^3 I$, and a shell of thickness δa acts like the difference of two such spheres of radii a and $a - \delta a$. It acts in fact like a doublet of moment $\delta M = 4\pi a^2 I \delta a$. In order that δM should correspond to the effective moment of the earth it is necessary to assume a value of about 50 for I if δa is to be as small as 15 or 20 kilometers. While this value of the intensity is not large beyond all reason its existence seems highly improbable.

Theories Involving Rotation of Charge Distributions.—It is difficult to resist the temptation to believe that the earth's magnetism may arise as a result of its rotation As a guide in such considerations we have the experimental fact, as revealed by study of the Zeeman effect, that the sun possesses a magnetic field whose intensity at its pole is about 50 gauss. Further, the magnetic field which could arise from the rotation, at attainable speeds, of bodies of laboratory size must necessarily be small, as otherwise such magnetic fields would have revealed themselves long ago. Any theory which attempts to explain terrestrial magnetism as a result of rotation must lead to a formula consistent with the above facts.

The fact that a rotating charged body produces a magnetic field, leads one to inquire as to whether the earth's charge (*see* ELECTRICITY, ATMOSPHERIC) may, by its rotation with the earth, produce a magnetic field comparable with that of the earth. Calculation shows, however, that the field so produced would be a hundred million times too small. The magnetic potential Ω at a point with polar co-ordinates r and θ is given by

$$\Omega = \frac{Q\omega a^2}{3cr^2}\cos\theta$$

where Q is the total charge in electrostatic units, c the velocity of light, ω the angular velocity and a the radius of the sphere. The field outside the sphere is, in fact, similar to that of a doublet of

moment $Q\,\omega\,a^2/3c$. Its general form would be approximately correct as corresponding to the part of the field symmetrical about the axis of rotation, but only as viewed by an observer who did not participate in the rotation. Whenever we have to deal with a magnetic field produced by the rotation of a system which also has an electric field, we are faced with a difference between the magnetic field as it appears to an observer stationed on the rotating body and to an observer who does not participate in the motion[16)17)]. In the case of the rotation of a charged earth cited above, the effect would, for an observer on the earth, cause a reversal of the horizontal intensity as seen by a stationary observer, while leaving the vertical intensity unchanged. The effect of this is to produce over the surface of the sphere a distribution of field quite inconsistent with the facts.

The easiest way to demonstrate the effect of the observer's motion is through the theory of relativity. Thus if H is the magnetic field as viewed from one system of axes, the magnetic field H' as viewed in a system of axes moving relatively to the first system with velocity v parallel to the axis of x is such that

$$H_x'=H_x,\ H_y'=\beta\left(H_y+\frac{v}{c}E_z\right),\ H_z'=\beta\left(H_z-\frac{v}{c}E_y\right)$$

when $\beta=\left(1-\frac{v^2}{c^2}\right)^{-\frac{1}{2}}$ c is the velocity of light, and where E is the electric field as measured in the first set of axes.

Thus, if the axis of x be taken to coincide instantaneously with the direction of motion of a point on the sphere at the place of observation, and if the axis of z be taken to correspond to the vertical, and the axis of y to the meridian, then for a case where $E_y=0$, we have

$$H_x'=H_x,\ H_y'=\left(H_y+\frac{v}{c}E_z\right),\ H_z'=H_z$$

where, in putting $\beta=1$ we have neglected only quantities of the second order in v/c. Thus, the only effect of the observer's motion is on the horizontal component H_y'.

The quantity of positive and negative electricity in the earth is enormous. Thus if all the positive and negative electricity in a cubic centimetre of the earth's substance were separated and concentrated at two points a centimetre apart, they would attract each other with a force of 10^{20} tons.

If we could annul the positive charge and leave only the negative, the rotation of the earth would produce a field about 5×10^{18} times that of the earth. Since two spheres of equal charge but different radii produce unequal magnetic fields at a point external to both it occurred to Sutherland that only a slight difference would be necessary in the radii of two superposed spheres of positive and negative, of which the earth may be regarded as being composed in order that, by the combined rotation of these spheres, a field comparable with that of the earth would result. As a matter of fact calculation shows that the radii need only differ by $2{\cdot}4\times10^{-10}$ cm., *i.e.*, about one hundredth of the diameter of a single atom in order to produce the desired effect. Moreover, since a symmetrical spherical distribution of charge produces at external points an electric field which is independent of the size of the sphere, the two equal and opposite charges would together produce no electric field at an external point. However, as regards regions just inside the surface the condition is different. Thus, at a point just inside the thin shell of thickness 10^{-10} cm., there would be a field of the order 6×10^8 volts per centimetre tending to annul the separation which had taken place. This is demonstrated thus:

The magnetic potential Ω due to a sphere of radius a and uniformly distributed volume charge of total amount Q is, at an external point with co-ordinates r, Q, given by

$$\Omega=\frac{Q\omega a^2}{5cr^2}\cos\theta.$$

The potential $\delta\Omega$ due to two superposed spheres of equal charge, but of radii a and $a+\delta a$ respectively, is consequently

$$\delta\Omega=\frac{2}{5}\frac{Q\omega}{c}\frac{a\delta a}{r^2}\cos\theta.$$

The magnetic field H_z at the pole is

$$H_z=\frac{4}{5}\frac{Q\omega\delta a}{ca^2}.$$

At a point just inside the layer of thickness δa, the electric field due to the superposed spheres is

$$E=\frac{Q}{a^2}-\left(\frac{a}{a+\delta a}\right)^2\frac{Q}{a^2}=\frac{3\delta a}{a^3}Q.$$

Hence,

$$\frac{E}{H_z}=\frac{15}{4}\frac{c}{\omega a}$$

Inserting appropriate values for H_z, c, ω and a, we readily find $E=2\times10^6$ e.s.u., *i.e.*, 6×10^8 volts per cm.

A solid sphere of negative electricity would, by its rotation give a magnetic field roughly similar to that of the earth, as viewed by an observer who did not participate in the motion. As viewed by an observer on the sphere, however, the considerations referred to above cause a reversal of the apparent horizontal component while leaving the vertical component unchanged. The latter consideration may be avoided by coating the surface of the sphere with a uniform charge of sign opposite to but of total amount equal to that of the volume distribution, so as to annul the external field[17)]. The magnetic potentials due to the combined distribution is then

$$\Omega=\frac{Q\omega a^2}{5cr^2}\cos\theta-\frac{Q\omega a^2}{3cr^2}\cos\theta.$$

The first term on the right hand side corresponds to the volume charge and the second to the surface charge. The effect of the surface charge is thus to reverse the sign of Ω from that given by the volume charge. In other words, in order to produce a magnetic field corresponding to that of the earth we should have to postulate a positive volume charge, and a negative surface charge. Here again, however, the electrostatic pull on the negative surface charge as a result of the volume charge would be enormous, the field just inside the surface layer being of the order 10^8 volts per centimeter. There is consequently no obvious way in which the separation of charges could be maintained.

A modification of the foregoing possibilities is to be found in supposing that the rotation brings about a radial polarization in the atoms. The rotation of such a polarized system gives rise to a magnetic field, and also, of course, to an electric field. The latter may be compensated at external points by a suitable distribution of charge over the surface, and the rotation of the combined electrostatic distribution would produce a magnetic field[17)]. On submitting the matter to calculation, we find that the polarization necessary to give rise to a magnetic field comparable with that of the earth is such as would correspond to each having the moment which it would acquire by the separation of a proton and electron to the extent of an atomic diameter. (*See* ATOM.) While the distribution of charge over the surface would come about automatically in the case of conducting atmosphere, it would, however, not remain on the surface since the polarized distribution of the interior would give rise to an enormous field of the order of 10^6 volts per centimetre tending to draw it inwards. A possibility closely resembling the foregoing is one suggested by Sir Joseph Larmor[18)], who examines the consequences of supposing that the earth may be regarded as a rotating polarized crystal.

The complete inadequacy of non-electrical forces of ordinary type to maintain against the electrostatic forces such charge distributations as would be necessary to produce, by their rotation, a magnetic field comparable with that of the earth may be illustrated by one or two examples. Thus, the centrifugal force of the earth's rotation would, in a conducting earth cause a flow of electrons to the exterior until compensation was attained by the electrostatic forces. On submitting the matter to calculation[19)] we find that the magnetic field which results is only about 10^{-23} of the earth's field. Moreover, for an observer situated on the sphere, the horizontal component H would be of the same sign as that of the earth for latitudes 0° to 26·6°, and of opposite sign for other latitudes, while the vertical component would be of the same sign as that of

the earth for latitudes 0° to 51° and of opposite sign elsewhere.

The effect of centrifugal force is to produce (a) a uniform volume distribution giving rise at external points to a magnetic potential

$$\Omega_1 = 2m\omega^3 a^5 \cos\theta / 15c^2 er^2$$

where e and m are the electronic charge and mass. (b) A uniformly distributed surface charge of total amount equal and opposite to the volume charge, and giving rise to a magnetic potential

$$\Omega_2 = -2m\omega^3 a^5 \cos\theta / 9c^2 er^2$$

(c) A non-uniformly distributed surface charge of total amount zero, giving rise to a magnetic potential

$$\Omega_3 = \frac{-m\omega^3 a^3}{3c^2 e}\left\{\frac{a^2}{3r^2}\cos\theta - \frac{3a^4}{14r^4}(5\cos^3\theta - 3\cos\theta)\right\}.$$

The external electrostatic potential arises only from the non-uniformly distributed charge, and is given by

$$V = \frac{m\omega^2 a^5}{3er^3}(1 - \tfrac{3}{2}\sin^2\theta).$$

If the free electrons in the substance of the earth are affected by gravity, we should expect them to tend to congregate towards the centre until equilibrium was established on account of their pressure and electrostatic repulsion, the latter equilibrating influence being the all important one. On submitting the matter to calculation[19], we find that the magnetic field which results is of the order 10^{-21} of the earth's field, and is moreover opposite in sign to that of the earth

The solution for the foregoing case gives (a) a uniform negative volume charge of such amount as to give rise to a magnetic potential

$$\Omega_1 = -4\pi DGm\omega a^5 \cos\theta / 15c^2 er^2$$

D being the density of the earth's substance, and G the gravitational constant. (b) A uniformly distributed positive surface charge of total amount equal to that of the volume charge, and giving rise to a magnetic potential

$$\Omega_2 = 4\pi DGm\omega a^5 \cos\theta / 9c^2 er^2$$

There is of course no external electrostatic field.

Owing to the fact that the inside of the earth is hot, the pressure of the free electrons in the earth's interior will exceed that in the cooler parts, and there will be a flow of electrons until the remaining difference in pressure is balanced by the difference of potential set up The potential difference which arises in this manner is none other than that corresponding to the well-known Thomson effect. The rotation of the charge distribution set up by this process gives rise to a magnetic field. If we submit the matter to calculation[19] on the classical theory of electron equilibrium, we find that the results depend upon the type of the radial temperature and are greatest for the case where the gradient takes place entirely in a shell near the surface. In this case, assigning a total temperature change of 5,000° C, we find that the resulting magnetic field produced is of the order of 10^{-17} of the earth's field. The sign of the field corresponds to that of the earth.

The analysis for this case shows a volume distribution of positive charge and a surface distribution of negative charge Since both are symmetrically distributed (although the volume charge is not uniformly distributed) there is no external electric field.

If, in accordance with the customary assumption in electron theory of thermionic effects we assume the number n of free electrons per c.c. to be proportional to the 1·5 power of the absolute temperature T, we find for the magnetic potential due to the combined system of charges

$$\Omega = \frac{-16}{9}\frac{a\omega\cos\theta}{c^2 er^2}\int_{T_s}^{T_c} R^3 dT$$

when R is the distance from the centre of the sphere to a place where the temperature is T, and T_s and T_c are the temperatures of the surface and centre of the sphere respectively. For the case where the whole temperature drop occurs in a thin shell, near the surface the integral assumes the form $a^3(T_c - T_s)$.

The foregoing considerations will serve to emphasize the general principle that, at any rate, unless we are willing to alter our fundamental laws, it is impracticable to attempt any explanation of the earth's magnetism as a result of the rotation of charges which have been separated against electrostatic attraction, since the mechanical forces necessary to produce the required separation must be, in all cases, enormous and far beyond the limits of such forces as are available.

Possibilities of Modification of Laws.—Many years ago, Lorentz suggested a modification of the laws of electrical attraction and repulsion with the object of accounting for gravitation He assumed that unlike units of charge attracted each other with a force slightly greater than that with which like units repelled each other. It would result from this that two pieces of neutral matter would exhibit an attraction, and this attraction he associated with gravitation.

If, assuming that unit charges of either sign are defined so that the repulsive force between like charges, e_1, e_2 is $\frac{e_1 e_2}{r^2}$, we also assume that the force exerted by a positive charge e_+ on a negative charge e_- is $(1+\alpha)\frac{e_+ e_-}{r^2}$ and the force exerted by a negative charge e_- on a positive charge e_+ is $(1-\beta)\frac{e_- e_+}{r^2}$, where α and β are small positive quantities, we obtain a wider range of possibility[20].

It would, on this hypothesis, result that a free electron in a neutral sphere would not be in equilibrium since the attraction on it due to the positive charges within would outweigh the repulsion due to the negative It would be necessary for the sphere to acquire a negative charge in order that equilibrium should be established, and it is possible to determine α so that this negative charge would be such as to give rise by its rotation to a magnetic field comparable with that of the earth. While β plays no part in determining the equilibrium of a free electron, it does play a part in determining the total force which would be exerted on the element of matter composed as it is of both positive and negative electrons; and, it is possible to determine β so that the net force on the element of matter is just such as to correspond to gravitation. In order to account on these lines for both terrestrial magnetism and gravitation, it is necessary to have $1+\alpha = 1 + 1\cdot 9\times 10^{-19}$, and $1-\beta = 1 - (1\cdot 9\times 10^{-19}) + (0\cdot 78\times 10^{-36})$ so that both α and β are zero to within all limits of detection by laboratory experiments We obtain by our hypothesis a volume charge sufficient to give by its rotation the earth's magnetic field; but, our modification of the law of attraction has saved us from the consequences of a very large electric field such as we should encounter on classical lines; and, indeed, the residual electrical forces have been adjusted so as to no more than satisfy the demands of gravitation.

The details of the calculation are as follows: let ρ_+ and ρ_- be the densities of positive and negative electricity, respectively.

The condition that a free electron in the matter shall be in equilibrium is

$$\text{grad}\,(1+\alpha)\iiint\frac{\rho_+}{r}d\tau + \text{grad}\iiint\frac{\rho_-}{r}d\tau = 0 \qquad (4)$$

where the integrals are taken throughout the regions comprised by the matter.

The force on all the electricity in an element of volume dV is

$$\left[\text{grad}\,(1+\alpha)\iiint\frac{\rho_+}{r}d\tau + \text{grad}\iiint\frac{\rho_-}{r}d\tau\right]\rho_- dV$$
$$+\left[\text{grad}\,(1-\beta)\iiint\frac{\rho_-}{r}d\tau + \text{grad}\iiint\frac{\rho_+}{r}d\tau\right]\rho_+ dV \qquad (5)$$

where, in the general case, the ρ's might be functions of the coordinates. This is the quantity which the theory makes equal to the gravitational force on the element of volume dV. Thus, using (4) and (5), we have

$$\left[\text{grad}\,(1-\beta)\iiint\frac{\rho_-}{r}\,d\tau+\text{grad}\iiint\frac{\rho_+}{r}\,d\tau\right]\rho_+dV = \left[\text{grad}\,G\iiint\frac{D}{r}\,d\tau\right]DdV \quad (6)$$

where D is the density of the matter. Now, if m_+ and m_- are the masses of a proton and an electron, respectively, and N_+ and N_- the corresponding numbers of these entities per c.c.,

$$D=N_+m_++N_-m_-.$$

For a body which is sensibly neutral, or for which N_+-N_- is small compared with N_+, we consequently have

$$D=N_+(m_++m_-)=\frac{\rho_+}{e}(m_++m_-) \quad (7)$$

where e is the electronic charge, so that, from (6),

$$\text{grad}\,(1-\beta)\iiint\frac{\rho_-}{r}\,d\tau+\text{grad}\iiint\frac{\rho_+}{r}\,d\tau = \left(\frac{m_++m_-}{e}\right)G\,\text{grad}\iiint\frac{D}{r}\,d\tau. \quad (8)$$

For (4) and (8) to be true, it is sufficient that

$$(1+\alpha)\rho_++\rho_-=0 \quad (9)$$

and

$$(1-\beta)\rho_-+\rho_+=\left(\frac{m_++m_-}{e}\right)GD \quad (10)$$

and these conditions are also *necessary* if (4) and (8) are to be true for bodies of all shapes.

From (10) and (7),

$$(1-\beta)=-\frac{\rho_+}{\rho_-}\left[1-\left(\frac{m_++m_-}{e}\right)^2G\right]. \quad (11)$$

The net quantity of electricity ρ per unit of volume is,

$$\rho=\rho_++\rho_-. \quad (12)$$

Hence, from (11) and (12),

$$1-\beta=\left[\frac{1}{1-\frac{\rho}{\rho_+}}\right]\left[1-\left(\frac{m_++m_-}{e}\right)^2G\right] \quad (13)$$

i.e., approximately

$$\beta=-\frac{\rho}{\rho_+}+\left(\frac{m_++m_-}{e}\right)^2G \quad (14)$$

and from (9) and (12)

$$\alpha=-\frac{\rho}{\rho_+}. \quad (15)$$

Since ρ_+ is given in terms of D by (7), equations (14) and (15) serve to determine α and β in terms of $(m_++m_-)/e$, G and ρ. The last named quantity becomes determined as the value necessary to give rise to the earth's magnetic field as a result of its rotation. The necessary value of ρ is

$$\rho=-3{\cdot}0\times10^{-4}\text{e.s.u.}$$

Putting $G=6{\cdot}6\times10^{-8}$, $D=5{\cdot}5$, and $\frac{m_++m_-}{e}=0{\cdot}345\times10^{-14}$, we readily find

$$\alpha=1{\cdot}9\times10^{-19};\quad \beta=1{\cdot}9\times10^{-19}+0{\cdot}78\times10^{-36}.$$

Tempting as the foregoing view may seem, it is not without its difficulties. For, it turns out that if we desire to formulate a complete scheme of electrodynamics in such a manner as to conform to the requirements of the theory of relativity, we must not allow ourselves to modify the law of force between statical charges without modifying that between moving charges as well, and in the same ratio. Now the effect of motion of a charge on the force exerted on that charge by other charges is precisely the effect which we recognized as that of the magnetic field caused by those other charges; and, when everything is taken into account, it turns out that the magnetic field caused by the rotation of the positive electricity is different in magnitude as well as in sign from that caused by the rotation of an equal distribution of negative electricity, and the difference is just such as to cancel the magnetic field resulting from the excess of one kind of charge over the other[20]. Thus, the net result is that no magnetic field is obtained as a result of the rotation of the system; and, the only way in which to secure a magnetic field on these lines is to sacrifice conformity with the requirements of the restricted theory of relativity.

Possibilities in Circulation of Currents.—If currents flowed in circles with planes perpendicular to the earth's axis, they would generate at external points a field roughly similar to the earth's field. If the current density were uniform throughout the earth its magnitude would have to be of the order of 10^{-8} ampere in order to provide for the facts, and the general order of magnitude would not be materially altered if the current density varied throughout the earth in any manner which preserved the same order of magnitude for the greater part of the earth's volume. One's first thought concerns the question of where the electromotive forces necessary to maintain such currents could come from, and here we encounter a rather curious phenomenon. The electrical inertial considerations (self induction) in the case of a body of the earth's size become of enormous importance, so that currents once generated take a long time to die down after the source of electromotive force which caused their generation has been removed. Thus H. Lamb[21] has shown that currents generated in a copper sphere of the size of the earth would take about 3 million years to die to one-third of their value after the source of electromotive force was removed. A somewhat similar situation exists in relation to a sudden destruction of an initial state of permanent magnetization. Thus if a sphere of the size of the earth were originally magnetized and the state of magnetization were destroyed, for example, by a sudden rise of temperature, the change of magnetic flux attending the destruction of the magnetization would set up induced currents which would tend to perpetuate the field to such an extent that in the case of a conductivity comparable with copper, about 3 million years would elapse before the field due to the sphere at a point had sunk to a value comparable with one-third of its original value[22]. Suggestive as are these considerations in tempting us to see in them the origin of currents which would account for the earth's magnetism we have to realize the great improbability of a conductivity of the earth's interior sufficient to provide for the necessary requirements. Data as to the conductivity of the earth's interior drawn from considerations based on the theory of the diurnal variation suggest a value so small as to insure that such current as the above would fall to one-third of their original values in two or three days.

A possible source of maintenance of internal currents has been suggested by Lamor[18], chiefly in reference to an explanation of the magnetic field of the sun. If there is any internal circulation of matter in meridional planes and if we start with an initial magnetic flux parallel to the polar axis, the flow will set up induced currents in circles parallel to the equator. If the initial magnetic flux is in the right direction in relation to the circulation, the induced currents set up will increase the original field, so that a finite field may become produced in this manner from infinitesimal beginnings, as in the case of a self exciting dynamo, the energy coming, of course, from the internal circulation. On such a view, the secular variation would have to seek its origin in a secular periodicity in the internal circulatory motion.

The enormous amount of positive and negative electricity in the earth tempts us to seek in strange places for possibilities as regards a residual current which might result from a slight difference in their velocities. Thus, if the free electrons in the earth were *absolutely* free, and if the remainder of the substance of the earth were dying down in velocity, for example as a result of total friction, and if the causes responsible for the decay of motion operated only on the part of the matter other than the free electrons, the latter would continue to revolve with undiminishing velocity, and as time went on a large current would result from

the relative motion of these electrons and the remainder of the earth's substance. In practice, the relative motion would only grow until the drag due to friction—in this case, electrical resistance—which resulted from the relative velocity was sufficient to bring about the continual destruction of momentum of the electrons as a result of their continual loss of velocity. On submitting the matter to calculation we find that, for the specific resistance of the earth's core as calculated from diurnal variation considerations, it would be necessary for the earth to lose practically the whole of its angular velocity in a very small fraction of a second in order that the electric current set up as a result of the drag should be sufficient to account for the earth's field.

The argument for the foregoing consideration is as follows: Suppose σ is the specific resistance of the material of the earth, e the electronic charge, and m the mass. Then, if i is the electric current density sought, and if v is the tangential velocity of the earth at the point in question

$$\sigma ie = -m\frac{dv}{dt}$$

$$\frac{1}{v}\frac{dv}{dt} = \frac{\sigma ie}{mv}.$$

Putting $\sigma = 0{\cdot}3\times10^{13}$ e.m.u.[11], $i = 4\times10^{-10}$ e.m.u., $e/m = 1{\cdot}7\times10^7$, and $v = 5\times10^4$, we find

$$-\frac{1}{v}\frac{dv}{dt} = 4\times10^5 \text{ nearly.}$$

Even had the specific resistance been as low as that of copper, viz $0{\cdot}7\times10^3$, we should have found

$$-\frac{1}{v}\frac{dv}{dt} = 8\times10^{-5},$$

and it would have been necessary for the earth to lose practically the whole of its velocity in less than a day in order to give rise to a magnetic field comparable with that of the earth.

Quite apart from considerations invoking a finite rate of decay in the earth's rotation, it is not out of the realm of possibility that the mere rotation itself may bring about a condition in which there is a relative motion between the free electrons and the remainder of the matter It may not even be necessary to provide a source of power to maintain the relative motion in opposition to electrical resistance; for, such a state of relative motion may be the state of equilibrium which must be attained in order that there shall be no dissipation of energy. The elements which enter in this connection are those associated with the mechanism by which electrical conductivity arises in a metal and there are certain not unreasonable hypotheses which would provide for conditions of this kind[17]. However, any attempt to account for the earth's magnetism along these lines must necessarily be highly speculative.

Magnetization of Rotation.—If we believe that the atoms of which the substance of the earth is composed are magnetic, and that this magnetic condition arises from the rotation of electrons in the atom, we should expect the atoms to act like gyroscopes and tend to turn with their axes parallel to the axis of the earth's rotation, this effect in favour of organized orientation being opposed by the temperature agitation of the molecules. However, a phenomenon of this kind makes the intensity of magnetization independent of the size of the sphere for a given angular velocity[17], so that if it were a potent factor in the case of the earth's magnetism, the effect would be very readily observable in the case of small bodies set into rotation in the laboratory. The magnetization produced by rotation has been experimentally measured by S. J. Barnett, and both calculation and experiment alike show that even in the most favourable case, that of an earth with an iron core, we could not expect to realize a magnetic field more than about 10^{-10} for the earth's magnetic field.

It has sometimes been suggested that a very weak magnetizing intensity, either of the nature of a magnetic field of unknown origin or of a dynamical nature such as the gyroscopic action just discussed might, in the presence of an abnormally large permeability, result in an intensity of magnetization comparable with that of the earth. Such might indeed be the case for a long cylindrical body; but, in the case of a sphere magnetized to an intensity I, there is within the sphere a demagnetizing field equal to $I/3$, resulting from the so-called fictitious distribution of positive and negative magnetism on the two hemispheres (this fictitious distribution being of course, as regards its action, the representative of all the molecular magnets of which the sphere is composed) Thus, to be effective, any magnetizing influence, magnetic or otherwise, must be such as to exert on the molecule a couple equal to that exerted by a magnetic field equal to one-third of the resultant magnetic intensity to be produced in the sphere.

Possibilities of Modifications in Classical Electrodynamics.—The fact that the positive electricity and the negative electricity in the earth, taken by themselves, produce by their rotations such enormous magnetic fields tempts us to inquire whether some slight modification in classical electrodynamics may be made which would permit a lack of complete compensation between the effects of the electricity of opposite sign and leave the observed magnetic field as a residual. We have already discussed one such possibility under *Possibilities of a modification of laws of force between electric charges;* but although the idea there involved was comparatively simple, the result was secured at the expense of conformity with the theory of relativity By adopting a rather more radical modification of the electrodynamic laws[23], but one consistent with the theory of relativity, it has been found possible to provide for a situation in which, while the laws for the fields due to negative electricity are unaltered, the modified equations demand a contribution to the magnetic field produced by the positive electricity as a result of the acceleration, rate of change of acceleration, etc., which it experiences in its rotation, a contribution non-existent in the case of the negative electricity. The superposed distributions no longer cancel as regards magnetic field and a residual is provided for. Moreover, the modification of the laws demanded for the positive electricity is a violation of the equation of continuity, so that positive electricity is gradually destroyed as a result of the rotation, with a result that the surplus negative electricity piles up until it has created a potential gradient in the atmosphere sufficient to insure its departure into space at a rate which balances its accumulation. (*See* ELECTRICITY: *Atmospheric*) Finally, the modification contains a provision for a difference between the force between like and unlike charges which provides for gravitation in a manner roughly analogous to that described in section *Possibilities of a modification of the laws of force between electric charges.*

The modifications necessary in the fundamental laws are extremely small in magnitude for such accelerations, etc , as are concerned in the earth's rotation. Thus, for example, the modification in the equation of continuity corresponds to a disappearance of only 0·5 per cent of the earth's mass in 10^{20} years, and the difference between the force of attraction between like units of electricity and the force of repulsion between unlike units amounts to less than one part in 10^{36}.

The form of the modification is adjusted so as to secure the correct ratio of the magnetic field of the earth to that of the sun and to predict an almost negligibly small magnetic field for a body of laboratory dimensions rotating at the highest attainable speed. It must be remarked, however, that the value of comparison with the sun is largely diminished on account of entirely different conditions and nature of the magnetic field to be found on that body. In one form of the theory, the expression for the magnetic field as a function of the angular velocity and size of the rotating body leads to the conclusion that magnetic fields of the known order 2,000 gauss may be expected in sunspots provided that in the spots, the solar gases may be supposed in rotation with the not unreasonable peripheral speed of 80 kilometers per second.

A brief outline of the details of the theory is as follows: The electromagnetic equations,

$$(A)\ \frac{\rho\mathbf{u}}{c} = \frac{1}{c}\frac{\partial\mathbf{E}}{\partial t} + \text{curl}\,\mathbf{H},\quad (C)\ 0 = \frac{1}{c}\frac{\partial\mathbf{H}}{\partial t} + \text{curl}\,\mathbf{E},$$

$$(B)\ \rho = \text{div}\,\mathbf{E},\qquad (D)\ 0 = \text{div}\,\mathbf{H},$$

together with a force equation of the form

$$(H)\ \left(\mathbf{E}+\frac{[\mathbf{w}\cdot\mathbf{H}]}{c}\right)e=\frac{d}{dt}(m_o k\mathbf{w}),$$

with $k=\left(1-\frac{\mathbf{w}^2}{c^2}\right)^{-\frac{1}{2}}$ are taken as a basis from which to generalize.

The equations corresponding to $(A)-(D)$ are left unchanged for the fields due to negative electricity; but for the fields due to positive electricity they are generalized in the following way:— The 4-vector $\rho\mathbf{u}$, ρic associated with (A) and (B) is replaced by a more general 4-vector $\mathbf{S}$, $ic\mathbf{S}_t$, given by

$$(I)\ \mathbf{S}=\rho_+\mathbf{u}_++\alpha k_+ d\frac{(\rho_+\mathbf{u}_+)}{dt}+\beta k_+\frac{d}{dt}k_+\frac{d}{dt}(\rho_+\mathbf{u}_+)=\rho_+\mathbf{u}_++\alpha\mathbf{P}+\beta\mathbf{Q},$$

$$(J)\ \mathbf{S}_t=\rho_++\alpha k_+\frac{d\rho_+}{dt}+\beta k_+\frac{d}{dt}k_+\frac{d\rho_+}{dt}=\rho_++\alpha\mathbf{P}_t+\beta\mathbf{Q}_t$$

where α and β are invariants of the Lorentzian transformation, and the $\mathbf{P}$'s and $\mathbf{Q}$'s have the values defined in (I) and (J). The additional terms in (I) and (J) destroy the equation of continuity, the only one appreciably operative in this respect for uniform rotation being $\alpha\mathbf{P}$. By an appropriate choice of α we can make this term give rise to a slow death of positive electricity (amounting to a loss of 0·5 per cent of the earth's mass in 10^{20} years) such as to leave a continually increasing surplus of negative which, after building up the necessary electric field, passes off continually, as the atmospheric electric current, by conduction through the atmosphere.

The generalized equations lead, very approximately, to the same expressions for the fields as are given by the classical theory, except that the $\rho_+\mathbf{u}_+$ and ρ_+ of classical theory are replaced by $\mathbf{S}$ and $\mathbf{S}_t$. Thus, in the case of a rotating neutral earth there is a fictitious current density $\alpha\mathbf{P}+\beta\mathbf{Q}$ and a fictitious charge density $\alpha\mathbf{P}_t+\beta\mathbf{Q}_t$. The value of α chosen as above is too small to make appreciable contribution to the fictitious current density. The fictitious current density is provided for by $\beta\mathbf{Q}$, and the choice of β necessary to result in a magnetic field equal to that of the earth is such that, as regards any fictitious charge density of importance in its power to give rise to the earth's electric field, the term $\beta\mathbf{Q}_t$ is negligible, as is also the term $\alpha\mathbf{P}_t$. The electric field is provided for otherwise, as outlined above.

The forms of the invariants α and β are chosen so that the theory gives the correct ratio for the magnetic field of the earth to that of the sun, and predicts for a small sphere of laboratory size, rotating at the highest attainable speed, a magnetic field and a rate of death of charge which would be immeasurable, or measurable only with considerable difficulty.

Gravitation is provided for by a replacement of the force equation by two equations, for the motions of positive and negative electrons respectively, the modification implying, primarily, a difference in the forces between equal like charges and equal unlike charges.

Magnetic Field of the Sun.—The magnetic field of the sun is of particular interest in relation to theories of terrestrial magnetism; for, in the sun and earth we are presented with bodies of entirely different size, angular velocity, and physical condition. In addition to strong magnetic fields of the order of 2,000 gauss which are to be found in sunspots, the sun possesses a general magnetic field similar in some respects to that of the earth, but with very important differences.

The Zeeman effect affords a means of measuring the magnetic intensity at different levels in the sun's atmosphere. Measurements extend from altitudes of 250 kilometres to 450 kilometres above the sun's disc, and show a remarkably sharp decline in value from 50 gauss for the former altitude to 10 gauss for the latter. If the magnetic field of the sun were anything like that of a uniformly magnetized sphere, the field would vary as the inverse cube of the distance from the sun's centre, and would change by only about 0·1 per cent between the altitudes cited.

The direction of the sun's magnetic field at a point bears the same relation to the direction of rotation as in the case of the earth, and the magnetic axis of the sun is inclined at an angle of about 5° to the axis of rotation. The magnetic axis, moreover, exhibits a rapid "secular" variation consisting of a rotation in the opposite direction to the rotation of the sun, with a period of about eight months.

THEORIES OF MAGNETIC IRREGULARITIES AND VARIATION

Magnetic Irregularities.—The difficulties of accounting for the larger irregularities of the earth's field are bound up with our lack of knowledge of the composition of the earth's crust to any considerable depth. Local irregularities can in most cases be assigned to local deposits of magnetic material. An ingenious attempt to ascertain the general nature of the conditions necessary to provide for the main features of the earth's magnetic abnormalities was made by Wilde[24)], who constructed a "magnetarium" designed to reproduce the main features of the earth's field and also its secular variation. Wilde's magnetarium consisted of a globe 18 inches in diameter provided with plates of iron attached to its under side beneath the oceans, and in one or two other locations. Within the sphere, and fastened to it, was a spherical shell of wire gauze supporting a current winding with its planes parallel to the equator. Within the gauze shell was mounted a smaller sphere which could be made to revolve about an axis inclined at 23·5° to the axis of the first sphere, and which was wound with wire in planes perpendicular to its axis of rotation. Wilde's views have not passed without criticism. However, a consideration of the depth to which the probable temperatures conditions within the earth would permit iron to exist in magnetizable form, combined with the effect of the ocean areas in modifying the temperature gradient, and the requirements imposed by the hypothesis of isostasy lend support to reasonableness of the condition suggested by the magnetarium, as regards their application to the larger irregularities[11)]. The part of Wilde's conclusions having to do with currents circulating within the earth, and with the secular variation must necessarily remain more speculative.

Theory of the Diurnal Variation.—The fundamental idea underlying the cause of the diurnal variation is undoubtedly that originated by Balfour Stewart. According to this view, the motion of the earth's upper atmosphere under the influences of the tides sets up electromotive forces on account of the cutting of the earth lines of force by the moving air. These electromotive forces set up currents in the atmosphere in regions where the conductivity is sufficient and these currents, varying as they must with the tides, produce magnetic fields which also partake of the tidal periods. In addition to the direct effect of the atmospheric currents, induced in the above manner, there is a secondary effect caused by the induced currents which the time rates of change of the atmospheric currents set up in the substance of the earth. According to S. Chapman[7)], these currents induced in the earth contribute about 28 per cent of the total diurnal variation.

The two bodies chiefly concerned in producing the atmospheric motions which are the origin of the diurnal variation are the sun and the moon. If we first confine our attention to the variation of the magnetic elements throughout the lunar day, averaging the results for any (lunar) time of day throughout one or more months, and if we plot the results so obtained against the time, we find that the curves are symmetrical in horizontal intensity north and south of the equator, and anti-symmetrical in declination and (outward) vertical intensity. All the curves are purely semi-diurnal in type. These features are accounted for by the assumption that the atmospheric motions are of the lunar tidal type. The barometer indicates semi-diurnal variations in atmospheric pressure indicating the existence of an atmospheric lunar tide, and this must involve a circulation of the air, the flow being mainly horizontal[11)]. It is consequently the earth's vertical component of magnetic intensity which is mainly concerned in the production of the electric currents in the conducting regions of the atmosphere. An element of lack of harmony between theory and observations appears, however, in a numerical comparison of the phase of the magnetic diurnal variation and

that of the oscillations in barometric pressure[11].

If, instead of plotting the means for one or more lunar months, we plot the data for the individual lunar days, the curves obtained are more complicated than those constructed from the monthly means In a general way the complication is in the direction of a magnification of the magnetic variations during the daytime. On plotting the magnetic elements throughout the solar day, using for this purpose a number of the quietest days for the month, we obtain curves which have many features in common with those obtained by plotting against time for the lunar day, but the amplitudes are about eleven times those for the lunar day. This is in harmony with the expectations arising from the barometric variation, which, for observations plotted throughout the solar day, indicate amplitudes of tidal motion fifteen times those obtained by plotting the monthly averages throughout the lunar day. It is probable that the atmospheric motions associated with the sun have their origin in temperature differences rather than in ordinary tidal forces; for, if this were not the case, the lunar variation of barometric pressure should be greater than the solar variation, since the purely tidal influence of the moon is about twice that of the sun.

The inferences to be drawn from terrestrial magnetism as regards the conductivity of the upper atmosphere have been summarized under ELECTRICITY. *Atmospheric*

Magnetic Storms.—One of the first attempts to explain magnetic storms attributed them to the magnetic fields produced by streams of charged particles emanating from the sun; but, as pointed out by Schuster, such theories are untenable because the natural repulsion of the parts of such a stream would prevent its arriving at the earth in sufficiently concentrated form S Chapman[25] has shown that the most characteristic features of magnetic storms may be explained by supposing that they are produced by atmospheric currents set up as a result of the cutting of the earth's horizontal component by a radial motion of an atmospheric conducting layer The magnetic phenomena suggest a radial motion inwards at the commencement of the storm, followed by an outward radial motion. In the original form of Chapman's theory the primary agency responsible for the storm was a stream of alpha particles from the sun, the outward radial motion resulting from the subsequent mutual repulsion of the positive charges Lindemann[26] has criticized the theory in this form on the grounds that a stream of alpha particles of the necessary strength would imply an unwarrantedly large radio-activity in the sun, and that further, a stream of the necessary intensity could not hold itself together against self-repulsion in its journey from sun to earth Lindemann himself has suggested as the origin of these storms, groups of positive and negative particles shot out from the solar prominences under the influence of the pressure of light As a matter of fact, actual observations of the rate of growth of solar prominences indicate that the gases in these cases attain velocities of the order of 10^8 cms per second, and this velocity is sufficient to make reasonable the assumption of their journey from sun to earth without serious recombination. The neutrality of the stream as a whole would provide an escape from the difficulties inherent in self-repulsion Lindemann supposes that the negative ions may be lighter than the positive, so that the former are stopped in the outermost regions of the atmosphere, while the positive ions penetrate deeper down and are responsible for auroral phenomena.

If, as is likely to be the case, the positive ions were hydrogen atoms or molecules, they would be lighter than the molecules to which the electrons attach themselves on their impact with the outer atmosphere. The subsequent attraction of the positive and negative ions would consequently result in an outward motion of the negative ions which would be more rapid than the inward motion of the positive ions The net result would be that, following the initial effects due to the influx of the stream, there would be the equivalent of an outward flow of gas, and this gas cutting across the horizontal component of the earth's field would give rise to the type of atmospheric currents necessary to account for the most characteristic features of magnetic storms[11].

Of course, the earth's magnetic field would act independently on the two oppositely charged portions of the neutral stream of particles, tending to separate them, but with a sufficiently intense beam this tendency to separate would become almost immediately compensated by the electrostatic field resulting from the separation, so that the beam as a whole would travel practically uninfluenced by the earth's magnetic field The facts associated with the aurora do demand a concentration of ionizing towards high latitudes, however, so that it would seem difficult to avoid the conclusion that there is an excess charge of one sign in the material radiations from the sun, unless, indeed, it is possible to formulate a condition, satisfying the mathematical requirements and in which the magnetic field of the earth bends the paths of both the positive and negative particles in such a manner as to result in a concentration in the auroral zones without there being necessarily a large excess density of one sign anywhere. In this connection it must be remembered that the path of a charged particle may be bent completely around the earth, so that it is not out of the realm of possibility that in spite of the fact that the positive particles are bent in opposite directions to the negative by the magnetic field, there may exist a general intermixing and intersection of orbits of oppositely charged particles such as to reduce greatly the electrostatic fields which would otherwise be set up in the absence of such conditions

(W. F G. S)

TERRISS, WILLIAM (1847–1897), English actor, whose real name was William Charles James Lewin, was born in London on Feb 20, 1847. After trying the merchant service, medicine, sheep-farming in the Falkland isles, and tea-planting in Bengal, in 1867 he took to the stage He quickly came into favour, and appeared at the principal London theatres from 1868 onwards. In 1880 he joined Irving's company at the Lyceum, playing such parts as Cassio and Mercutio. He was then engaged to take the leading parts in Adelphi melodrama. His last appearance was in *Secret Service* On Dec 16, 1897, as he was entering the Adelphi theatre, he was stabbed to death by a madman, Richard Prince. Terriss married Miss Isabel Lewis, and his daughter Ellaline Terriss became a well-known actress in association with her husband Edward Seymour Hicks (b 1871).

See Arthur J. Smythe, *The Life of William Terriss* (1898).

TERRITORIAL ARMY. The end of the nineteenth century saw a situation very similar to that at the end of the eighteenth century The possibility of this country's being engaged in a major war, and fear that an enemy would attempt an invasion of the British Isles. Like so many British institutions, the army grew with its own momentum, encouraged in differing degrees, its organization not proceeding with its growth. The Royal Commission of 1904 laid stress on the fact that organization for war

was almost non-existent, and concluded with the unanimous opinion that from these and other defects of education and training, the force was not qualified to take the field against the troops of a Continental army (Report of Royal Commission on the Militia and Volunteers, 1904, paragraphs 35–49, 57, 58).

The military forces of the Crown in 1906 comprised the first line, or regular army; the second line was provided by the Militia; the third line consisted of the volunteers and yeomanry. The third line was separately organized from the other two, and owing to a disbelief in its value was given no permanent place in any scheme for using the available military resources of the nation in the event of war.

Such was the situation which faced Lord Haldane and his advisers in 1907; how well the reorganization was done may be shown by the words written by Earl Haig on the fly-leaf of a copy of War Despatches given by him to Lord Haldane on Peace Day:—

"In grateful remembrance of his successful efforts in organizing our Military Forces for a war on the Continent."

The reorganization of the Army of 1908 retained the regular army, reorganized into six Divisions and four cavalry brigades and the necessary army troops as the first line; changed the militia into the "special reserve" with the duty of finding and training drafts for the first line, the territorial force becoming the second line.

The Territorial Force was for home defence, but within itself contained a "special service section," men of which volunteered to occupy posts outside the United Kingdom vacated by the regular army, or to serve within the United Kingdom for purposes of defence whether the territorial force be embodied or not. The T.F. was organised on a county basis, and of necessity additional units were raised to complete the new arms or services, whilst redundant units, particularly infantry, were either disbanded or reconstituted into units of a different arm.

Before 1908, the universities and many public schools had volunteer corps attached to the local volunteer unit. These were transformed into an "officers' training corps" administered direct by the War Office, a far reaching change, as the World War proved.

Administration and Training of the territorial force were separated, officers commanding units being no longer personally responsible for the finances of their units. County territorial force associations for each county were formed under the presidency of the Lord Lieutenant, consisting of representatives of the county and borough Councils, the territorial units of the county and certain co-opted members. The duty of these associations was to raise and equip the men, provide accommodation, and generally relieve the units of all details and other responsibilities outside training. The Under Secretary of State for War was given the direct responsibility for this side of the work, and a territorial directorate was established at the War Office under his direction. The training remained the responsibility of the military authorities.

The Fear of Invasion.—Six months of training were considered necessary after mobilization before the force could take the field overseas, and liability for service overseas was not insisted upon. The possibility of an invasion of the British Isles was always in the mind of the nation; the functions of the territorial force were therefore to supply garrisons for naval and other fortresses; to repel raids; and, by voluntary agreement to furnish units for the expansion of the Expeditionary Force.

The World War.—So 1914 found the Territorial Force. On the outbreak of the World War, Lord Kitchener, who assumed control at the War Office, realized that the existing military forces would not be sufficient, the territorial force being without reserves, and in his scheme of expansion discarded the county system that had been built up, and raised and trained the New Armies.

Soon after the outbreak of the war there were urgent demands for reinforcements in France, and territorial units volunteered readily for overseas service. In his dispatch dated Nov. 20, 1914, which covered the period Oct. 8 to Nov. 20, 1914, Field Marshal Sir John French reported:—

"In the period covered by this despatch territorial troops have been used for the first time in the army under my command. The units actually engaged have been the Northumberland, Northamptonshire, North Somerset, Leicestershire and Oxfordshire Regiments of Yeomanry cavalry; and the London Scottish, Hertfordshire, Honourable Artillery Company and the Queen's Westminster battalions of Territorial Infantry.

"The conduct and bearing of these units under fire, and the efficient manner in which they carried out the various duties assigned to them, have imbued me with the highest hope as to the value and help of Territorial Troops generally."

By Dec. 1 2,413 officers and 66,805 other ranks of the territorial army had gone overseas (the 42nd division had proceeded to Egypt and the 43rd and 44th divisions to India, to take over garrison duties, and so permit the regular units to be relieved for active service).

As a complete territorial division, the 46th (North Midland) division was the first to proceed overseas to a theatre of war; by August 1915 the whole of the original fourteen territorial divisions were overseas, and towards the end of the war there were 21 territorial divisions in the various theatres of war, whilst to the end, one mounted and four infantry territorial divisions were maintained in this country for its defence against invasion.

There has been much controversy over the question whether it was wise that expansion of the military forces of Great Britain should be made through the medium of the "new armies" instead of through the existing organization of the territorial force, but there was a difficulty in the fact that the territorial soldier, unless he voluntarily offered, was not available for service overseas. Time showed that the territorial soldier was willing and eager to pull his full weight, but the decision had to be made before such knowledge was available.

In France, Flanders, Salonika, Gallipoli, Palestine and Mesopotamia territorial divisions served, whilst in India, Egypt, Malta and Gibraltar garrison duty was done, thus relieving regular units. The fourteen first line divisions served as complete divisions overseas in war areas—they were numbered consecutively from 42nd to 56th (except the 45th, a second line division) inclusive, and in addition eight, the 45th, 57th to 62nd, and 66th, second line territorial divisions served overseas. As the war went on, yeomanry units were amalgamated and formed the 74th division which also served overseas.

Reconstruction in 1920.—Demobilization saw the Territorial Force dispersed; all that remained were rolls of officers in the Army List. But the territorial force had proved its value, and the principle was accepted that in the event of any future war on a national scale, the territorial army would be the basis of expansion—the word "force" being dropped in the new scheme, and "army" substituted. In February 1920, the territorial army was reconstructed. The fourteen divisions were maintained, and as time went on various alterations from its pre-war constitution were made. One important truth was accepted, that the defence of these islands is overseas, and to-day, every man joining the territorial army signs up for overseas service. It is now organized on almost identical lines with the regular army, new units such as signal and armoured car companies being introduced by conversion from the yeomanry, which has been reduced from 14 Brigades to 2 Brigades. As the air is now so important a factor, territorial air squadrons, and their opposite numbers, air defence brigades, have been formed.

The territorial army to-day can truly be said to be a basic part of the military forces of the country. The training, too, has reached a far higher standard than before the war. At the army manoeuvres of 1925, the 162nd Infantry Brigade (T.A.) was selected to represent the territorial army, and met with the commendation of the Secretary of State for War who stated that the territorial soldier had proved himself indistinguishable from his comrade of the regular army.

Plans for Co-ordination.—It has been stated in Parliament that the territorial army is to be the basis of expansion of the British fighting forces in the event of a national war, although the exact method of such expansion has not yet been definitely announced. There is a handicap in the fact that the unit of organisation of the army is the division while the existing organisation

of territorial army associations does not coincide with this.

Associations to-day are formed on the basis of local administrative areas with the county as the unit, but this is hardly ideal from the military point of view. The territorial army is actually made up of individual citizens recruited in the main from the larger centres of population. The main centres of population in many cases do not coincide with the county boundaries and communications whether by road or rail give a community of interest between towns which in many cases are situated in different counties. The old pride of "county" even has largely given place to the pride of town

In view of the impending changes in military organisation, it may well be asked whether this would not be an opportune time to consider the question of the redistribution of the responsibilities of associations to make them coincide with the military distribution. Such a change would undoubtedly be a great advantage in the event of a general mobilization and the expansion that would be necessary. The division might be the main area, with, in widely extended areas, a brigade area as the minimum unit of administration. This would permit, by the amalgamation of offices, the payment of salaries adequate to ensure only first class men being appointed, and would tend to prevent the confusion and duplication that frequently occurred at the outbreak of the World War

Territorial Associations consist of representatives of local authorities, co-opted members, and military members The latter form the majority and must be serving or have served with the territorial army or its predecessor. To ensure a full appreciation of current problems the military members should be nominated by the units through the ordinary military channels, the representative members already being nominated by the units they represent.

Mechanism.—No study of the territorial army to-day can be complete without considering the influence that the advent of mechanization is likely to exert. The territorial army would benefit by mechanization and would improve in efficiency in a greater degree than even the regular. Life to-day is centred round industry and at their daily work men are brought into continual contact with machines, whilst in their leisure the car and motor bicycle are almost universally used; this means that a portion of the training required is already in the possession of the potential recruit and experience has shown that mechanical units attract a high class of recruit

Training.—Although during the war and since the value of the territorial army has been acknowledged, in some quarters the view still lingers that the territorial army is not equal to the task required and that the territorial soldier cannot rise to the higher commands. This view is contradicted by history with its numerous examples of the success of armies composed of and commanded by citizen soldiers There is no race in which the individual takes more quickly to the work of war than the people of the British Empire, and if the mistakes, under-valuation, and friction of the past are not to be repeated it is essential that the liaison between the regular and territorial armies should become more complete.

Liaison will not be complete until the two are in reality, not merely in name, branches of one army. To this end all avenues must be explored

Distinction in Character.—With a sympathetic co-operation between the professional and amateur soldier the territorial army can undoubtedly attain and maintain such a state of efficiency that in the event of a fresh national emergency, the country will have a second line on which full military reliance can be placed. But it is well to emphasize that the only territorial soldier who is of value is the one who joins because soldiering appeals to him.

Much of the regular army's life is devoted to duties and ceremonial which have no place on the battlefield; all such work is unnecessary and even irritating to the territorial soldier who has joined for the "pure" soldiering life, and is anxious to learn. And as, at the same time, the annual training is usually his annual holiday, he does not view with satisfaction unnecessary restrictions such as evening passes out of camp, the surveillance of pickets and regimental police, and curfew—like "lights out" at an hour reminiscent of a schoolboy's bedtime. Experience, indeed, has shown that with the citizen soldier discipline is improved by the removal of restrictions which impair his self-respect and serve no practical purpose. (J Br.)

TERRY, EDWARD O'CONNOR (1844–1912), English actor, was born in London, and began his stage career in the provinces. Between 1868 and 1875 he was the leading comedian at the Strand theatre, London. He joined Hollingshead's company at the Gaiety in 1876 and became a public favourite in the burlesques produced there during the next eight years, his eccentric acting and singing having many imitators. In 1887 he went into management, opening Terry's theatre, where his production of Pinero's *Sweet Lavender* was a notable success. Subsequently he was best known on many tours in the provinces and in Australia, America and South Africa. Off the stage he was well known as an ardent Free-mason, and an indefatigable member of the councils of many charities and of public bodies.

TERRY, ELLEN ALICIA (1848–1928), English actress, was born at Coventry on Feb. 27, 1848. Her parents were well-known provincial actors and close friends of the Keans. Her sisters Kate, Marion and Florence, and her brother Fred, all joined the theatrical profession Her own first appearance on the stage was made on April 28, 1856, under the Keans' management, as the boy Mamilius in *The Winter's Tale,* at the Princess's theatre, London Two years later she played Prince Arthur in *King John* and won high praise From 1860 to 1863 and again from 1867 to 1868 she acted with various stock companies On Dec. 26, 1867 she played for the first time with Henry Irving, being cast as Katharine to his Petruchio in Garrick's version of *The Taming of the Shrew* at the Queen's theatre When quite a girl she married G F. Watts the painter, but the marriage was soon dissolved. Between 1868 and 1874, having married E. A. Wardell, an actor whose professional name was Charles Kelly, she was again absent from the stage, but reappeared at the Queen's theatre under Charles Reade's management On April 17, 1875, she played Portia in a revival of *The Merchant of Venice* under the Bancrofts' management at the old Prince of Wales's theatre. A succession of smaller triumphs at the Court theatre culminated in her beautiful impersonation of Olivia in W. G. Wills's dramatic version of Goldsmith's *Vicar of Wakefield,* in 1878, the result of which was her engagement by Henry Irving as his leading lady for the Lyceum and the beginning of a long artistic partnership, in the success of which Ellen Terry's enchanting personality and fine aesthetic sense played a large part. Her Shakespearean impersonations at the Lyceum were Ophelia in 1878, Portia in 1879, Desdemona in 1881, Juliet and Beatrice in 1882, Viola in 1884, Lady Macbeth in 1888, Katherine, in *Henry VIII*, and Cordelia in 1892, Imogen in 1896, and Volumnia, in *Coriolanus,* in 1901. Other notable performances were those of the Queen in Wills's *Charles I* in 1879, Camma in Tennyson's *The Cup* in 1881, Margaret in Wills's *Faust* in 1885, and the title-part in Charles Reade's one-act play *Nance Oldfield* (1893), Rosamund in Tennyson's *Becket* (1893), Madame Sans-Gêne in Sardou's play (1897), and Clarisse in *Robespierre* (1899) With the Lyceum company she several times visited the United States. In 1902, while still acting with Sir Henry Irving, she appeared with Mrs. Kendal in Beerbohm Tree's revival of *The Merry Wives of Windsor,* at His Majesty's theatre, and she continued, after Sir Henry Irving's death, to act at different theatres, notably at the Court theatre (1905) in some of Bernard Shaw's plays. In 1906 her stage-jubilee was celebrated in London with much enthusiasm, a popular subscription in England and America resulting in some £8,000 being raised. In 1907 Miss Terry married James Carew, an American actor.

In 1922 she was granted the honorary degree of LL.D (St. Andrews); and in 1925 she received the Grand Cross of the Order of the British Empire. Dame Ellen Terry's 80th birthday was celebrated in February 1928, when an interesting reminiscent correspondence appeared in the *Times.* On the following July 21 she died, after a short illness, at Small Hythe, near Tenterden, Kent. Sir Johnston Forbes Robertson has said of her: "Everything she did was invested with great charm. I do not suppose

there ever was such an Ophelia. Nor do I think there ever will be again. In the theatre she was adored. In the public estimation she became a fetish. Take her for all in all she is one of the most remarkable figures in the history of the stage." In 1908 she published her only book, *The Story of My Life.*

See Charles Hiatt, Ellen Terry and her Impersonations (1898); Clement Scott, *Ellen Terry* (1900).

TERRY, SIR RICHARD RUNCIMAN (1865–), knighted 1922, British organist and choir-director, was born at Ellington, Northumberland, the son of Thomas Terry of Newcastle-on-Tyne, and obtained a choral scholarship at King's College, Cambridge. After acting as organist and choirmaster at Elstow School (1890); St. John's Cathedral, Antigua, West Indies (1892); and at Downside Abbey near Bath (1896), he became organist and director of the Roman Catholic Cathedral, Westminster, London (1901–24). His great service to English music is twofold: he studied and revived the beautiful church music of the English composers of the 17th century, and by the finished performances at Westminster of the works of these and the Italian composers brought about a revolution in church services in England, even outside his own communion. He was the composer of five Masses and other music, and the author of *Our Church Music* (1901); *Catholic Church Music* (1907); *Tudor Church Music* (1922); *On Music's Borders* (1927); etc. He also compiled the *Westminster Hymnal* and published a collection of shanties in *The Shanty Book* (pt. I. 1921, pt. II. 1926).

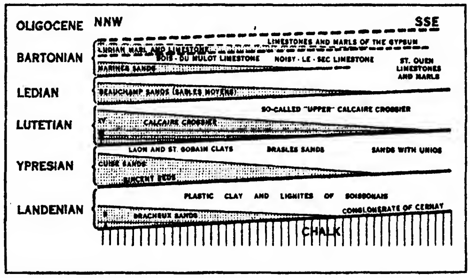
TERTIARIES, associations of lay folk in connection with the Mendicant Orders. The old monastic orders had had attached to their abbeys confraternities of lay men and women, who were made partakers in all the religious exercises and other good works of the community to which they were affiliated, and they were expected in return to protect and forward its interests; but they were not called upon to follow any special rule of life. The institution of Tertiaries arose out of the Franciscan movement. It seems to be certain that St. Francis at the beginning had no intention of forming his disciples into an Order, but only of making a great brotherhood of all those who were prepared to carry out in their lives certain of the greater and more arduous of the maxims of the Gospel. The formation of the Franciscan Order was necessitated by the success of the movement and the wonderful rapidity with which it spread. When the immediate disciples of the saint had become an order bound by the religious vows, it became necessary to provide for the great body of laity, married men and women, who could not leave the world or abandon their avocations, but still were part of the Franciscan movement and desired to carry out in their lives its spirit and teaching. And so, probably in 1221, St. Francis drew up a Rule for those of his followers who were debarred from being members of the order of Friars Minor. At first they were called "Brothers and Sisters of the Order of Penance"; but later on, when the Friars were called the "First Order" and the nuns the "Second Order," the Order of Penance became the "Third Order of St. Francis"—whence the name Tertiaries. Immediately on its establishment in 1221 the Third Order spread with incredible rapidity. Everywhere it was connected closely with the First Order, and was under the control of the Friars Minor.

In time a tendency set in for members of the Third Order to live together in community, and in this way congregations were formed who took the usual religious vows and lived a fully organized religious life based on the Rule of the Third Order with supplementary regulations. These congregations are the "Regular Tertiaries" as distinguished from the "Secular Tertiaries," who live in the world, according to the original idea. The Regular Tertiaries are in the full technical sense "religious," and there have been, and are, many congregations of them, both of men and of women. In 1883 Leo XIII. caused the rule to be recast and made more suitable for the present day.

There can be little doubt, whatever counter-claims may be set up, that the Third Order was one of St. Francis' creations, and that his Third Order was the exemplar after which the others were fashioned; but at an early date the other Mendicant Orders formed Third Orders on the same lines, and so there came into being Dominican Tertiaries, and Carmelite, and Augustinian, and Servite, and also Premonstratensian, together with a large number of others.

Bibliography.—The most serviceable authority on the Franciscan Tertiaries is probably Max Heimbucher, *Orden und Kongregationen* (1907), ii. §§ 103, 104, 105, where an ample bibliography is supplied. The same work gives information on the other Tertiaries at the end of the sections on the various Orders. *See* also the *Catholic Encyclopaedia*, art. "Tertiaries"; Adderley and Marson, *Third Orders* (1902); Tachy, *Les tiers Ordres* (1897).

TERTIARY, in geology, the third of the great time divisions or eras distinguished since the appearance of clearly recognisable forms of life on the globe. It succeeds the Secondary or Mesozoic

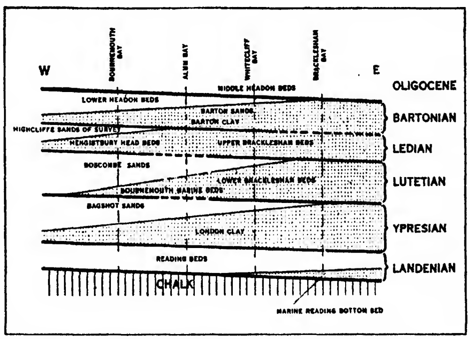


FROM "GEOLOGICAL MAGAZINE" (DUNLAU & CO.)

FIG. 1.—CYCLES OF SEDIMENTATION IN THE PARIS BASIN

era and is followed by the Quaternary era in which we are now living. Some geologists, however, do not recognize the Quaternary and consider that the Tertiary or Kainozoic extends up to the historic period.

The name was introduced by G. Cuvier and H. Brongniart in 1810 (*Essai sur la géographie minéralogique des Environs de Paris 1810–1811,* 1st ed.) and Deshayes studied the rich assemblages of fossils found in the beds of this age in the Paris Basin. The Tertiary faunas there consist very largely of mollusca of modern aspect and Deshayes (1830) worked out the percentages of recent species found at several horizons. Upon this basis Sir Charles Lyell (1852) founded the main periods, viz., the Eocene



FROM "GEOLOGICAL MAGAZINE" (DUNLAU & CO.)

FIG. 2.—CYCLES OF SEDIMENTATION IN THE HAMPSHIRE BASIN

with $3\frac{1}{2}$ per cent of recent forms, Miocene, 17 per cent, Pliocene 35–50 per cent. Later Beyrich introduced the Oligocene period between the Eocene and Miocene and some geologists distinguish a Palaeocene below the Eocene. Although later studies have shown that it is very doubtful whether *any* existing species are found in the earlier Tertiary periods, the order and nomenclature of the periods have been retained.

It has been found, however, that the Tertiary era falls naturally into two primary divisions so that the grouping now generally adopted is:—

The Newer Tertiary or Neogene	Pliocene Miocene
The Older Tertiary or Palaeogene	Oligocene Eocene Palaeocene

The Palaeogene is characterized by an abundance of nummulites, hence the alternative name "Nummulitic"

Conditions During the Tertiary Era.—Very roughly the Palaeogene and the Neogene periods represent respectively the time before and after the great Tertiary or Alpine earth-movements which resulted in the elevation of most of the major mountain chains of the world, such as the Alps, Himalayas, Rockies and Andes The mountain-building movements commenced in the Eocene and increased in intensity, "the Alpine storm" reaching its height in the Oligocene-Miocene. Thus, whereas the geography of the Older Tertiary period was fundamentally different from that of the present day in that oceanic troughs occupied the emplacements of the great mountains of to-day, the geography of the Newer Tertiary period shows the foundation of the configuration of the present day This aspect is dealt with more fully under the separate articles EOCENE, etc., and is illustrated in the accompanying figures. The end of the Cretaceous was marked in most areas, notably in Europe, by a great regression of the sea The Eocene is characterized by a new marine invasion which proceeded spasmodically and is marked by local regressions, but which generally reached its height in the Lutetian or Middle Eocene. The minor cycles are illustrated in the accompanying diagrams. Then followed a slow and irregular regression in most areas and there is little or no break between the Eocene and Oligocene; elsewhere, especially in northern Germany, the Oligo-

(1) Maximum extension of the Eocene seas. (2) The central European continental area invaded only in Post Eocene (Oligocene) times by arms of the sea on lagoons. (3) Ancient massifs

cene sea invaded areas not previously occupied by the Eocene sea. The end of the Palaeogene is marked by a general regression.

The beginning of the Neogene is marked by the Miocene transgression; then came a new general regression, itself followed by a transgression much less important, that of the Pliocene; finally a last regression which marks the beginning of the Quaternary. It was in the Miocene period that the geography of Europe began definitely to assume its present day form.

Life in the Tertiary.—The faunal aspect of the Tertiary periods differs strikingly from that of the preceding Secondary or Mesozoic; in place of the great reptiles we find the rapid development and finally the maximum expansion of mammals. The Tertiary is often called the Age of Mammals and it is the mammals which furnish the means of distinguishing the subdivisions of the periods and correlating them over wide areas. Snakes and birds advanced rapidly towards their modern position; in the seas bony fish and crab-like decapods increased in number and variety. The ammonites and belemnites so abundant in, and so characteristic of, the Mesozoic periods entirely disappear and give place to lamellibranchs and gastropods of modern aspect—leaving behind such forms as *Rudistes, Inoceramus*, etc. Still more remarkable is the development and abundance in the Early Tertiary period of large foraminifera—the nummulites and orthophragminas. They are excellent zonal fossils if one bears in mind that, for Europe, the "Tethys" or Mediterranean formed their area of evolution and dispersal. In the plant world dicotyledons gradually assumed the leading place which they occupy to-day.

(L. D. S)

TERTULLIAN (*c.* 155–*c.* 222), whose full name was QUINTUS SEPTIMIUS FLORENS TERTULLIANUS, is the earliest and after Augustine the greatest of the ancient church writers of the West. Before him the whole Christian literature in the Latin language consisted of a translation of the Bible, the *Octavius* of Minucius Felix (*q.v.*)—an apologetic treatise written in the Ciceronian style for the higher circles of society, and with no evident effect for the church as a whole, the brief Acts of the Scillitan martyrs, and a list of the books recognized as canonical (the so-called Muratorian fragment). Whether Victor the Roman bishop and Apollonius the Roman senator ever really made an appearance as Latin authors is quite uncertain. Tertullian in fact created Christian Latin literature; one might almost say that that literature sprang from him full-grown, alike in form and substance, as Athena from the head of Zeus. Cyprian polished the language that Tertullian had made, sifted the thoughts he had given out, rounded them off, and turned them into current coin, but he never ceased to be aware of his dependence on Tertullian, whom he designated as κατ' ἐξοχήν, his master (Jer., *De vir ill.* 53).

Life.—Born at Carthage about 150 of good family—his father was a "centurio pro consularis"—he received a first-rate education both in Latin and in Greek. He was able to speak and write Greek, and gives evidence of familiarity alike with its prose and with its poetry; and his excellent memory—though he himself complains about it—enabled him always to bring in at the right place an appropriate, often brilliant, quotation or some historical allusion. The old historians, from Herodotus to Tacitus, were familiar to him, and the accuracy of his historical knowledge is astonishing. He studied with earnest zeal the Greek philosophers; Plato in particular, and the writings of the Stoics he had fully at command, and his treatise *De Anima* shows that he himself was able to investigate and discuss philosophical problems From the philosophers he had been led to the medical writers, whose treatises plainly had a place in his working library. But no portion of this rich store of miscellaneous knowledge has left its characteristic impress on his writings; this influence was reserved for his legal training.

His father, whose military spirit reveals itself in the whole bearing of Tertullian, to whom Christianity was above everything a "militia," had intended him for the law. He studied in Carthage, probably also in Rome, where, according to Eusebius, he enjoyed the reputation of being one of the most eminent jurists. This statement derives confirmation from the *Digest*, where references are made to two works, *De Castrensi Peculio* and *Quaestionum Libri VIII.*, of a Roman jurist named Tertullian, who must have flourished about A.D. 180. In point of fact the quondam advocate never disappeared in the Christian presbyter. This was at once his strength and his weakness: his strength, for as a professional pleader he had learned how to deal with an adversary according to the rules of the art, and was specially qualified to expose the irregularities in the proceedings taken by the state against the Christians; but it was also his weakness, for it was responsible for his litigiousness, his often doubtful shifts and artifices.

At Rome in mature manhood (*c.* 190–195) Tertullian became a Christian, under what circumstances we do not know, and forthwith he bent himself with all his energy to the study of Scripture and of Christian literature. Not only was he master of the contents of the Bible: he also read carefully the works of Hermas, Justin, Tatian, Miltiades, Melito, Irenaeus, Proculus, Clement, as well as many Gnostic treatises, the writings of Marcion in particular. In apologetics his principal master was Justin, and in theology proper and in the controversy with the Gnostics, Irenaeus. As a thinker he was not original, and even as a theologian he has produced but few schemes of doctrine, except his doctrine of sin. His special gift lay in the power to make what had been traditionally received impressive, to give to it its proper form, and to gain for it new currency. From Rome Tertullian visited Greece and perhaps also Asia Minor; at any rate we know that he had temporary relations with the churches there. He was consequently placed in a position in which he could check the doctrine and practice of the Roman church.

Thus equipped with knowledge and experience, he returned to Carthage in 197 and there laid the foundation of Latin Christian literature. At Carthage he became a presbyter, and married. At first, after his conversion, he wrote Greek, but by and by Latin almost exclusively. The elements of this Christian Latin language may be enumerated as follows:—(i.) it had its origin, not in the literary language of Rome as developed by Cicero, but in the language of the people as we find it in Plautus and Terence; (ii.) it has an African complexion; (iii.) it is strongly influenced by Greek, particularly through the Latin translation of the Septuagint and of the New Testament, besides being sprinkled with a large number of Greek words derived from the Scriptures or from the Greek liturgies; (iv.) it bears the stamp of the Gnostic style and contains also some military expressions; (v.) it owes something to the original creative power of Tertullian.

Theology.—As for his theology, its leading factors were:—(i.) the teachings of the apologists; (ii.) the philosophy of the Stoics; (iii.) the rule of faith, interpreted in an anti-Gnostic sense, as he had received it from the Church of Rome; (iv.) the Soteriological theology of Melito and Irenaeus; (v.) the substance of the utterances of the Montanist prophets (which he recognized as a work of God in 202–3). This analysis does not disclose, nor indeed is it possible to discover, what was the determining element for Tertullian; in fact he was under the dominion of more than one ruling principle, and he felt himself bound by several mutually opposing authorities. It was his desire to unite the enthusiasm of primitive Christianity with intelligent thought, the original demands of the Gospel with every letter of the Scriptures and with the practice of the Roman church, the sayings of the Paraclete with the authority of the bishops, the law of the churches with the freedom of the inspired, the rigid discipline of the Montanist with all the utterances of the New Testament and with the arrangements of a church seeking to set itself up within the world.

At this task he toiled for years, involved in contradictions which taxed all the finished skill of the jurist to conceal from him for a time. His efforts to secure the triumph of Montanism within the Church involved him in bitter controversy with the clergy at Carthage, who had the support of Rome. At last (*c.* 207–08) he felt compelled to break off from the church for which he had lived and fought and he became the head of the small Montanist community in Carthage; but the breach could not clear him from the contradictions in which he found himself entangled. Not only did the great chasm between the old Christianity, to which his soul clung, and the Christianity of the Scriptures as juristically and philosophically interpreted remain unbridged; he also clung fast, in spite of his separation from the Catholic church, to his position that the church possesses the true doctrine, that the bishops *per successionem* are the repositories of the grace of the teaching office, and so forth. The growing violence of his latest works is to be accounted for, not only by his burning indignation against the ever-advancing secularization of the Catholic church, but also by the incompatibility between the authorities which he recognized and yet was not able to reconcile. After having done battle with heathens, Jews, Marcionites, Gnostics, Monarchians, and the Catholics, he died at a great age.

What has just been said brings out very clearly how important in their bearing on Tertullian's development were the circumstances of the age in which he laboured. His activity as a Christian falls between 190 and 220, a period of very great moment in the history of the Catholic church; for within it the struggle with Gnosticism was brought to a victorious close, the New Testament established a firm footing within the churches, the "apostolic" rules which thenceforward regulated all the affairs of the church were called into existence, and the ecclesiastical priesthood came to be developed. Within this period also falls that evangelical and legal reaction against the political and secular tendencies of the church which is known as Montanism. The same Tertullian who had fortified the Catholic church against Gnosticism was none the less anxious to protect it from becoming a political organization. Being unable to reconcile incompatibles, he broke with the church and became the most powerful representative of Montanism in the West.

Works.—The works of Tertullian, on the chronology of which a great deal has been written, and which for the most part do not admit of being dated with perfect certainty, fall into three classes —the apologetic, defending Christianity against paganism and Judaism; the polemical dogmatic, refuting heresies and heretics; and the ascetic or practical, dealing with points of morality and church discipline. In point of time also three periods can be readily distinguished (*see* below).

I. *Works dating from before 202–203.*—To this class belong the *Apologeticus* (197) and the two books *Ad nationes, De spectaculis, De idololatria, De cultu feminarum Libri II., De testimonio animae* (written soon after the *Apologeticus*), *Ad martyres* (perhaps the earliest of all), *De baptismo haereticorum* (now lost), *De baptismo, De poenitentia, De oratione* (the last three written for catechumens), *De patientia, Ad uxorem Libri II., De praescriptione haereticorum,* and *Adv. Marcionem* (in its first form).

II. *Works written between 202–203 and 207–208.*—*De virginibus velandis, De corona militis, De fuga in persecutione, De exhortatione castitatis, De scorpiace* (a booklet against the Gnostics, whom he compares to scorpions; it is written in praise of martyrdom), *Adversus Hermogenem, De censu animae adv. Hermogenem* (lost), *Adv. Valentinianos, Adv. Apelleiacos* (lost), *De paradiso* (lost), *De fato* (lost), *De anima* (the first book on Christian psychology), *De carne Christi, De resurrectione carnis,* and *De spe fidelium* (lost), were all written after Tertullian had recognized the prophetic claims of the Montanists, but before he had left the church.

III. *Works later than 207–208.*—To this period belong the five books *Adv. Marcionem,* his main anti-Gnostic work (in the third form—the first of the five was written in 207–208), *Ad Scapulam* (an admonition to the persecuting proconsul of Africa, written soon after 212), *De pallio* (a defence of his wearing the pallium instead of the toga), *Adv. Praxean* (his principal work against the Monarchians), and *Adv. Judaeos,* chaps. ix.–xiv. of which are a completion by another and less skilful hand. The latest extant works of Tertullian (all after 217) are his controversial writings against the laxity of the Catholics, full of the bitterest attacks, especially upon Calixtus, the bishop of Rome; these are *De monogamia, De jejunio, De pudicitia,* and *De ecstasi Libri VII.* (lost). It is quite possible that Tertullian was the author of the *Acta perpetuae et felicitatis,* but he did not write the *Libellus adv. omnes haereses* often appended to *De praescriptione;* or the poems *Adv. Marcionem, De Sodoma, De Jona, De Genesi, De judicio Domini;* or the fragment *De execrandis gentium diis;* or the *De Trinitate* and *De cibis Judaicis* of Novatian.

Editions.—For the MSS. *see* E. Preuschen in A. Harnack, *Geschichte der altchristl. Literatur,* i. 675–7. Of printed collections the chief are the *editio princeps* by Beatus Rhenanus (Basel, 1521), Migne, *Patr. Lat.* i.–ii. (Paris, 1844); Fr. Oehler (3 vols., Leipzig, 1851–4); A. Reifferscheid and G. Wissowa in the *Corpus scriptorum eccl. Lat.* (Pars i., Vienna, 1890), Oehler's text of the *Apologeticus* with trans. into English by A. Souter and notes by J. E. B. Mayor (1917). Editions of the separate books are almost innumerable.

Translations.—German by K. A. H. Kellner (2 vols. Cologne, 1882) and selections in *Bibliothek der Kirchenväter* (1869, 1872); English by S. Thelwall and others in *Ante-Nicene Fathers,* iii. and iv., and (apologetic and practical writings) by C. Dodgson in *Library of the Fathers,* x. (Oxford, 1842); and translations by A. Souter of the treatises on prayer and baptism (1919).

Literature.—Fr. Oehler's third volume contains a collection of early dissertations. *See* also A. Hauck, *Tertullian's Leben und Schriften* (Erlangen, 1877); J. M. Fuller in *Dict. Chr. Biog.,* iv. 818–864; E. Nolldechen, *Tertullian* (Gotha, 1890); P. Monceaux, *Histoire littéraire de l'Afrique chrétienne,* vol. i. (Paris, 1901); T. R. Glover, *The Conflict of Religions in the Early Roman Empire,* chap. x. (Lon-

don, 1909); and the various Histories of Dogma and Church Histories.

For a complete bibliography *see* G. Krüger, *Hist. of Early Christian Literature* (Eng. tr. New York and London, 1897); Herzog-Hauck, *Realencyk. fur prot. Theologie*, xix; and O. Bardenhewer, *Patrology* (Eng. tr. Freiburg im Breisgau and St. Louis, 1908).

TERUEL, a province of north-eastern Spain, formed in 1833 from part of the ancient kingdom of Aragon; bounded on the north by Saragossa, east by Tarragona, south-east and south by Castellon de la Plana and Valencia, south-west by Cuenca, and west by Guadalajara. Pop. (1920) 252,096; area 5,720 sq m. In the centre of the province rise the Sierras of Gudar and San Just; in the south-west and west are the lofty Albarracin range, the Montes Universales, and the isolated ridges of Palomera and Cucalon. Outliers of the Castellon and Tarragona highlands extend along the eastern border. The northern districts belong to the Ebro basin. In the west there are a few peaks, such as the Cerro de San Felipe and Muela de San Juan, which exceed 5,000 ft. in altitude and are covered with snow for many months; but the highest point is Javalambre (6,568 ft) in the south. The sierras give rise to several large rivers, the principal being the Tagus (*q.v.*); the Guadalaviar, which rises in the Montes Universales and enters the Mediterranean at Valencia; and the Jiloca, which flows north from the lake of Cella to join the Jalón at Calatayud. The chief products are corn, wine, oil, cheese, fruits, timber, flax, hemp, silk, wool and saffron, together with cattle, sheep and swine. The only railway is the line from Murviedro, on the Gulf of Valencia, to Calatayud. Teruel (*q v.*) and Alcañiz (8,648) are the only towns

TERUEL, the capital of the Spanish province of Teruel; on the left bank of the river Guadalaviar, at its confluence with the Alfambra, and on the Murviedro-Calatayud railway Pop (1920) 12,010. The older part of Teruel is a walled city with narrow streets and crumbling mediaeval houses, but modern suburbs have been built outside the walls. In the cloisters of San Pedro lie the remains of the celebrated "lovers of Teruel," Juan de Marcilla and Isabella de Segura (13th century). Their story is the subject of works by Tirso de Molina, Artieda, Montalban, Hartzenbusch and others. The cathedral dates from the 16th century. The great aqueduct was erected in 1555–60 by Pierre Bedel, a French architect. The see was created in 1577.

TERZA RIMA, or "third rhyme," a form of verse developed by the Italian poets of the 13th century. Its origin has been attributed by some to the three-lined ritournel, which was an early Italian form of popular poetry, and by others to the *Provençals serventese incatenato*, an arrangement of triple rhymes, which unquestionably appears to have a relation with terza rima; Dante gave to terza rima its artistic character. What this character is may best be seen by an examination of the lines with which the *Inferno* opens.

Nel mezzo del cammin di nostra vita
Mi ritrovai per una selva oscura,
Ché la diritta via era smarrita.
Ah quanto a dir qual 'era è cosa dura
Questa selva selvaggia ed aspra e forte,
Che nel pensier rinnova la paura!

It is impossible, however, to break off here, since there is no rhyme to *forte*, which has to be supplied twice in the succeeding terzina, where, however, a fresh rhyme, *trovai*, is introduced, linking the whole to a still further terzina, and so on, indefinitely in the sequence *aba, bcb, cdc, ded* . . . Boccaccio wrote terza rima in close following of Dante, but it has not been a form very frequently adopted by Italian poets. The difficulty of sustaining dignity and force in these complicated chains of verse has usually deterred writers in other languages from adventuring on terza rima. In the age of Elizabeth, Samuel Daniel employed it in his "Epistle to the Countess of Bedford," but he found no followers. Shelley tried it in two poems (*Prince Athanase* and *The Triumph of Life*), Byron in one (*The Prophecy of Dante*), but probably the most successfully sustained poem in terza rima in the English language is Mrs. Browning's *Casa Guidi Windows* (1851).

TESCHEN, a town and district of Poland and Czechoslovakia. Teschen (Czech *Těšin*, Polish, *Cieszyn*), lies in the south-east corner of Silesia, and was a duchy disputed between the kings of Poland and Bohemia from the 9th century onward. In the 17th century it came under Habsburg rule. It is 852·6 sq.m. in extent. It is rich both in coke and gas coal, and is an important strategic centre of roads and railways, especially of the Bohumin (Oderberg) line. Its population in 1921 was 144,671, of whom 76·5% were Poles, 20% Germans, 3% Jews and ·3% Czechs. Both Czechs and Poles desired to succeed Austria in the possession of Teschen; in May–June 1918, their representatives decided to settle the matter in friendly agreement. When, however, Poland elected deputies from Teschen for her constituent parliament, Czech troops advanced and occupied Oderberg in Jan. 1919. The Great Powers intervened and decided (Sept. 27, 1919) to hold a plebiscite under the auspices of the principal Allies, not only for the duchy of Teschen but also for the adjacent Suvan areas of Spiš (Zips) and Orava. This commission did not arrive until Jan. 1920, when they were confronted with riots, strikes and other difficulties. They appealed to the Conference of Ambassadors at Paris, which, on July 28, 1920, abandoned the plebiscite plan and induced both Czechs and Poles to agree to a partition. The Spiš-Orava areas offered few difficulties. In the duchy itself the Czechs obtained the Karvinna (Karwin) mining area and the Oderberg-Jablunkov railway, the Poles the town of Teschen, except its western suburb, and an agricultural area. The economic unity of the duchy was preserved by an arrangement which afterwards served as a model for the partition of Upper Silesia.

See H. W. V. Temperley, *History of the Peace Conference of Paris*, vol. iv. (chap. vi., pt. 1 [1921] by R. Fitzgibbon Young).

TESLA, NIKOLA (1857–), American inventor, was born at Smiljan, Austrian Croatia. He graduated from the *realschule*, Karlstadt, in 1873, and studied at the polytechnic school, Graz, Croatia, and the University of Prague, intending to specialize in physics and mathematics, but became interested in electricity. He was first employed in the Austrian Government telegraph engineering department, later being engaged in electrical engineering in Budapest and Paris He went to the United States in 1884. For a time he was with the Edison Co. at Orange, N J, but relinquished his position in order to devote himself to research, for which purpose he established the Tesla laboratory in New York city. He was the first to conceive an effective method of utilizing the alternating current and in 1888 patented the induction motor, by means of which electrical energy might be converted into mechanical energy more effectively and economically than by the direct current. He invented the principle of the rotary magnetic field embodied in the apparatus used in the transmission of power from Niagara falls. He also invented new forms of dynamos, transformers, induction coils, condensers, arc and incandescent lamps and other electrical apparatus.

TEST ACTS. The principle that none but persons professing the established religion were eligible for public employment was adopted by the legislatures of both England and Scotland soon after the Reformation. In England the acts of Supremacy and Uniformity and the severe penalties pronounced against recusants, whether Roman Catholic or Nonconformist, were affirmations of this principle. The act of 7 Jac.I c.2 provided that all such as were naturalized or restored in blood should receive the sacrament of the Lord's Supper, and under Charles II. the actual receiving of the communion of the Church of England was made a condition precedent to the holding of public offices. The earliest imposition of this test was by the Corporation act of 1661 (13 Car. II st. 2, c.1), enacting that, besides taking the oath of allegiance and supremacy and subscribing a declaration against the Solemn League and Covenant, all members of corporations were within one year after election to receive the sacrament of the Lord's Supper according to the rites of the Church of England. This act was followed by the Test act of 1672 (25 Car. II. c.2), the immediate consequence of the king's declaration of indulgence, dispensing with laws inflicting disabilities on Nonconformists. This act enforced upon all persons filling any office, civil or military, the obligation of taking the oaths of supremacy and allegiance and subscribing a declaration against transubstantiation, and also of receiving the sacrament within three months after admittance to office. The act did not extend to peers; but in 1678 (30 Car. II. st. 2) enacted that all peers and members of the House of Commons

should make a declaration against transubstantiation, invocation of saints, and the sacrifice of the mass—an exception being made in favour of the Duke of York. The provisions of the Test act were violated by both Charles II. and James II. on the ground of the dispensing power claimed by the Stuart kings. In the case of *Godden* v. *Hales* (11 State Trials, 1,166), an action for penalties under the Test act brought against an officer in the army, the judges decided in favour of the dispensing power—a power finally abolished by the Bill of Rights. After a considerable number of amendments and partial repeals of these acts, and of acts of indemnity to protect persons from penalties incurred under the Test act, the necessity of receiving the sacrament as a qualification for office was abolished by 9 Geo. IV. c. 17, and all acts requiring the taking of oaths and declarations against transubstantiation, etc., were repealed by the Roman Catholic Relief act of 1829 (10 Geo. IV. c.7). This general repeal was followed by the special repeal of the Corporation act by the Promissory Oaths act 1871, of the Test act by the Statute Law Revision act 1863, and of the act of 1678 by an act of 1866 (29 & 30 Vict. c.19). In 1871 the University Tests act abolished subscriptions to the articles of the Church of England, all declarations and oaths respecting religious belief, and all compulsory attendance at public worship in the universities of Oxford, Cambridge, and Durham. There is an exception restricting to persons in holy orders of the Church of England degrees in divinity and positions such as the divinity and Hebrew professorships.

In Scotland a religious test was imposed immediately after the Reformation. By 1567, c.9 no one was to be appointed to a public office or to be a notary who did not profess the Reformed religion. The Scottish Test act (1681, c.6) was rescinded by 1690, c.7. By 1700, c.3, renunciation of popery was to be made by persons employed in education. By 1707, c.6, all professors, principals, regents, masters, or others bearing office in any university, college, or school in Scotland were bound to profess and subscribe to the Confession of Faith; and all persons were to be free of any oath or test contrary to or inconsistent with the Protestant religion and Presbyterian Church government. The necessity for subscription to the Confession of Faith was removed for persons other than principals and professors of theology by 16 and 17 Vict. c.89. The act provided that in place of subscription every person appointed to a university office was to subscribe a declaration according to the form in the act, promising not to teach any opinions opposed to the divine authority of Scripture or to the Confession of Faith, and to do nothing to the prejudice of the Church of Scotland or its doctrines and privileges. All tests were finally abolished by an act of 1889 (52 & 53 Vict. c.55). The reception of the communion was never a part of the test in Scotland as in England and Ireland.

In Ireland an oath of allegiance was required by the Irish act of Supremacy (2 Eliz. c.1). The English act of 3 Will. & M. c.2 substituted other oaths and enforced in addition from peers, members of the House of Commons, bishops, barristers, attorneys, and others a declaration against transubstantiation, invocation of the Virgin Mary and the saints, and the sacrifice of the mass. By the Irish act of 2 Anne, c.6, every person admitted to any office, civil or military, was to take and subscribe the oaths of allegiance, supremacy, and abjuration, to subscribe the declaration against transubstantiation, etc., and to receive the Lord's Supper according to the usage of the Church of Ireland. English legislation on the subject of oaths and declarations was adopted in Ireland by Yelverton's act, 21 & 22 Geo. III. c.48, § 3 (Ir.). These provisions were all repealed by the Promissory Oaths act 1871. The Roman Catholic Relief act of 1793 (33 Geo. III. c.21. Ir.) excepted Trinity College, Dublin, from its provisions, and tests existed in Dublin university—except for professors and lecturers in divinity—until finally abolished by the University of Dublin Tests act 1873.

In the United States by art. 6 of the constitution, "no religious test shall ever be required as a qualification to any office or public trust under the United States." A similar provision is generally included in the state constitutions.

TESTAMENTS OF THE TWELVE PATRIARCHS.

The Testaments of the Twelve Patriarchs are an important constituent of the apocryphal scriptures connected with the Old Testament, comprising the dying commands of the twelve sons of Jacob.

They were written in Hebrew in the later years of John Hyrcanus—in all probability after his final victory over the Syrian power and before his breach with the Pharisees—in other words, between 109 and 106. Their author was a Pharisee who combined loyalty to the best traditions of his party with the most unbounded admiration of Hyrcanus. The Maccabean dynasty had now reached the zenith of its prosperity, and in its reigning representative, who alone in the history of Judaism possessed the triple offices of prophet, priest and king, the Pharisaic party had come to recognize the actual Messiah. When we contrast the expectations of the original writer and the actual events that followed, it would seem that the chief value of his work would consist in the light that it throws on this obscure and temporary revolution in the Messianic expectations of Judaism towards the close of the 2nd century. But this is not so. The main, the overwhelming value of the book lies not in this province, but in its ethical teaching, which has achieved a real immortality by influencing the thought and diction of the writers of the New Testament, and even those of our Lord. This ethical teaching, which is indefinitely higher and purer than that of the Old Testament, is yet its true spiritual child, and helps to bridge the chasm that divides the ethics of the Old and New Testaments.

Date.—The indications in the book itself make it quite clear that it was written (1) in Hebrew, and (2) between 109–107 B.C. There are, however, numerous additions. A large body of these additions can be classed under one head as written with a well-defined object and at a definite period. This period was about 70–40 B.C., and the object of the additions was the overthrow of the Maccabean high-priesthood, which in the 1st century B.C. had become guilty of every lewdness. Test. Lev. x., xiv.–xvi.; Test. Jud. xvii. 2–xviii. 1 (?), xxi. 6–xxiii., xxiv. 4–6; Test. Zeb. ix.; Test. Dan. v. 6–7, vii., 3 (?); Test. Naph. iv.; Test. Gad. viii. 2; Test. Ash. vii. 4–7. These additions are identical in object and closely related in character and diction with the Psalms of Solomon. Other additions are of various dates and cannot be more than mentioned here; *i.e.*, Test. Reub. ii. 3–iii. 2; Test. Lev. xvii. 1–9; Test. Zeb. vi. 4–6, vii.–viii. 3; Test. Jos. x. 5–xviii.

Christian Additions to the Text.—These additions are to be found in most of the Testaments and were made at different periods. The existence of these Christian elements in the text misled nearly every scholar for the past 400 years into believing that the book itself was a Christian apocryph. To Grabe, Schnapp and Conybeare belongs the credit of showing that the Christian elements were interpolations—to Conybeare especially of the three, since, whereas the two others showed the high probability of their contention on internal evidence, Conybeare proved by means of the Armenian version that when it was made many of the interpolations had not yet found their way into the text. For a full treatment of these passages *see* Charles's *Testaments of the Twelve Patriarchs* (1908), Introd. §20.

Influence on the New Testament.—St. Paul twice quoted from the Greek text of the Testaments: Rom. i. 32 and 1 Thess. ii. 16. But these give the very faintest idea of the degree of his indebtedness in thought and phraseology in several of his Epistles, especially that to the Romans. Of still greater interest are the passages in the Gospels which show the influence of the Testaments, and these belong mainly to the sayings and discourses of our Lord. We may mention two of the most notable of these. Thus Matt. xviii. 15, 35, which deal with the great question of forgiveness, are clearly dependent on our text.

Matt. xviii. 15.	T. Gad. vi. 3.
'Εὰν δὲ ἁμαρτήσῃ ὁ ἀδελφός σου κατά σου, ὕπαγε ἔλεγξον αὐτὸν μεταξὺ σοῦ καὶ αὐτοῦ μόνου.	*'Εὰν τις ἁμαρτήσει εἰς σὲ εἰπὲ αὐτῷ ἐν εἰρήνῃ . . . . καὶ ἐὰν . . . . μετανοήσῃ, ἄφες αὐτῷ* vi. 6 *ἡσύχασον μὴ ἐλέγξῃς.*
35. *'Εὰν μὴ ἀφῆτε ἕκαστος τῷ ἀδελφῷ αὐτοῦ ἀπὸ τῶν καρδιῶν ὑμῶν.*	v. 7 *"Αφες αὐτῷ ἀπὸ καρδίας*

Next, the duty of loving God and our neighbour is already found in Test. Dan. v. 3, which is the oldest literary authority which en-

joins these two great commands The form is infinitely finer in Matt. xxii. 37–39, but the matter is already in the Test. Dan. *See* Introd. §26 to R. H. Charles's *Testaments of the Twelve Patriarchs.*

Besides Charles (as above), are his *Apoc. and Pseudepig.* vol. ii. and the S.P.C.K. *Translations of Early Documents* (1917). (R. H. Ch.)

TESTAMENTUM DOMINI ("Testament of Our Lord"), one of that series of writings, claiming to embody the fundamental rules of the early church, which culminates in the "Apostolic Constitutions" (*q.v.*). Extracts from the book which bears this title, contained in an 8th-century MS at Paris, were published by Lagarde in 1856, and a Latin fragment, edited by Dr. Montague James, appeared in 1893 (*Texts and Studies,* i. 154). The whole book was first published in Syriac in 1899, with a Latin translation by Mgr Rahmani, the Uniat Syrian Patriarch of Antioch. His text is that of a 17th-century MS. at Mosul, translated from the original Greek by James of Edessa, in A D. 687; but he makes use of other material, including an Arabic version made from a Coptic copy written in A D. 927. The Mosul MS. contains the whole Bible in the Peshitto version, followed by the collection of ecclesiastical law, in eight books, which was used by the Nestorians and Jacobites. Of this the *Testament* forms the first two books; and according to the title (which, apparently by an error, is made to apply to the whole eight books) it contains the "testament, or words which Our Lord spake to His holy Apostles when He rose from the dead."

The Testament has several distinctive characteristics. First and foremost is its ascription to the Lord Himself, which scholars can hardly be mistaken in regarding as an attempt to claim a yet higher sanction than was claimed by the various compilations styled "apostolic." This fact alone would lead us to infer the pre-existence of certain of the latter. Again, the whole tone of the *Testamentum* is one of highly strung asceticism, and the regulations are such as point by their severity to a small and strictly organized body. They are "the wise," "the perfect," "sons of light"; but this somewhat Gnostic phraseology is not accompanied with any signs of Gnostic doctrine, and the work as a whole is orthodox in tone. They are set in the midst of "wolves," despised and slighted by the careless and worldly: there is frequent mention of "the persecuted," and of the duty of "bearing the cross." There appears to be no *locus poenitentiae* for serious sins excepting in the case of catechumens, and there is a notable "perfectionist" tone in many of the prayers. *Charismata,* and above all exorcisms, occupy a very important place: there is a vivid realization of the ministry of angels, and the angelic hierarchy is very complete. Great stress is laid upon virginity (although there is not a sign of monasticism), upon fasting (especially for the bishop), upon the regular attendance of the whole clerical body and the "more perfect" of the laity at the hours of prayer.

Amongst the festivals mentioned are the Epiphany, Easter and Pentecost. With regard to the prayers, they are based upon forms common to this and other Church orders, but have many lengthy interpolations of an inflated and rhapsodic kind. The bishop appears to rank far above the presbyters (more conspicuously so, for example, than in the Canons of Hippolytus), and the presbyters are still divided into two classes, those who are more learned and those who are of mature age. The deacons have functions in the Eucharist and about the altar which point to an early date; they have also much administrative work of an important kind, and especial provisions are made for the care of the sick and the dead, and the burial of those who perish by shipwreck. One of the deacons is to be chosen as "chief deacon" (*protodiaconus,* i 19 *cf.* i. 34), and is charged with the care of pilgrims. There are no doorkeepers or singers, who begin to appear *circ.* A D. 340 The honour given to confessors is very conspicuous, and points back to an early date. But remarkable above all is the position given to women. We have "widows having precedence" or presbyteresses, three in number. deaconesses, virgins, and widows who are in receipt of the alms of the Church; and the first-named occupy a place of very great dignity, which is almost unequalled elsewhere, and which was formally condemned by the Council of Laodicea in Phrygia

What conclusion is to be drawn, then, as to the age and character of the *Testament?* Mgr. Rahmani's view, that it is a work of the 2nd century, is universally discredited; nor has Funk's contention found acceptance, that it and the Canons of Hippolytus are alike derived ultimately from the eighth book of the *Apostolic Constitutions.* Some scholars think that the Apocalypse at the beginning is pre-Nicene (A D 250–325), and that it originates from Asia Minor, probably from Montanistic circles. But the unity of thought and atmosphere is such as to show that the work is one whole (subject no doubt to a certain amount of redaction and interpolation), and that the apocalyptic part was composed as an introduction to the rest As to the central portion (i. 19–ii. 24) it is a Church Order of the same kind as the Canons of Hippolytus (*c.* 220) and the Egyptian (*c.* 310) and Ethiopic (*c.* 335) Church Orders, standing nearer to the two latter than to the former.

Such redaction was indeed inevitable in the case of a work which has had a living history as part of a codex of Church law. It may be discerned in the interpolations in the prayers; possibly in the reference to the chief deacon, for elsewhere no single deacon is distinguished *by name* until the close of the 4th century; in the reference to the Epiphany, which is first heard of elsewhere at the beginning of the 4th century.

TESTER, a canopy (*q.v.*) over a bed or altar.

TESTING MACHINERY: *see* Materials, Strength of.

TEST PIT. A test pit may be used for many purposes, but in its generally accepted meaning the term refers to a heavily lined pit sunk in the floor of an industrial factory building, and employed in making strength and balancing tests on the revolving parts of such machines as large electric generators, motors, and steam and hydraulic turbines.

The necessity for such pits arises from the fact that machines are usually tested at speeds considerably in excess of those at which they will normally run, and consequently there is the risk of disruption, with the likelihood of great damage to property and loss of life if proper protection is not provided While it is not intended that such tests shall be carried to the point of destruction, a certain factor of safety must be present in the machines, and this can only be demonstrated by actual over-speed tests.

Test pits are therefore sunk beneath the shop floor level, and are heavily lined with reinforced concrete and steel. All up-to-date manufacturers of large revolving machines are equipped to make such tests with safety to their employees and equipment. There are cases on record of very serious accidents resulting from the disruption of rapidly revolving machines improperly protected, and the modern tendency is toward more heavily armoured pits located in isolated sections of the manufacturing plants

The largest test pit in the world is that designed and built by the General Electric Company in 1927, at their principal plant which is situated at Schenectady, N.Y. This pit is located in a special building with other testing equipment, a quarter of a mile from the nearest factory building. It is 30ft. deep and 45ft. in inside diameter, and is capable of enclosing the rotating member of the largest electrical machine likely to be built for many years. The walls are of double concrete construction with a layer of soft sand in between, and with a total thickness of 14ft. The floor is a concrete slab faced with steel, and is supported by wooden piles driven 60ft. into the ground. The entire construction is reinforced with one-inch steel bars cast in the concrete, giving even greater rigidity than is necessary in the case of large dams and bridges.

The top of the pit is closed by a removable lid made of steel plates and girders, and is held in place by eight steel wedges each

a yard long. For testing purposes the rotating machine is lowered into the pit by a travelling crane, and is supported in a huge roller bearing at the bottom, capable of carrying a load of 500 tons. The shaft of the machine is held in the vertical position by a small upper bearing, and is connected by a coupling to an electric motor installed upon the top of the lid. Motors of as high as 3,000 h.p. are used to revolve the largest rotors at test speeds.

The pit may be used for any tests where bomb-proof protection is required. Its principal use, however, is in performing "double speed" tests on large hydro-electric generator rotors. The object of such tests is to establish the fact that rotors will not fly apart even under the maximum "runaway" conditions which might exist during an emergency in service. Huge centrifugal forces and enormous rim velocities are developed in these tests, the rim speed of the largest machine (1928) being of the order of 20,000ft. per min. (about 227m. per hour).

During the test runs no one is allowed to remain in the pit building. The observers retire to a control house 100 yards away and there manipulate the speed of the electric motor driving the machine under test, by means of a switchboard connected with the pit through underground cables. Indicating meters record the speed and degree of vibration, and telephonic communication with a microphone in the pit transmits to the observers the sounds made by the machine as it revolves. By these means it is expected that sufficient warning of a breakdown will be given, so that the test can be stopped before the machine or pit is damaged. (D. O. W.)

TESTUDO, "tortoise," the name of two military devices used by the Romans in attacking a fortified place. (1) A wooden frame covered with clay or hides as a protection against fire. Under its protection the battering ram (*aries*) was advanced to the foot of the city wall and operated in safety. (2) A device of locking together the legionaries' shields above their heads, to form a sort of shell, under which they advanced to the attack. A good representation of this is to be seen on the column of Marcus Aurelius.

TETANUS or **LOCKJAW,** a disease caused by the toxin of *Bacillus tetani* (*see* BACTERIA AND DISEASE), an anaerobic bacillus found in soil contaminated by horse dung and therefore in the dust of streets and of gardens and other cultivated land. The bacilli or their spores gain access to the body through a breach of the surface, perhaps trivial, and remain localized. The toxin they elaborate travels by the sheaths of local nerves upwards affecting the nerves themselves in its course towards the spinal cord. Ultimately nerve cells are affected. The necessary conditions for multiplication of the bacilli locally are afforded by the dirt and other micro-organisms gaining access to the wound with the tetanus bacilli. Tetanus may affect persons at any age, even the newly born infant, but is commonest in male adults; in hot countries it is more common, largely because the natives go barefoot. Horses are very liable to the disease.

In man the first symptom is stiffness in the back of the neck or the muscles of the jaw and face. There is difficulty in opening the mouth and the corners of the mouth are drawn downwards and backwards and fixed in that position (*risus sardonicus*). The jaw is so firmly set that it is impossible to pass anything between the teeth. Soon difficulty in swallowing comes on because the muscles of the throat are involved and the abdominal muscles are rigidly fixed. The muscles of the limbs are attacked by agonizing cramps, and, last of all, the muscles of the chest are involved. Though all the muscles are in a continuous state of contraction, thereby differing from strychnine poisoning which tetanus otherwise resembles, the spasmodic contractions come on in addition, and occasionally are so severe that the patient is doubled up forwards, backwards or sideways and perhaps some of the muscles tear across. These spasms may be induced by very slight causes, a sudden small noise, a breath of wind, shaking of the bed.

The sooner the symptoms come on after the injury the worse is the prognosis of tetanus. In the absence of antitoxin treatment when they arise within a week of the injury the prospect of recovery is extremely remote; if within ten days the prospects are bad; if they do not come on until three weeks or so after the injury there is hope. As shown below the prognosis is much improved by prophylactic antitoxin treatment. In the developed disease antitoxic serum is of doubtful value even though injected intrathecally by lumbar puncture. The only available treatment is absolute quiet in a darkened room, morphia to relieve pain, and such amount of liquid food as will sustain life.

Preventive Treatment.—On the appearance of tetanus in the British army during the early days of the World War immediate steps were taken to cope with it. The disease could be prevented if a dose of anti-tetanus serum were given as soon as a wound was sustained because some days elapse before the bacilli, which remain in the wound, are able to secrete sufficient poison to precipitate an attack. From that time every wound, no matter how slight, was followed as soon as possible by a dose of anti-tetanic serum. Out of 1,242,000 wounded men who were sent home to England, 1,458 cases of tetanus arose, giving a ratio of rather more than 1 per 1,000. In Sept. 1914 the ratio of tetanus cases to wounds was 9 per 1,000. In Oct. 1918 the ratio was 0·5.

In Nov. 1914 preventive inoculation, introduced about the middle of Oct. 1914, had begun to exercise its beneficial effects. The following figures giving the number of cases of tetanus per 1,000 wounded men make this clear:

	Cases of tetanus		Cases of tetanus
Sept. 1914	9·0	Feb. 1915	1·1
Oct 1914	7·3	March 1915	0·4
Nov 1914	2·3	April 1915	2·3
Dec. 1914	1·4	May 1915	0·8
Jan. 1915	0·0	June 1915	0·2

The same experience was met with in the French and German armies. As soon as preventive inoculation with anti-tetanic serum became a universal practice, the incidence of tetanus dropped sharply and remained small. In June 1917 it was ordered that each wounded man should receive not one inoculation as formerly but four, at intervals of a week, because the minimizing effect of the serum passes away rather quickly.

The medical department of the United States army required that a prophylactic dose of 1,000 units of tetanus antitoxin be given to all wounded, whatever the nature or severity of the wound, as soon as possible after the infliction of the wound. In such cases, at least one subsequent dose of 1,000 units was to be given after an interval of seven days. Tetanus antitoxin was also to be administered as a routine measure in the following conditions: (1) Upon the recognition of "trench foot," with or without skin abrasions. (2) In case of frost bite. (3) During operations performed under conditions of unsatisfactory asepsis. (4) During secondary operations necessary in the course of treatment of wounds received seven or more days previously. (5) Following the manipulations incident to the reduction of compound fractures or dislocations, after the removal of adherent drains, or any other procedure resulting in the disturbance of the healing process in a wound seven or more days old. As a resultant of these means, the incidence of tetanus in the United States army during the World War was decidedly low; so low, indeed, that only 36 cases were reported as being associated with 176,132 battle injuries. There were but 23 primary admissions to hospital because of tetanus.

The effect is not always to prevent absolutely. But even in those cases in which tetanus does supervene in spite of the inoculations, the incubation period is lengthened and the death rate is lowered; other things being equal, a long incubation period tends to result in a milder attack than a short incubation period, thus any circumstance prolonging the incubation period will also tend to lower the death rate. Only 26·9% of the inoculated are attacked during the first fortnight, whereas 68·9% of the uninoculated are attacked. Among the protected 40·0% have an incubation period of more than 35 days; among the unprotected only 6·5%. The average incubation among inoculated is 45·5 days, among uninoculated 10·9 days. Indeed, in each year of the war the incubation period tended to rise. Further, the inoculations tended to limit the degree of tetanus, converting what would be generalized cases into local or one-limb cases. The following table illustrates this:

Tetanus type	Percentages				
	1914	1915	1916	1917	1918
General	98·9	98·6	87·0	76·6	83·5
Local	1·1	1 4	13·0	23·4	16 5

Local tetanus tends to occur in the wounded or injured limb and to be confined to that limb. It is much less severe and far less fatal than the generalized type. Naturally the death rate reflected these successes. Among the unprotected and unrecorded the death rate was 53·5% Among the protected it was 23·0%. The "unrecorded" here undoubtedly include cases which had received a dose. The method employed during the war fully justified the hopes which were entertained concerning it.

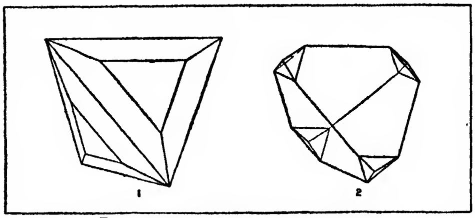
TETRADYMITE, a mineral consisting of bismuth telluride and sulphide, Bi_2Te_2S, also known as "telluric bismuth." Sometimes sulphur is absent and the formula is then Bi_2Te_3; traces of selenium are usually present. Crystals are rhombohedral, but are rarely distinctly developed; they are twinned together in groups of four; hence the name of the mineral, from the Greek, τετραδυμος, fourfold. There is a perfect cleavage parallel to the basal plane; and the mineral usually occurs in foliated masses of irregular outline. The colour is steel-grey, and the lustre metallic and brilliant. The mineral is very soft (H.=1·5) and marks paper; the specific gravity is 7·2 to 7·6. It often occurs in quartz associated with native gold. (L J. S)

TETRAGRAMMATON, the Hebrew four-lettered name of God, commonly known as Jehovah through a misapplication of the vowels belonging to *Adonai* (Lord) to the letters J H V H. Possibly the causative (*hiph'il*) imperfect reading, i.e, *Yahwèh* (He who causes to be or to fall) is the correct form. As early as the time of the Chronicler *Adonai* was substituted for the divine name: evidence for this change is supplied also by the LXX. Origen (Ps. ii.) mentions that the best Bible codices kept the Hebrew name of God in the archaic characters. The recently discovered fragments of Aquila's translation observe this rule and use יהוה (*see* examples in H. B. Swete's *Introd. to O.T. in Greek*, p. 38, 1902; *see* also F. C. Burkitt, p. xii. of *Legacy of Israel*, 1927) which was easily mistaken for Greek uncials IIIII and so this absurd form arose; it is still perpetuated on the Masonic tracing boards where IIIII figures on the cloud between the pillars Jachin and Boaz. The real pronunciation was forgotten by the Jews since it was suppressed, out of a desire to avoid misuse. The High Priest used it in the Holy of Holies and it survived for some time in the Synagogal Priestly Benediction: here the chant kept up by the choir or by the priests is said to be a survival of the musical screen to shut out the sound of the ineffable name. He who pronounced the name as spelt was guilty of blasphemy. Nevertheless the practical Kabbalists claimed to know the name and to work miracles thereby: such a thaumaturgist was called a *Ba'al Shem* and the last instance known in English was Dr Falk (d. 1782) of whom extraordinary stories of magic are related (*See* pp 245 *sqq.* of J Picciotto's *Sketches*, 1875; *Jew Enc* ; C Duschinsky's *Rabbinate*, 1921.)

BIBLIOGRAPHY.—*See* "Tetragrammaton" in *Jew. Enc.* and other articles therein cited. S. R. Driver in *Studia Biblica* I. (1885), pp. 17–40 of A. Marmorstein's *Old Rabb. doctr. of God* (1927).

TETRAHEDRITE, a mineral consisting typically of copper sulphantimonite, Cu_3SbS_3, but often of complex composition. The copper is usually isomorphously replaced by variable amounts of silver, iron, zinc, mercury, lead or cobalt, and the antimony by arsenic or bismuth. Numerous special names have been applied to varieties differing in chemical composition; the arsenic compound, Cu_3AsS_3, is known as tennantite (after Smithson Tennant). The old German name *Fahlerz* includes both tetrahedrite and tennantite. Tetrahedrite is an important ore of copper, the formula Cu_3SbS_3 corresponding with 57·5% of this metal; it is also largely worked as an ore of silver, of which it sometimes contains as much as 30%. Well-developed crystals are of frequent occurrence; they belong to the tetrahedral class of the cubic system, and their tetrahedral form is a very characteristic feature of the mineral, which for this reason was named tetrahedrite. Fig. 1 shows a combination of a tetrahedron and a triakis-tetrahedron {211}, and fig. 2 a tetrahedron with the rhombic dodecahedron. The colour is steel-grey to iron-black, and the lustre metallic and brilliant. The streak is usually black; sometimes,



TETRAHEDRAL CRYSTALS OF TETRAHEDRITE

however, it is dark cherry-red, and very thin splinters of the mineral then transmit a small amount of blood-red light. The hardness is 4·5, and the specific gravity varies with the composition from 4·4 to 5 1. There is no cleavage, and the fracture is conchoidal

Tetrahedrite occurs in metalliferous veins, usually in the zone of secondary enrichment. Fine groups of crystals, coated on their surface with brassy or brilliantly tarnished chalcopyrite, were formerly found at Herodsfoot mine, near Liskeard in Cornwall. Tennantite occurred as small crystals of cubic or dodecahedral habit in many Cornish copper mines, especially in the neighbourhood of Redruth: it is also found as small, brilliant crystals very rich in faces in the white crystalline dolomite of the Binnenthal in the Valais, Switzerland, and under the name binnite was long considered as a distinct species. (L. J. S.)

TETRAHEDRON: *see* SOLIDS, GEOMETRIC.

TETRAPOD, an animal with four legs; the term is used in zoology to denote collectively the Amphibia, reptiles, birds (*qq.v.*) and mammals (*see* MAMMALIA). The evolution of the tetrapods from their fish ancestors is considered in the article AMPHIBIA.

TETRARCH, a governor of a quarter of a province: Thessaly was divided into tetrarchies by Philip of Macedon and so was Galatia before the Roman Conquest in 169 B C Feudal lords in Palestine were called Tetrarchs and were inferior to Ethnarchs. Tetrarch came to be used generally for a petty prince. Herod the Great was Tetrarch before becoming king. At his request Augustus appointed Pheroras tetrarch of Perea. Other Tetrarchs were Herod's two sons who at his death (4 B.C.) divided his kingdom, Herod Antipas being Tetrarch of Galilee and Philip Tetrarch of Iturea and Trachonitis: the eldest son, Archelaus, was not tetrarch but Ethnarch of Judea, Samaria and Idumea. Herod Agrippa reunited the tetrarchies (A.D. 41–44).

See *Jew. Enc. s v.:* H. Graetz, *History of the Jews* (Philadelphia, 1898) (refs. in index).

TETRASTOÖN, in architecture, a court with a portico or colonnade on all four sides; a peristyle (*q.v.*).

TETRASTYLE, in architecture, a portico with four columns in front, or a building whose main feature is such a portico.

TETRASTYLON, the term given by Vitruvius to a type of atrium (*q v.*) or cavaedium (*q.v.*) in which four columns at the angles of the impluvium (*q.v.*) or central basin supported the roof.

TETSCHEN: *see* DĚČIN.

TETZEL, JOHANN (*c.* 1460–1519), preacher and salesman of papal indulgences, the son of Hans Tetzel, a goldsmith of Leipzig, was born there about 1460. He matriculated at the university in 1482, graduated B.A. in 1487, and in 1489 entered the Dominican convent at Leipzig. He found his vocation as a preacher of indulgences, combining the gifts of a revivalist orator with the shrewdness of an auctioneer. He began in 1502 in the service of the Cardinal-legate Raymond Peraudi; and in the next few years he visited Freiberg (where he extracted 2,000 gulden in

two days), Dresden, Pirna, Leipzig, Zwickau and Görlitz. Later on he was at Nuremberg, Ulm and Innsbruck. He was elected prior of the Dominicans in Glogau in 1505.

Fresh scope was given to his activity in 1517 by archbishop Albrecht of Mainz, who had agreed with Pope Leo X. to pay his first-fruits in cash, on condition that he were allowed to recoup himself by the sale of indulgences. Half the proceeds in his province were to go to him, half to Leo X. for building the basilica of St. Peter's at Rome. Tetzel was appointed general sub-commissioner for indulgences, and was accompanied by a clerk of the Fuggers from whom Albrecht had borrowed the money to pay his first-fruits. Tetzel's efforts irretrievably damaged the complicated and abstruse Catholic doctrine on the subject of indulgences. "As soon as the coin clinks in the chest," he cried, "the soul is freed from purgatory." In June he was at Magdeburg, Halle and Naumburg; the elector of Saxony excluded him from his dominions, but Albrecht's brother, the elector Joachim of Brandenburg, encouraged him at Berlin in the hope of sharing the spoils, and by the connivance of Duke George of Saxony he was permitted to pursue his operations within a few miles of the electoral territory at Wittenberg. Luther was thus roused to publish his momentous ninety-five theses on the subject of indulgences on Oct. 31, 1517.

Through the influence of Conrad Wimpina, rector of Frankfurt, Tetzel was created D.D. of that university, and with Wimpina's assistance he drew up, in Jan. 1518, 106 theses in answer to Luther's. But the storm overwhelmed him: sober Catholics felt that his vulgar extravagances had prejudiced Catholic doctrine, and Miltitz, who was sent from Rome to deal with the situation, administered to him a severe castigation. He hid himself in the Dominican convent at Leipzig in fear of popular violence, and died there on July 4, 1519.

TEUCHIRA, an ancient city of Cyrenaica on the coast 40 m. N.E. of Berenice (mod. *Bengasi*). It was also called Arsinoe in honour of the mother of Berenice. Considerable remains of its ancient walls are preserved; they probably date from the 4th century B.C., but were restored in the time of Justinian, at the expense of the buildings of the ancient city which were laid out on a rectangular plan and of which various remains are left—a palace, another public building with terraces, and two Byzantine churches. The citadel was strongly defended by deep quarries in which numerous tombs have been excavated.

See *Ministero delle Colonie: Notiziario Archaeologico* (1915) 102–110; and authorities for CYRENAICA.

TEUTOBURGER WALD, a mountain range of Germany, stretching north-west to south-east, from west of Osnabräck to south-east of Paderborn for a distance of 70 m. with a width of 2 to 6 m. It consists of a well-marked main chain, with subsidiary ridges in its central part. Its height increases gradually south-eastward culminating in the Völmerstod (1,536 ft.). The greater part of the range is densely wooded.

TEUTOBURGER WALD, BATTLE OF (9 A.D.). At the opening of the Christian era the country between the Rhine and the Vistula was covered by dense forests, and occupied by numerous Germanic tribes. As Julius Caesar had conquered Gaul, so in his turn did Augustus Caesar determine to conquer this region. To it he sent Drusus and Tiberius, both able generals, and by 15 B.C. the Roman frontier was pushed out to the Danube. Between 12 and 9 B.C. Drusus advanced as far as Aliso (probably near Paderborn) on the Lippe, built there a strong fortress, and moved on to the Elbe. Drusus dying at the early age of 30, Tiberius succeeded him in command, and having completed the subjugation of the tribes, in 6 A.D. he was replaced by Quintilius Varus, a man of luxurious habits and disturbed by no cares. He at once began to uproot the old German customs, and by so doing consolidated the tribes against him.

Varus had under his command some 50,000 men. He had administered his province for about a year, when a contingent of Cheruscan (one of the Germanic tribes) troops under the leadership of Arminius returned to their country. Arminius was then in his twenty-fifth year, and had been educated in Rome. He bore the Romans no ill-will until his return, when his indignation was roused by the behaviour of Varus towards his countrymen. Seeing that he was powerless to strike at the Romans covered by their entrenchments, by flattery he gained over Varus, and then in order to draw him away from the Rhenish fortresses persuaded him to move his headquarters to the Weser. This he succeeded in doing.

In the summer of 9 A.D., Varus set out with the XVII., XVIII. and XIX. legions, some cavalry and auxiliaries, in all some 27,000 men to repress a local rising arranged by Arminius. He was warned of the danger, and was urged to secure Arminius and the other Cheruscan chiefs who with their men formed the rear-guard of his column. Refusing to listen to these warnings, from near Minden he entered the forests, followed by an immense train, and headed for Aliso. When the head of the column had become entangled in the brushwood near the hill of Teut, now called Grotenburg, Arminius quitted the rear and followed by his comrades, by means of fire and horn signals roused the tribesmen from the Ems to the Main. As the Romans reached the slopes of the Teutoburg, the German hordes broke in on them from all sides. So trusting and blind was Varus that at first he thought it but rough horse-play. Soon, however, he was disillusioned, and was only able to beat back the incessant assaults by moving towards an open plateau. Here he entrenched.

During Sept. 9, he burnt the *impedimenta* to lighten the column. On the 10th it was again attacked. Though Varus showed great personal bravery he gave no orders, and his troops lost confidence in him. With difficulty they reached the entrance of the Dörn pass but a few miles from Aliso. Here Arminius had determined on his decisive attack. Blocking the further exit he fell upon the flanks of the disheartened column, which broke and was slaughtered. Varus fell upon his own sword as his father had done at Philippi.

The loss of the three Roman legions was more than a staggering blow to Augustus, for it marked a great turning point in European history. It showed that Rome was not invincible. It sent the frontier of the Empire back from the Weser to the Rhine, and so prevented the latinization of what to-day constitutes a large part of modern Germany. It denied to the barbarians of the North a high culture, and it encouraged them to sweep South with a low culture and barbarize western Europe. Tactically this battle is of small account, a Marius or a Caesar would have soon finished with Arminius, but its repercussions, not only on the history of war but on that of civilization, cannot be exaggerated, for they are felt to-day in the age-long quarrel between France and Germany—the Latin and the Teutonic outlooks.

TEUTONI or **TEUTONES,** a tribe of northern Europe who became known to the Romans in the year 103 B.C. when they reinforced the Cimbri (q.v.) after their repulse from Spain by the Celtiberi. In 102 the Teutoni and Ambrones were totally defeated by Marius at Aquae Sextiae (*see* MARIUS). The name of the Teutoni is Celtic in form, and possibly they were really a Celtic tribe, a branch of the Helvetii. But a people of this name was mentioned by the traveller Pytheas as inhabiting the coasts of the northern ocean. Strabo and Velleius classify them as Germani.

TEUTONIC (GERMANIC) LANGUAGES, a comprehensive term for a number of languages, namely English, Frisian, Dutch, Flemish, German (both High and Low) Swedish, Danish, Icelandic, the Norwegian dialects, and the now extinct Gothic, formerly spoken over a large part of Europe. The written records of the various languages date from different periods. Gothic is known to us almost entirely from Ulfilas' translation of the Bible, which dates from the 4th century. English written literature starts with the beginning of the 7th century, though earlier matter may be preserved in certain poems. The earliest known German and Dutch documents date from the 8th and 9th centuries respectively, while Frisian is practically unknown before the 13th century. Scandinavian written literature seems to have be-

gun in the 12th century, but many poems are probably from two to three centuries older. In the North there is a large number of inscriptions of great value for linguistic purposes. They show all stages of development of language from that found in literary times back to a more archaic type even than the Gothic.

The Teutonic languages form a distinct and well-defined group of the Indo-European family (*q.v.*), and belong, together with Celtic, Italic and Greek, to the western or Centum division

The chief characteristic of the Teutonic languages as a whole lies in their treatment of the Indo-European explosive sounds. This characteristic, generally known as Grimm's Law, is due to sound-changes peculiar to Teutonic, though somewhat similar changes may be traced both in Armenian and Celtic. The following abbreviations are used: A S.=Anglo-Saxon, O H G = Old High German; O N =Old Norse; I -E =Indo-European

The voiced aspirates *bh,dh,gh* (Lat. *f,f,h;* Gr ϕ, θ, χ) became voiced spirants, *b,d,ʒ*. After nasals these spirants became explosives (*b,d,g*), and in the first two cases the same change took place initially The I -E. voiceless explosives, *p,t,k*, were preserved only after *s* (*t* also in the I.-E. groups *pt* and *kt*). In all other cases they became voiceless spirants, *f*, þ, χ, (*h*). These new sounds remained (i.) initially; (ii) in combination with other voiceless sounds; (iii) immediately after the (original) accent. In all other cases they became voiced spirants ("Verner's Law"), identical with those arising from I -E *bh,dh,gh*.

The I -E voiced (unaspirated) explosives, *b,d,g*, became voiceless, *p,t,k*.

ʒw arising from I.-E *ghw* or *kw* (*see* above) was reduced (except after nasals) before *u* (perhaps also before I.-E *o*) to ʒ, and in all other cases to *w*.

The I.-E. cons group arising from combination of dental sound +*t* became *ss*, as in Celtic and Latin. The I -E *s* was preserved (i.) initially, (ii) in combination with voiceless sounds, (iii) immediately after the (original) accent. In all other cases it became voiced (*z*). This voiced spirant subsequently became *r* in all Teutonic languages except Gothic, where, however, the distinction between voiced and voiceless spirants is not well preserved

Most of the other consonantal changes are in the nature of assimilation Thus, *bn,dn,zn* before the accent became *pp,tt,kk* (probably through the intermediate stage *bb,dd,gg*); *ln* became *ll; nw* became *nn; dl* became *ll* In some combinations consonants are lost or new consonants developed.

The following changes are found in all Teutonic languages, but took place apparently later than those enumerated above.—

n was lost before χ (*h*), with resultant lengthening of the vowel. Final explosives and nasals were lost

The chief peculiarities of the vowel-system of the earliest known form of Teutonic are.—

It had one vowel (*a*) corresponding to the two vowels *a, o,* found in the other I -E languages

It had also one vowel (*ō*) corresponding to the two vowels *ā, ō*, found in the other I.-E languages.

The other I -E vowels, *ĕ, ĭ, ŭ*, were preserved in the earliest Teutonic Soon after the beginning of our era, however, *e* began to change to *i* before a nasal followed by a consonant The diphthong *ei* became *ī*.

The reduced nasal sounds generally written *n̥, m̥,* arising from *en, ne, em, me,* etc , in unaccented syllables, became *un, um* (rarely *nu, mu*) Similarly the reduced liquid sounds *r̥, l̥,* became *ur, ul* (rarely *ru, lu*).

Accent.—In the I.-E. languages the position of the accent was originally free—*i e* , any syllable in the word could bear the chief accent—variation occurring very frequently, *e.g.*, between different cases of the same noun. This freedom of position must have been retained in Teutonic at the time when voiceless spirants (*f*, þ χ, *s*) became voiced (see above). Eventually, the first syllable of every word came to bear the chief accent, except in certain compound words, especially verbs compounded with prepositions, which were probably long regarded as more or less independent words. This system of accentuation was intimately connected with the principle of alliteration, the essential characteristic of early Teutonic poetry and the dominant factor in family nomenclature.

The description of the phonetic characteristics given above applies in general to the Teutonic group of languages as a whole, and would probably be true for the time about the beginning of the Christian era. Dialectical differences no doubt already existed, but cannot be traced with certainty The language of the earliest Runic inscriptions does not differ very markedly from the type. The principal changes are:—

e became *i*, (i) in the unaccented syllable of dissyllabic and in the least accented syllables of polysyllabic words; (ii.) in accented syllables when the following syllable contained *i, j,* or *u*

i became *e* when the following syllable contained *a, ĕ, ō*.

u became *o* when the following syllable contained *a, ĕ, ō*.

ē became *ā* always.

final *a, e,* were lost

Final long vowels were (in general) shortened (*ī*>*i*, *ō*>*u*).

Final nasals and explosives were lost.

The chief sound-changes in the northern and western languages seem to have taken place in the 6th and 7th centuries. Some were common to all the languages in question, some to English and Scandinavian, some to English and German, others occurred in only one of these languages or a portion of it.

I Among the chief changes common to English, Scandinavian and German we may reckon (1) the loss of final *a* (in Scand. also before final consonants); (2) the loss of unaccented *i, u* after long syllables, (3) the change *z*>*r* before vowels or *g*.

II Among the most important of the changes common to English and Scandinavian must be classed (1) the affection (*umlaut*) of vowels by the vowels (generally *i, u*) of following syllables. In early German the only case of this kind was the affection of *a* by a following *i* and even this seems to have taken place much later In the same category we must reckon (2) the early loss of *h* between sonants, (3) the loss of *n* before *s*

III. Among the chief changes common to English and German were (1) The loss of final *z* In short monosyllables, however, *z* became *r* in High German, as in Scandinavian; (2) The change *z*>*r* before *d* (whereas assimilation took place in Scand); (3) The change *đ*>*d* in all positions (in Scand only initially and after *l*), (4) The lengthening of all consonants (except *r*) before *j* (in Scand only gutturals)

The Frisian dialects agree with English in the phenomena enumerated above and in changes peculiar to these languages, such as (1) the change *ā*>*ō* before nasals; (2) the change *ā*>*ǣ* (later *ē*) in other positions, (3) the labialization of *a* before nasals; (4) the change *a*>*ae* (*e* in Fris) in close syllables (also in open syllables before front vowels); (5) the diphthongization of vowels before *h*; (6) the loss of *n* before þ ; (7) the palatalization of gutturals before front vowels. The differences between the two languages in early times were few (1) *a, e, i,* are diphthongized before *r* followed by a consonant in English, but not in Frisian; (2) the diphthong *ai* became *ā* in English everywhere, but in Frisian only in open syllables (*ē* in close syllables); (3) the diphthong *au* (*aeu*, then) became *ēa* in English, but *ā* in Frisian, (4) *i* was labialized in Frisian, but not in English, before (original) *w* in the following syllable. Frisian texts of the 13th and 14th centuries show many characteristic changes which must have rendered the language almost, if not wholly, unintelligible to an Englishman of the same period, but it is hardly probable that these changes were for the most part of any great antiquity.

Declension—The I -E. languages seem originally to have had three numbers and eight cases. In Teutonic there is scarcely any trace of the dual in nouns All the early Teutonic languages preserved the Nominative, Accusative, Genitive and Dative. The Vocative was kept in Gothic and the Instrumental to a considerable extent in early German, while the earliest Anglo-Saxon preserved many traces of the locative.

The case endings are best preserved in the earliest Northern inscriptions and in Gothic. Whatever changes have taken place have usually tended towards simplification; thus there are but few traces of stem-variation (*ablaut*) between different cases of the same noun.

Adjectives—The treatment of adjectives was more peculiar. In

addition to the old type of declension which conformed to that of the demonstrative pronoun, almost every adjective was inflected also after the model of *n*-stems. This type of inflection occurs chiefly in conjunction with the demonstrative pronoun (definite article).

The comparative of adjectives is formed partly by a suffix *-izan-*, and partly by a suffix *-ōzan-* which is peculiar to Teutonic. Similarly the superlative is formed partly by a suffix *-ista-*, and partly by a new formation *-ōsta-*.

Most of the I.-E. demonstrative pronouns are found in Teutonic, and the peculiarities of their inflection are in general well preserved. The place of the relative pronoun is supplied by the demonstrative or by indeclinable forms. The inflection of the personal and reflexive pronouns is for the most part peculiar to Teutonic.

Conjugation.—The Teutonic verb-system is simpler than that of most of the I.-E. languages. The old Middle Voice is preserved only in Gothic, where it is used as a passive. In the other Teutonic languages only one or two isolated forms remain. In place of the Conjunctive and Optative, there is but one mood which is generally called Conjunctive, though its forms are mostly of Optative origin. There are only two tenses, Present and Preterite, the latter of which is derived partly from the I.-E. Perfect, partly from Aorist or Imperfect formations. A few old Perfects, which have no Presents, retain their original meaning and are generally known as Preterite-presents. In place of the Future the Teutonic languages use either perfective verbs (generally compounded with a preposition) or a periphrasis consisting of the Infinitive with an auxiliary verb.

The conjugation of the Pres. Indic. Act. corresponds in general to that of most of the I.-E. languages. Gothic had also forms for the 1, 2 dual, *bairos, bairats,* which have not been satisfactorily explained. In the other languages there is scarcely any trace of the dual. The conjugation of verbs corresponding to the Greek verbs in *μι* is preserved best in Old High German. A number of archaic forms are preserved in the "verb substantive." The forms of the Conjunctive (Optative) and Imperative correspond in general to those of the other I.-E. languages.

The Preterite formations are of two types, usually termed "strong" and "weak." The latter belong to verbs whose past participle has a stem *-da-* (I.-E. *-tó-*; see below), the former to the remaining verbs. The singular of the strong Preterite is derived from the I.-E. Perfect, while the plural, which in most verbs has a different stem, may come either from the Perfect or from Aorist formations. In the plural the endings were originally accented; hence many verbs show differences not only in the stem vowel but also in the consonants (by Verner's Law, *see* above) between the two numbers. Except in Gothic and Scandinavian the 2 sing. has generally a form (originally Aorist) similar to the plur. The stem of the Conjunctive also agrees with that of the plural.

The "weak" Preterite seems originally to have arisen out of a periphrastic formation of which the second part consisted of Imperfect or Aorist forms of the verb. The short reduplication-syllable, however, is lost in the sing., while the long syllable of the plur. (and dual) is preserved only in Gothic.

The stem of the weak Preterite almost always conforms to that of the past participle. The inflection of the Conjunctive agrees with that of the strong Preterite.

The Infinitive is formed from the present stem with an ending *-an,* and probably was originally a case-form of a verbal noun. In the western languages we find also the Dative of a stem *-anja-* used after a preposition.

The Present Participle has a stem *-and-* (I.-E. *-ont-*) identical with the ending of the 3 plur. Indic., as in the other I.-E. languages; but the Participles in actual use were declined as *-an-* or *-ja-* stems. The unextended stem survives only in substantives. The stem of the Past Participle (Passive) is formed by the suffixes *-to-* and *-no-*, as in the other I.-E. languages. The former occurs as a living formation only in connection with the verbs whose Present stem ends in *-ja-, -ō-, -ē-*. The Past Participle in use with other classes of verbs has a stem *-ena-* or *-ana-*, the former in English and Scandinavian, the latter in Gothic and German. Remains of old Participles in *-to-, -no-* formed otherwise than those in living use may be found in adjectives.

Thus the Teutonic group of languages has many characteristic features which distinguish it from other languages of the same stock, while the morphological differences among the Teutonic languages themselves are comparatively slight and due mainly to the operation of syncretism and other simplifying processes, which have been carried still further, so that the Danish verb has lost all inflection of person and number, while distinction of gender has wholly disappeared in English. In the earlier stages of the Teutonic languages differences of phonology are more marked than those of morphology, and afford surer criteria for determining the relations of these languages to one another. Gothic began at an early date to show marked divergences from the other languages. The Scandinavian languages also certainly underwent a considerable number of peculiar changes before the beginning of their literatures. From the 6th century to the 9th the Scandinavian peoples were practically cut off from communication with other Teutonic nations by the Slavonic occupation of Mecklenburg and eastern Holstein. By the middle of the 7th century the English and Frisian languages were about midway between Scandinavian and German, though they had already developed well-marked characteristics of their own. They doubtless represent the old language of the maritime districts, at one time spoken along the whole of the coast between the present frontiers of Belgium and Denmark. The special characteristics of German in all probability developed in the interior and those of Scandinavian round the Baltic and the Cattegat. From the 8th century onwards the High German (southern) dialects of German differed greatly from those spoken further north owing to the operation of the changes generally known as the "second sound-shifting." The northern dialects, however (Old Saxon and Low Frankish), were essentially German, though both were affected by Frisian influence.

TEUTONIC ORDER, THE, or Teutonic Knights of St. Mary's Hospital at Jerusalem (*Der deutsche Orden, Deutsche Ritter*) was one of the three great military and religious orders which sprang from the CRUSADES (*q.v.*). Later in birth than the Templars and Hospitallers, the Teutonic Order traces its first beginnings from the third Crusade. But it is amidst the privations and plague which attended the siege of Acre, during the third Crusade, that the first certain beginnings of the Order appear. In the winter of 1190–91 certain pious merchants from Bremen and Lübeck (towns with which the Order was still to be connected in the days of its later history) laid the foundations of a hospital in a vessel which they had drawn ashore. Within a few years the foundation apparently became attached to the German Church of St. Mary the Virgin at Jerusalem; and in March 1198 (there being present in the Holy Land a number of Germans, the relics of Henry VI.'s projected crusade), the great

men of the army and the kingdom raised the brethren of the German Hospital of St. Mary to the rank of an order of knights. The original members were thus ennobled; and henceforth it was the rule that only Germans of noble birth could join the Order.

Like the other two great military orders, the Teutonic Order began with charity, developed into a military club and ended as something of a chartered company, exercising rights of sovereignty on the troubled confines of Christendom. Even in its last phase, the Order did not forget its original purpose: it maintained several great hospitals in its new home on the south-east shore of the Baltic, in addition to an *hôtel des invalides* at Marienburg for its sick or aged brethren. But long before that period the Order had begun to find that its true work lay on the eastern frontiers of Germany. In 1228 Christian, bishop of Prussia, who had received from the Polish duke of Masovia a part of Kulmerland as a fief, had founded the knightly Order of Dobrzin, and was attempting to subdue the heathens of Prussia. Unsuccessful in his attempt, he invited the Teutonic Order to come to the rescue, and bestowed on the Order Kulm and some of the frontier towns in his territory, with such lands as it should conquer.

Thus the Order took its place as the founder of one of the marks on the eastern frontier of Germany, and began to play its part in the *Drang nach Osten*, which is perhaps the vitally important thing in the history of Germany from the 12th to the 14th century. Since the days of Adolf of Holstein and Henry the Lion, a movement of German colonization, in which farmers from the Low Countries, merchants from Lubeck and monks of the Cistercian Order all played their parts, had been spreading German influence from the Oder to the Vistula, from the Vistula to the Dwina—to Prague, to Gnesen and even to Novgorod. Of this movement the Teutonic Order became, along with the Hanse, the chosen representative.

In 1229 the Order began the conquest of Prussia, founding fortresses at each step to rivet its conquests (for instance, at Thorn, named after Toron in Palestine), much as the Anglo-Normans had done in their conquest of Wales; and in 1234 the Order established its independence of all authorities except the Papacy, by surrendering its territories to the Holy See and receiving them back again as a fief. The pope gave to those who joined in the work of the Order the privileges of Crusaders; and the knights, supported by numerous donations and large accessions to their ranks, rapidly increased their territories. Already by the beginning of the 14th century these conquests had fundamentally changed the character of the Order. It lost any connection with the East: after the fall of Acre in 1291, the grand master (whose seat had been at Acre, while the German master [*Deutschmeister*] had controlled the Order in Germany) moved first to Venice, and then, in 1308, to Marienburg on the Vistula.

Again, with the accession of large territories, the Order became a governing aristocracy; the original care for the sick, and even the later crusading zeal of the period of conquest, gave way, when conquests were gained and administration was needed, to the problem, half military, half political, of governing a frontier state. The statutes of the Order were altered to suit the new conditions, and a whole system of administration arose. At Marienburg the grand master maintained a magnificent court; round him were the five great dignitaries of the Order, the Grand Commander, the Marshal, the Hospitaller, the Treasurer (*Tressler*) and the Keeper of the Wardrobe (*Trapier*) to see to the clothing of the Order. There was a *Landmeister* for Livonia, and another (the *Deutschmeister*) for the German province, with his seat at Mergentheim in Swabia. Over each of the twenty districts of the Order was set a commander (*Komtur*), with the brethren of his house at his side as advisers.

The concord of the Order at this time with the towns and the Hanse was one of the great causes of its prosperity until the close of the 14th century; and the rupture of that concord in the 15th century was largely responsible for its fall. This political and material strength enabled the Order to weather the storm by which the Templars were destroyed at the beginning of the 14th century. For a time, indeed, the Order lay under papal sentence of excommunication; but the transference of his seat to Marienburg at this time (1308) gave the grand master a basis from which he was able to make easy terms with the pope. Nor was the Order, during the 14th century, at all unfaithful to its original calling. Particularly under the grand master Winrich of Kniprode (1351–1382) it was the school of northern chivalry, engaged in unceasing struggle to defend Christianity against the heathen Lithuanian.

At the height of its glory irretrievable ruin descended upon the Order. The defeat which the Polish king Ladislaus inflicted upon the knights at Tannenberg in 1410 was crushing. It brought Ladislaus little immediate gain; but it stimulated the elements of unrest in Prussia to fresh activity. The discontented clergy, especially in Livonia; the towns, such as Danzig; the native aristocracy, organized in a league (the *Eidechsenbund*, or League of the Lizard), all sought to use their opportunity. It was in vain that the heroic grand master, Henry of Plauen (1410–1413) sought to stem the tide of disaster; he was deposed by the chapter of the Order for his pains. The success of the Hussite raids in Germany gave fresh confidence to the Slavs of Poland. The Order was at variance within itself; some of the houses of the brethren refused to obey the marshal, and the grand master quarrelled with the German master. Above all, there arose in 1440 the Prussian League (*Preussischer Bund*), in which the nobles and towns joined together, nominally for common protection of their rights, but really against the Order. The League naturally sympathized with Poland, not only because Poland was the enemy of the knights, but also because under Poland it hoped to enjoy the practical liberty which Polish anarchy already seemed to offer. The ultimate result was that in 1454 an embassy of the League offered Prussia to the Polish king, and that, after many years of war, the Peace of Thorn (1466) gave to Poland West Prussia, with Marienburg, Thorn, Danzig and other towns, in full possession, and, while leaving East Prussia to the Order, made the Order the vassals of Poland for the territory which it retained. Henceforth the grand master was to sit in the Polish diet on the left of the king, and half of the knights were to be Polish.

Henceforth the Teutonic Order lived in Germany and in Livonia. The master of the latter province had beaten off an attack of the Russians in 1502, and secured a fifty years' peace. But in 1561 another master followed the example of Albert, and received Courland as an hereditary fief from Poland. Henceforth the Order was confined to Germany alone. Nevertheless, it clung to its rights with the conservatism of an ecclesiastical corporation, still maintained its claims to East Prussia and pressed them tenaciously even against the electors of Brandenburg themselves, when they inherited the land on the failure of Albert's descendants in 1618. The French Revolution finally deprived the Order of all its estates, and for a while of its existence. In 1801 the bailiwicks to the west of the Rhine were absorbed by France; in 1809 the Order was entirely suppressed, and its lands went to the secular principalities in which they lay. But in 1840 the Order was resuscitated in Austria as a semi-religious knighthood, closely connected with the Habsburgs. But its real heirs were the Hohenzollerns of Prussia. When Frederick the Great gained West Prussia by the first partition of Poland (1772), he was uniting together once more the dominions of the Order, sundered for 300 years.

TEUTONIC PEOPLES, a comprehensive term for those populations of Europe which speak one or other of the various Teutonic languages, viz, the English-speaking inhabitants of the British Isles, the German-speaking inhabitants of Germany, Austria-Hungary and Switzerland, the Flemish-speaking inhabitants of Belgium, the Scandinavian-speaking inhabitants of Sweden and Norway, practically all the inhabitants of Holland and Denmark, small German and Flemish-speaking communities in

Italy and France, the somewhat larger German and Swedish populations in Russia, and the populations in America, Africa, Australasia, etc., which have emigrated from the same countries. In the British Isles, there is (in addition to the Celtic-speaking elements) a considerable population which claims Celtic nationality though it uses English.

The term "Teutonic," like the other terms ("Germanic," "Gothic," etc.) which are or have been used in the same sense, is of scholastic and not of popular origin, because their common origin has been forgotten. In Tacitus's time, however, a consciousness of their relationship to one another was fully retained. He cites native poems which declared that the Inguaeones, Hermiones and Istaeuones—the three main branches of the Germani (*see* below)—were sprung from three sons of a certain Mannus (perhaps "Man"), himself the son of the god Tuisto, the son of Earth; and a Frankish document at least four centuries later mentions three brothers named Erminus, Inguo and Istio, from whom many nations were descended. In English documents also eponymous national ancestors are grouped in genealogical trees.

In regard to physical features they present at the present time many varieties both of stature and of pigmentation, though on the whole they are probably the tallest and fairest of European peoples. These characteristics must in early days have been as pronounced. Moreover, the tallness and dolichocephaly which now specially mark the more northern peoples of the group appear very prominently in cemeteries of the migration period in Switzerland and other neighbouring countries. On the whole, however, the skeletons found in German and Scandinavian tombs dating even from the earliest period do not show any very remarkable differences from those of the present day. But the most striking characteristics of these peoples occur also to a considerable extent among their eastern and western neighbours, where they can hardly be ascribed altogether to Teutonic admixture.

The neolithic population of Scandinavia was composed of three elements: Food-gatherers (descendants of the epipalaeolithic inhabitants), Megalithic Builders and the People of the Separate Graves. Study of these cultures and their distribution shows that the folk of the Separate Graves were a distinct and bellicose people. Whether their original home lay in Jutland or whether they were continental invaders is disputed; but by the beginning of the bronze age, the Separate Graves' People had succeeded both in dominating and absorbing the other two elements. (*See* ARCHAEOLOGY: *Eastern Europe* and SCANDINAVIAN CIVILIZATION.) As no Teutonic inscriptions are extant from before the 3rd or 4th centuries, it cannot be stated with certainty what types of objects are characteristic of Teutonic civilization in the bronze and earliest iron ages. Yet during the bronze age, a fairly well-defined group of antiquities can be traced covering the basin of the Elbe, Mecklenburg, Holstein, Jutland, southern Sweden and the islands of the Belt, and archaeologists conjecture that these antiquities represent the early civilization of the Teutonic peoples. The civilization was, of course, not wholly of native growth. Strong foreign influence, first from the East Mediterranean and later from Italy, can be distinguished, nor is the influence of Central Europe (the Aunjetitz and the Danubian-Sudetic Tumulus cultures) to be underestimated. But the types introduced from the south have generally undergone considerable modification. The degree of wealth and artistic skill of which many of even the earliest antiquities give evidence is probably due to the importance of the amber trade. Both in eastern and in western Germany the objects found are of somewhat different types pointing to a lower standard of civilization. What peoples inhabited these regions can only be conjectured, but there is a certain amount of evidence from place-names—not altogether satisfactory—that the Celtic peoples at one time extended eastwards throughout the basin of the Weser. With the beginning of the iron age (perhaps *c.* 500–400 B.C.) Celtic influence becomes apparent everywhere. By this time, however, the great Celtic movement towards the south-east had probably begun, so that the Teutonic peoples were now cut off from direct communication with the centres of southern civilization.

HISTORY

The first recognition that the inhabitants of Germany, Holland, etc., were a people distinct from their Celtic neighbours dates from about the middle of the 1st century B.C., when Caesar's conquest of Gaul renders a knowledge of northern Europe more generally accessible. Certain notices relating to individual Teutonic tribes come down from still earlier times. Thus the Cimbri and their allies, who invaded Illyricum, Gaul and Italy in the last years of the preceding century, were for the most part of Teutonic nationality. The Bastarnae also, who in the 3rd century B.C. invaded and settled in the regions between the Carpathians and the Black Sea, are said by ancient writers to have been Teutonic, though they had largely intermarried with the native inhabitants. Again, individual travellers from the time of Pytheas onwards had visited Teutonic countries in the north. The early records, however, do not clearly distinguish the Teutonic peoples from the Celts. From the time of Caesar onwards the former were known to the Romans as "Germani," a name probably of Gaulish origin, first applied to certain Belgic tribes in the basin of the Meuse, who may have come from beyond the Rhine.

At the beginning of our era the Teutonic peoples stretched from the Rhine to the Vistula. Before Caesar's arrival in Gaul they had advanced beyond the Rhine, but in this direction were checked by his campaigns, and, though both banks of the river were occupied by Teutonic tribes throughout the greater part of its course, most of these remained in subjection to the Romans. The eastern-most Teutonic tribe was probably that of the Goths, in the basin of the Vistula, while the farthest south were the Marcomanni and Quadi, in Bohemia and Moravia, districts which had been conquered from the Boii, a Celtic people, shortly before the beginning of our era. Towards the south and west the Teutonic peoples had been pressing the Celts for some considerable time, since the Helvetii formerly extended as far as the Main, while another important Celtic tribe, the Volcae Tectosages, had occupied a still more remote position, which it is impossible now to identify. At this time the Teutonic peoples occupied at least a considerable part of the Scandinavian peninsula.

On what the grouping into Inguaeones, Hermiones and Istaeuones was based, is not certain. Kossinna (*see* bibliography) distinguishes three cultural subdivisions in the civilization of the West Germans in the first century A.D. which more or less correspond to these three groups of peoples. It is probable, however, that these three names have also a religious significance. The name of the Hermiones, who are defined as "central" or "interior" peoples, is probably connected with that of the Irminsul, the sacred pillar of the Old Saxons. The Inguaeones are defined as being "next to the ocean"; but the name can be traced only in Denmark and Sweden, where we find the eponymous hero Ing and the god Yngvi (Frey) respectively. It is likely that the name belonged only to the peoples of the southern Baltic. There were probably many tribes which did not regard themselves as belonging to any of these groups. Tacitus records a variant form of the genealogy (*see* above), according to which Mannus had a larger number of sons, who were regarded as the ancestors of the Suebi, Vandilii, Marsi and others. (*See* SUEBI, VANDALS.)

For a few years at the beginning of the Christian era the part of Germany which lies west of the Elbe was under Roman government; but after the defeat of Varus (A.D. 9) the Rhine and the Danube formed in general the frontiers of the empire. Roman influence was felt both by way of trade and by the employment of German soldiers in the auxiliary forces. In the age of national migrations—from the 4th to the 6th century—the territories of the Teutonic peoples were vastly extended, partly by conquest and partly by arrangement with the Romans. In the east, the Goths ravaged Dacia, Moesia and the coast regions as early as the 3rd century. In the following century the Vandals settled in Pannonia (western Hungary), while the Goths occupied Dacia, which had now been given up by the Romans, and subsequently seized territories to the south of the lower Danube.

The 5th century was the time of the greatest national movements. In 406–7 the Vandals and other tribes invaded Gaul from the east and subsequently took possession of Spain and north-

western Africa. Immediately afterwards the Visigoths invaded Italy and captured Rome; then turning westwards they occupied southern Gaul and Spain. The southern Suebic peoples, the Alamanni and Bavarians, extended their frontiers to the Alps probably about the same time. Not much later a large part of northern Gaul was taken by the Franks, and before the middle of the century the eastern part was occupied by the Burgundians. Several of these movements were due to pressure from the Huns, an eastern people who had conquered many Teutonic tribes and established the centre of their power in Hungary. Their empire broke up after the death of their king Attila in 453. In the latter part of the century the eastern part of Britain was conquered by the Angli, Italy was invaded by the Ostrogoths and northern Gaul subjugated by the Franks. By this time most of southern and western Europe was under Teutonic government.

This great expansion was due to the increasing weakness of the Romans, to pressure of population in Germany, and, specially, to the military strength of the Teutonic nations now far more formidable than in the time of the early empire They were better armed and their power was more concentrated. Thus a dozen different tribes in and around the lower part of the basin of the Rhine in the 1st century, by the end of the 5th century had become subject to one king. This concentration of power provided the kings with greater wealth and with larger permanent bodies of armed men. The motive force towards extension of territories was supplied by military ambition, the growth of a warlike spirit in the North was constantly driving young warriors to seek their fortunes in the service of continental princes

The first half of the 6th century saw the subjugation of the Burgundian and Visigothic portions of Gaul by the Franks and the recovery of Africa by the Romans, which was soon followed by the overthrow of the Ostrogothic kingdom; but some years later Italy was again invaded by the Langobardi (Lombards), the last of the great Teutonic migrations. By this time the old Teutonic lands in eastern Germany, including even the basin of the Elbe had been occupied by Slavonic peoples. Before the end of the century Bohemia and Lower Austria, the basins of the Drave and the Save, had become Slavonic.

The succeeding centuries witness a return to the ethnographical conditions which prevailed before the migration period The Franks and the Langobardi remained in Gaul and Italy, were gradually denationalized and absorbed in the native populations. In Spain Teutonic nationality came to an end with the overthrow of the Visigothic kingdom by the Moors, if not before. Yet throughout the west and south-west the Teutonic frontier remained from fifty to two hundred miles in advance of its position in Roman times. In south-eastern Europe the Teutonic elements were swallowed up by the native and Slavonic populations, a small remnant lingering in the Crimea until probably the 17th century. The political consolidation of the various continental Teutonic peoples (apart from the Danes) in the 8th century led to the gradual recovery of eastern Germany, Lower Austria and the greater part of Styria and Carinthia, though Bohemia, Moravia and the basins of the Vistula and the Warthe have remained mainly Slavonic. In the British Isles the Teutonic element, in spite of temporary checks, eventually became dominant everywhere. Lastly, from the beginning of the 9th century bodies of Scandinavian warriors began to found kingdoms and principalities in all parts of Europe. The settlers, however, did not preserve their nationality, and in almost all cases they were soon absorbed by the populations (Teutonic, Celtic, Latin or Slavonic) which they had conquered Their settlements in Greenland and America came to an end, but Iceland, which was formerly uninhabited, remained a Scandinavian colony.

Form of Government.—Tacitus speaks of tribes which had kings and tribes which had not, the latter apparently being under a number of *principes*, and represents the power of Teutonic kings in general, with reference no doubt primarily to the western tribes, as being of the slightest, while among the Goths, an eastern people, they had somewhat more authority, and for the Swedes he gives a picture of absolutism In harmony with these statements many Northern and probably all the Anglo-Saxon kingly families traced their origin to the gods The Swedes, indeed, and some of the eastern peoples seem to have regarded their kings themselves as at least semi-divine. As the west was most open to foreign influence during the Roman period, the form of government which prevailed here was less primitive, especially as kingship had by this time died out among the Gauls In later times a number of "kings," generally belonging to one family, are frequently found within the same tribe; and the early *principes* were probably persons of similar position.

The *concilium* or tribal assembly figures largely in Tacitus's account of the Germani as the final authority on all matters of first-rate importance. Here the *principes* were chosen, serious charges brought against members of the tribe and youths admitted to the rights of warriors. The duties of opening the proceedings and maintaining order belonged to the priests, so that probably the gathering itself was primarily of a religious character and met, as among the Swedes in later times, in the immediate neighbourhood of the tribal sanctuary. Such religious gatherings were no doubt common to all Teutonic peoples in early times, but it is not certain that among the eastern and northern tribes they were invested with all the powers ascribed to them by Tacitus After his time tribal assemblies are seldom mentioned, and though we hear occasionally, both in England and elsewhere, of a concourse of people being present when a king holds court on high days or religious festivals, there is no evidence that such concourses took part in the discussion of state affairs Indeed, considering the greatly increased size of the kingdoms in later times, it is improbable that they were drawn from any except the immediately adjacent districts. When we hear of deliberations now they are those of the king's council or court, a body consisting partly of members of the royal family and partly of warriors old and young in the personal service of the king. Such bodies of course had always existed (*see* below) and exercised at all times a powerful influence upon the kings, frequently even forcing them into war against their own wishes.

Probably no institution of the Teutonic peoples exercised a greater influence on their history than the *comitatus.* Caesar records that it was customary at tribal assemblies for one or other of the chiefs to propose an expedition He had generally no difficulty in gathering a following, and those who embraced his service were held bound to accompany him to the end, any who drew back being regarded as traitors. Moreover, kings and other distinguished persons kept standing bodies of young warriors, an honour to them in time of peace, as Tacitus says, as well as a protection in war. Chiefs of known prowess and liberality attracted large retinues, and their influence within the tribe, and even beyond, increased proportionately The followers (called by Tacitus *comites,* in England "thegns," among the Franks *antrustiones,* etc.) were expected to remain faithful to their lord even to death; indeed the relationship between the two seems to have reckoned as equivalent to that of father and son.

According to Tacitus it was regarded as a disgrace for a *comes* to survive his lord, and in later times they frequently shared his exile. At the battle of Strassburg in 357, when the Alamannic king Chonodomarius was taken prisoner by the Romans, his two hundred *comites* gave themselves up voluntarily to share his captivity. In return for their services the chief was expected to reward his followers with treasure, arms and horses. If he were a king the reward might take the form of a grant of land, or of jurisdiction over a section of the population subject to him—in early times a village, in later, perhaps, a considerable district. Further, since the grantees as a rule naturally sent their sons into the service of their own lords, such grants tended to become hereditary, and in them we have the origin of the baronage of the middle ages. The origin of the earls or counts, on the other hand, is to be found in the governors of large districts (Tacitus's *principes*), who seem at first generally to have been members of the royal family, though later drawn from the highest barons.

Social Organization.—In the time of Tacitus there were three social classes, viz. nobles, freemen and freedmen, which are met with in later times, though occasionally one of them dis-

appears, *e.g.* the nobility among the Franks and the freedmen (as a distinct class) in the Anglo-Saxon kingdoms, except Kent. Each of these classes was, to a large extent at least, hereditary and had separate rights and privileges of its own. Among the chief of these must be reckoned the wergeld or "man-price." When homicide took place vengeance was regarded as a sacred duty incumbent on the relatives, and sometimes at least the lord also, of the slain man; but, as in the case of any other injury, compensation could be made by a fixed payment. From the evidence of later custom it is probable that the normal payment for a freeman was a hundred head of cattle. The sums paid for members of the other classes were more variable; for the freedman, however, they were always lower, and for the noble higher, sometimes apparently three or four times as high. Similar gradations occur in the compensations paid for various injuries and insults, in fines and, among some tribes, in the value attached to a man's oath. There is uncertainty in regard to both the exact position and numbers of the nobles and freedmen of Tacitus's age.

Groups of family and kindred occupy a prominent position in the accounts of Teutonic society given by Caesar and Tacitus. It was regarded as a universal duty to afford protection to one's kinsmen, to assist them in the redress of wrongs and to exact vengeance or compensation in case of death. Hence to have a numerous kindred was a guarantee of security and influence. The large amounts fixed for the wergelds of nobles and even of freemen were paid no doubt, as in later times, not only by the slayer himself, but by every member of his kindred in proportion to the nearness or remoteness of his relationship; and in like manner they were distributed among the kindred of the slain. The kindred appear also in the tenure of land, and according to Tacitus the tribal armies were drawn up by kindreds. As to the nature of these organizations the evidence is not altogether consistent. Agnatic succession prevailed among the princely families of the Cherusci, and the general account given in the *Germania* implies that this type of organization was normal. On the other hand there are distinct traces of matriliny in Tacitus's works in Northern traditions and in the Salic law.

Marriage.—All the usual forms of marriage were known. Marriage by purchase appears most prominently in Kent and among the Old Saxons, Langobardi and Burgundians. In other nations, *e.g.* the Franks, we find the payment of a very small sum, which is often regarded as symbolic and as a relic of real purchase. Yet this explanation is open to question owing to the very early date at which the regulation appears, and to the fact that in the case of widows the sum specified had to be paid to relatives of the widow herself on the female side, and by preference to those of a younger generation. Again, Tacitus states that the presents of arms and oxen given by the bridegroom at marriage were made to the bride herself and not to her guardian, and such appears to have been the case in the North also from early times. It is not certain, therefore, that marriage by purchase was a universal and primitive Teutonic custom. Of the actual ceremonies practised at marriage little is known. It was preceded, however, by a formal betrothal and accompanied by a feast.

There is no doubt that the marriages of heathen times were often of a kind which could not be permitted after the adoption of Christianity. Among these may be mentioned marriages with brothers' widows and stepmothers, the latter especially in England. Polygamy was known, but limited, both in early and late times, to persons of exceptionally high position, while of polyandry there is hardly any trace. Indeed, the sanctity attached to marriage seems to have struck the Romans as remarkable.

State of Civilization.—It is disputed whether the Teutonic peoples were really settled agricultural communities at the time when they first came into contact with the Romans, shortly before the beginning of our era. That agriculture of some kind was practised is clear from Caesar's account, and Strabo's statement to the contrary must be attributed to ignorance or exaggeration. But Caesar himself regarded the Germani as essentially pastoral peoples and their agriculture as secondary, while Tacitus shows that in his time it was of a primitive character. The husbandry was co-operative, as in later times, and apparently the ploughlands were changed from year to year without any recognition of a two-course or three-course system. Caesar, moreover, says that the clans or kindreds to whom the lands were allotted changed their abodes also from year to year—a statement which gives a certain amount of colour to Strabo's description of the Germani as quasi-nomadic. Yet this representation of early Teutonic life was by no means universally true. Evidence, both archaeological and linguistic proves that the cultivation of cereals in Teutonic lands goes back to a very remote period, while the antiquity even of the ox-plough is attested by the rock-carvings at Tegneby in Bohuslän (Sweden), which date from early in the bronze age. Further, that the tribes were not normally of a migratory character, as Strabo seems to imply, is shown by the existence of sanctuaries of immemorial age and by frontier ramparts like those of the Angrivarii against the Cherusci.

It would seem that Julius Caesar encountered the Germani under somewhat abnormal conditions. Several of the tribes with which he came into collision had been expelled from their own territories by other tribes, and we are expressly told that Ariovistus's troops had not entered a house for fourteen years. Indeed Caesar himself regarded the prevalence of the military spirit as the chief hindrance to the development of agriculture. From this time onwards it was from the west mainly that Roman civilization made its way into Germany; but in earlier ages there are more abundant traces of civilization in the basin of the Elbe than in the districts farther to the west.

All ancient writers emphasize the essentially warlike character of the Germani. Yet Tacitus represents their military equipment as being of a somewhat primitive type. Swords, helmets and coats of mail, he says, were seldom to be seen; in general they were armed only with huge shields, unwieldy spears and darts. Here again he appears to be thinking of the western tribes; for elsewhere he states that some of the eastern peoples were armed with short swords and round shields—which probably were of comparatively small size, like those used in later times. This latter type of equipment prevailed also in the North, as may be seen, *e.g.* from the figures of warriors on the inscribed golden horn found at Gallehus (Jutland) in 1734. The favourite method of attack was by a wedge formation (known later in the North as *svinfylking*), the point being formed by a chosen band of young warriors. Certain tribes, such as the Tencteri, were famous for their horsemen, but the Germani in general preferred to fight on foot. Sometimes also we hear of specially trained forces in which the two arms were combined. Naval warfare is seldom mentioned. The art of sailing seems to have been unknown, and it is probable that down to the 3rd century the only seafaring peoples were those of the Baltic and the Cattegat.

Roman influence brought about a considerable advance in civilization during the early centuries of our era. The cultivation of vegetables and fruit trees seems to have been practically unknown before this period, and almost all their names testify to the source from which they were derived. The mill was introduced in place of the quern hitherto in universal use. Great improvements took place likewise in armour and weapons; the equipment of the warriors whose relics have been found in the Schleswig bog-deposits, dating from the 4th and 5th centuries, appears to have been vastly superior to that which Tacitus represents as normal among the Germani of his day. Yet the types, both in armour and dress, remained essentially Teutonic—or rather Celtic-Teutonic.

Writing.—As to the antiquity of the art of writing among the Teutonic peoples, Tacitus says that certain marks were inscribed on the divining chips, but it is not known whether these were really letters or not. The national type of writing, generally known as Runic, must have been fully developed by the 4th century, when some of its letters were borrowed by Ulfilas (Wulfila) for his new alphabet. (*See* RUNES.) Indeed, by this time it was probably known to most of the Teutonic peoples, for several of the inscriptions found in Jutland and the islands of the Belt can hardly be of later date. The Roman alphabet first came into use among the western and northern Teutonic peoples after

their adoption of Christianity.

Funeral Customs.—Icelandic writers of the 12th and 13th centuries distinguished between an earlier "age of burning" and a later "age of barrows," and the investigations of modern archaeologists in general confirm the distinction, though they have revealed also the burial-places of times antecedent to the age of burning. Throughout the stone age inhumation appears to have been universal, many of the neolithic tombs being chambers of considerable size and constructed with massive blocks of stone. Cremation makes its appearance first in the middle bronze age and, at a later period, in the late bronze age practically displaces the older rite. Although the earliest of the ensuing epoch graves in Gotland contain inhumed remains, cremation is practically the universal rite in the early iron age

The latter practice is the one recognized by Tacitus. In the national migration period, however, it fell into disuse among most of the continental Teutonic peoples, even before their conversion, though practised by the Heruli in the 5th century and by the Old Saxons probably till much later. It came into Britain with the Anglo-Saxon invaders and continued in use in certain districts perhaps until nearly the close of the 6th century. In Scandinavian lands the change noted by Icelandic writers may be dated about the 5th and 6th centuries, though inhumation was certainly known before that time After the 6th century cremation seems not to have been common, if we may trust the sagas, but isolated instances occur as late as the 10th century. Cremation and the use of the barrow are not mutually exclusive, for cremated remains, generally in urns, are often found in barrows

On the other hand inhumation below the surface of the ground, without perceptible trace of a barrow, seems to have been the most usual practice during the national migration period, both in England and on the continent. A special form of funeral rite peculiar to the North was that of cremation on a ship Generally the ship was drawn up on land; but occasionally legendary sagas tell of the burning ship being sent out to sea. Large ships containing human remains have been found in barrows of the viking age. Arms and ornaments are frequently met with, sometimes also horses and human remains which may be those of slaves.

Religion.—The conversion of the Teutonic peoples to Christianity covered some seven centuries The Goths accepted the new religion about the middle of the 4th century, and the Vandals followed their example very quickly In the course of the 5th century it spread to several other nations, including the Gepidae, Burgundians, Rugii and Langobardi. In all these cases the Arian form of Christianity was the one first adopted. The Franks were converted to the Catholic form at the end of the 5th century. The extension of Frankish supremacy over the neighbouring Teutonic peoples brought about the adoption of Christianity by them also, partly under compulsion, the last to be converted being the Old Saxons, in the latter half of the 8th century. The conversion of England began in 597 and was complete in less than a century In the north, after several attempts during the 9th century which met with only temporary success, Christianity was established in Denmark under Harold Bluetooth, about 940–960, and in Norway and Sweden before the end of the century, while in Iceland it obtained public recognition in the year 1000 Many districts in Norway, however, remained heathen until the reign of St. Olaf (1014–1028), and in Sweden for half a century later

Our knowledge of the beliefs and forms of worship which prevailed before the adoption of Christianity, is due chiefly to Icelandic literary men of the 12th and 13th centuries, who gave accounts of many legends which had come down to them by oral tradition, besides committing to writing a number of ancient poems. Icelandic history is unique in this respect In the literatures of other Teutonic countries we have only occasional references to the religious rites of heathen times, and these are generally in no way comparable to the detailed accounts given in Icelandic writings. Hence it is often difficult to decide whether a given rite or legend which is mentioned only in Icelandic literature was really peculiar to that country alone or to the North generally, or was once common to all Teutonic peoples.

A number of gods were certainly known both in England and among many, if not all, the Teutonic peoples of the continent, as well as in the North. Among these were Odin (Woden), Thor (Thunor) and Týr (Ti); so also Frigg (Frig), the wife of Odin. The evidence that Balder, the son of Odin, was once known in Germany, is doubtful. Heimdallr, the watchman of the gods and Ullr, the stepson of Thor, as well as Hoenir, Bragi and most of the other less prominent gods, were also probably peculiar to the North, though Ullr at least was known in Denmark. Some of these deities may originally have been local. Indeed, such may have been the case with Frey, the chief god of the North after Thor and Odin. Tradition uniformly points to Uppsala as the original home of his cult. But both he and his sister Freyia were probably specialized forms of a divinity which had once been more widely known. Their father, Niórðr, the god of wealth, a somewhat less important figure, corresponds in name to the goddess Nerthus (Hertha), worshipped by a number of tribes, including the Angli, round the coasts of the southern Baltic.

Tacitus describes her as "Mother Earth," and his account of her cult bears a remarkable resemblance to the ceremonies associated in later times with Frey. This family of deities were collectively known as Vanir, and are said to have once been hostile to the Aesir, to whom Odin belonged. Their worship was generally connected with peace and plenty, just as that of Odin was chiefly bound up with war. Gefion was another goddess who may represent a later form of Nerthus. In her case tradition points distinctly to a connection with Denmark (Sjaelland). On the other hand, the portraiture of Skaði, the wife of Niörðr, seems to point to a Finnish or Lappish origin.

Some of the deities known to us from German and English sources seem also to have been of a local or tribal character. Such doubtless was Fosite, to whom Heligoland was sacred. Saxnot (Seaxneat), from whom the kings of Essex claimed descent, was probably a god of the Saxons. Holda, who is known only from the folklore of later times, appears to have been a German counterpart of Nerthus Ing, connected with Denmark in Anglo-Saxon tradition, was in all probability the eponymous ancestor of the Inguaeones. (*See* above.) His name connects him, too, with the god Frey, who was also called Yngvifreyr and Ingunarfreyr, and he must at one time have been closely associated with Nerthus. The relationship of Ing to the Inguaeones is paralleled by that of Irmin to the Hermiones. (*See* above.) He may be the deity whom Tacitus called "Hercules."

Some of these eponymous ancestors may be regarded as heroes rather than gods, and classed with such persons, as Skiöldr, the eponymous ancestor of the Danish royal family, who is not generally included in the Northern pantheon But the line of division between the human and the divine is not very definite. The royal family of Norway claimed descent from Frey, and many royal families, both English and Northern, from Woden (Odin). Indeed, several legendary kings are described as sons of the latter Sometimes, again, the relationship is of a conjugal character. Skioldr, though hardly a god himself, is the husband of the goddess Gefion. So we find Freyia's priest described as her husband and Frey's priestess as his wife, and there is no reason for regarding such cases as exceptional.

It is seldom easy to distinguish between gods and heroes, but much more difficult to draw a line between the former and other classes of supernatural beings, such as the "giants" (O.N. *iötnar*, A S. *eotenas*). Here again we have intermarriage. Skaði, the wife of Niorðr, and Gerðr, the wife of Frey, were the daughters of the giants Thiazi and Gymir respectively, though Skaði is always reckoned as a goddess. Loki was of giant birth; but he is always reckoned among the gods, and we find him constantly in their company, in spite of his malevolent disposition. In general the giants were regarded as hostile to both gods and men. Often they are represented as living a primitive life in caves and desolate places, and their character is usually ferocious. But there are exceptions even among the male giants, such as Aegir, whom we find on friendly terms with the gods. We may note that some of the leading families of Norway claimed descent from giants, especially from

Thrymr, the chief opponent of Thor. In such cases there may be some connection between the giants and the semi-civilized (Finnish or Lappish) communities of the mountainous districts. This connection is more clear in the case of Thórgerðr Hölgabrúðr, who is known chiefly from the extreme veneration paid to her by Haakon, earl of Lade (+995). According to one story she was the daughter of Hölgi, the eponymous king of Halogaland (northern Norway); according to another she was the wife of Hölgi and daughter of Gusi, king of the Fins.

Another class of supernatural beings was that of the dwarfs. They were distinguished chiefly for their cunning and for skill in working metals. More important than these from a religious point of view were the elves (O.N. *álfar*, A.S. *ylfe*), who certainly received worship, at all events in the North. They are almost always spoken of collectively and generally represented as beneficent. In some respects, *e.g.*, in the fact that they are often said to inhabit barrows, they seem to be connected with the souls of the dead. In other cases, however, they are hardly to be distinguished from spirits (the Icel. *landvaettir*, etc.) which may be regarded as *genii locorum.*

There were yet other classes of supernatural beings. The *fylgiur* and *hamingiur* of Northern belief, are of two kinds, though the names seem not always to be clearly distinguished. Sometimes the *fylgia* is represented as a kind of attendant spirit, belonging to each individual person. It may be seen, generally in animal form, in visions or by persons of second sight, but to see one's own *fylgia* is a sign of impending death. In other cases the *fylgiur* (or perhaps more correctly the *hamingiur*) apparently belong to the whole family. These appear as maidens.

Human beings, especially kings and other distinguished persons, were not infrequently honoured with worship after death. In Sweden during the 9th century we have trustworthy record of the formal deification of a dead king and of the erection of a temple in his honour. In general the dead were believed to retain their faculties to a certain extent in or near the place where they were buried, and stories are told of the resistance offered by them to tomb-robbers. They were credited with the power of helping their friends (and likewise of injuring other people) very much in the same way as they had done in life. Hence the possession of the remains of a chief who had been both popular and prosperous was regarded as highly desirable.

The blessings which kings were expected to bestow upon their subjects, in life as well as after death, were partly of a supernatural character. Chief among them was that of securing the fertility of the crops. The prevalence of famine among the Swedes was attributed to the king's remissness in performing sacrificial functions; and on more than one occasion kings are said to have been put to death for this reason. Under similar circumstances Burgundian kings were deposed. In connection with this attribution of superhuman powers, we may mention also the widespread belief that certain persons had the faculty of "changing shape," and especially of assuming the forms of animals. (*See* LYCANTHROPY.)

We hear occasionally of sacred animals. Tacitus tells of horses consecrated to the service of the gods, and of omens drawn from them, and we meet again with such horses in Norway nearly a thousand years later. In the same country we find the legend of a king who worshiped a cow. Northern mythology speaks also of theriomorphic demons, the chief of which were Midgarðsormr, the "world-serpent," and Fenrisulfr, a monster wolf, the enemies of Thor and Odin respectively. These beings are doubtless due in part to poetic imagination, working on a substratum of primitive religious belief. Tacitus states that the ancient Germans had no images of the gods. But he does speak of certain sacred symbols which he defines elsewhere as figures of wild beasts. One of the chief objects of veneration among the Cimbri is said to have been a brazen bull.

The Quadi are said to have considered their swords divine. Worship was paid, especially in the North, to rocks and stone cairns, while springs and pools also were frequently regarded as sacred in all Teutonic lands. But, on the whole, the most prominent characteristic of Teutonic religion, in early and later times, is the sanctity attached to certain trees and groves, though in such cases there is often a doubt as to whether the tree itself was worshipped or whether it was regarded as the abode of a god or spirit. The sanctuaries mentioned by Tacitus seem always to have been groves, and in later times we have references to such places in all Teutonic lands. One of the most famous was that in or beside which stood the great temple of Uppsala. Here also must be mentioned the Swedish Vårdträd or "guardian tree," which down to our own time is supposed to grant protection and prosperity to the household to which it belongs. One of the most striking conceptions of Northern mythology is that of the "world-tree," Yggdrasil's Ash, which sheltered all living beings. The description given of it recalls in many respects that of a particularly holy tree which stood beside the temple at Uppsala. For the idea we may compare the Irminsul, a great wooden pillar which appears to have been the chief object of worship among the Old Saxons, and which is described as *universalis columna quasi sustinens omnia.*

The Northern sanctuaries of later times were generally buildings constructed of wood or other materials. A space apparently partitioned off contained figures of Thor or Frey and perhaps other gods, together with an altar on which burned a perpetual fire. In the main body of the temple were held the sacrificial feasts. The presiding priest seems always to have been the chief to whom the temple belonged, for there is no evidence for the existence of a special priestly class in the North. In England, however, the priests were never allowed to bear arms. There is record also of priests among the Burgundians and Goths, while in Tacitus's time they held a very prominent position in German society. Among all Teutonic peoples from the time of the Cimbri onwards we frequently hear also of holy women whose duties were concerned chiefly with divination. Sometimes, indeed, as in the case of Veleda, a prophetess of the Bructeri, during Vespasian's reign, they were regarded practically as deities.

Of religious ceremonies the most important was sacrifice. The victims were of various kinds. Those offered to Odin (Woden) were generally, if not always, men, from the time of Tacitus onwards. Human sacrifices to Thor and the other gods are not often mentioned. The animals consumed at the sacrificial banquets were chiefly horses, but included oxen and boars. At human sacrifices, however, dogs and hawks were often offered with the men. At all sacrifices it seems to have been customary to practise divination; in connection with human sacrifice we have record of this rite from the time of the Cimbri. One custom which was regarded as a sacrifice was the dedication of an enemy's army to the gods, especially Odin. This custom, which prevailed from the earliest times, involved the total destruction of the defeated army, together with everything belonging to them. In general the chief sacrificial festivals seem to have taken place at fixed times in the year, one in early or mid-autumn, another at mid-winter and a third during the spring. Sacrifices on an exceptionally large scale were held at Uppsala and Leire every nine years, at the former place about the time of the spring equinox, at the latter in the early part of January.

Beside the belief that the dead retained a conscious existence in or near the place where they were buried, and that they were able to confer blessings upon their friends, we find that the souls of the dead passed to the realm of Hel, who in Northern mythology is represented as the daughter of Loki. Again, those who had fallen in battle were supposed to go to Valhalla, where they became warriors in Odin's service. This last belief seems to have been connected at one time with the practice of cremation. In conclusion it must be mentioned that even the life of the gods was not to be for ever. A day was to come when Odin and Thor would fall in conflict with the wolf and the world-serpent, when the abode of the gods would be destroyed by fire and the earth sink into the sea. But the destruction was not to be final; in the future the gods of a younger generation would govern a better world. How far these beliefs were common to the Teutonic peoples as a whole cannot be determined with certainty. Some think them peculiar to the mythology of Norway and Iceland, and largely due to Christian influence. But very similar ideas in

some respects were current among the ancient Gauls

TEVIOTDALE, valley of the Teviot, Roxburghshire, Scotland In a limited sense the word describes the stretch above Hawick (9 m) and, in a wider sense, the whole vale, extending in a north-easterly direction from Teviothead nearly to the confines of the parish of Roxburgh (23 m) Branxholm tower, the peel of Goldielands, and Harden castle (on Harden burn, a tributary of Northwick water) are spots familiar through the writings of Sir Walter Scott and many Border ballads. Five m. to the east of Hawick stands the hill of Ruberslaw (1,392 ft.). Among the crags on its summit is the rock, still called "Peden's chair," from which Alexander Peden preached to conventicles of Covenanters Below Hawick are Minto, Hassendean—the Hazeldean of Sir Walter Scott's song, "Jock o' Hazeldean"—and Ancrum

TEWFIK, AHMED PASHA (1845–), Turkish statesman, was born in Constantinople on Feb. 11, 1845, the son of Ismail Hakki Pasha In 1866 he went to the ministry of foreign affairs, where he spent six years After acting as first secretary to the Turkish legation in Athens, he was sent to St. Petersburg (Leningrad), where in 1877 he received Prince Gorchakov's note declaring war. The following year he became Turkish minister in Athens, in 1885 he went to Berlin as ambassador, and remained there for 10 years. From 1895 to 1909 he was minister of foreign affairs. After the Young Turk revolution he became grand vizier, and in 1909 was sent to London as ambassador, where he remained till 1914. In 1919 he was reappointed grand vizier, afterwards becoming president of the Senate, and in 1921 he attended the London Conference arranged by the Supreme Council of the Allies. He retired in 1922. During his long career of more than 60 years, Tewfik Pasha played an important part in Turkish affairs. His conciliatory spirit won him universal admiration and the agreements which he concluded with the Balkan States did much to improve relations between these States and Turkey.

TEWFIK PASHA (1852–1892), khedive of Egypt, son of the Khedive Ismail, was born on Nov 15, 1852. With the alteration of the succession law in 1866 Tewfik became heir apparent. In 1878 he was appointed president of the council after the dismissal of Nubar Pasha. He held this office only for a few months; he then returned to his estate, but was soon recalled to public life. On June 26, 1879, Ismail, at the instance of Great Britain and France, was deposed by the sultan, who sent orders at the same time that Tewfik should be proclaimed khedive. The new khedive was little pleased at the honour thrust upon him at a moment when Egypt was in a chaotic state. Disorder prevailed until November 1879, when the dual control was re-established by the governments of Great Britain and France. For over two years Baring (afterwards Lord Cromer), Auckland Colvin, and de Blignières practically governed the country, endeavouring to institute reforms while possessing no means of coercion. During all this time the disaffection in the Egyptian army was increasing. Tewfik has been blamed for his failure to take a firm line with the rebels, but his attitude was governed by his relations with Great Britain and France, and he was unable to control events. For the anti-foreign movement which culminated in the revolt of Arabi *see* ARABI PASHA and EGYPT.

Before the bombardment of Alexandria began it was suggested to Tewfik that he should leave the city and embark either upon a man-of-war belonging to one of the neutral powers, or in his own yacht, or in a mail steamer which was then in the port. His answer was, "I am still khedive, and I remain with my people in the hour of their danger." At his palace of Ramleh, 3 m. from the town, he was beyond reach of the shells, but his life was nevertheless imperilled. When the rebel soldiers attacked the palace he escaped to another palace after going through the burning streets of Alexandria. Here he was obliged to agree that a guard of British bluejackets protect him from further risk.

In 1884 Baring went back to Egypt as diplomatic agent and consul-general of Great Britain. His first task was to demand that Tewfik should abandon the Sudan. Tewfik gave his consent with natural reluctance, but, having consented, he did everything he could to ensure the success of the policy which Baring had been sent to carry out. He behaved with equal propriety during the negotiations between Drummond Wolff and the Turkish envoy, Mukhtar Pasha, in 1886. The sultan was his suzerain; in Great Britain he recognized his protector: to the representative of each he endeavoured to show friendliness and esteem. As time went on his confidence in Baring increased, until at last he deferred to the British agent in almost everything. He took a great interest in irrigation, education and justice

In private life Tewfik was courteous and amiable. He had no desire to keep up the unapproachable state of an oriental ruler. Indeed, in many ways his manners and habits were less oriental than European He married in 1873 his kinswoman, Amina Hanem, with whom he lived very happily. She was his only wife and Tewfik was a strong advocate of monogamy. He died on Jan. 7, 1892, at the Heluan palace near Cairo, and was succeeded by his eldest son, Abbas II (*q v*).

A warm tribute to Tewfik's many admirable qualities was paid by Baring (Lord Cromer) in his report on the administration of Egypt for 1891 (see *Egypt*, No. 3, 1892, pp. 1 and 2).

TEWKESBURY, a town in Gloucestershire, England, 15½ m N.E. of Gloucester by the L M S R, on the Warwickshire Avon, close to its junction with the Severn. Pop. (1921) 4,704 The Severn is crossed by an iron bridge of 170 ft. span Of the Benedictine abbey, one of the richest foundations in England, refounded and enlarged in the 12th century on the site of an ancient hermitage and Saxon monastery, there only remain the gate and a few other fragments. The abbey church, consecrated in 1125, is a magnificent specimen of early Norman. One of the most remarkable features of the building is the unique western front, the central part of which is occupied by one vast arch extending from the ground to the roof. Originally it was filled in with Norman windows, but a Perpendicular window now occupies the space. The whole building underwent restoration in the Decorated period, and of this style it is one of the finest existing examples. The Norman columns in the choir still exist; but above them rises a grand superstructure of Decorated work. The elegant clerestory windows are of the 14th century, with stained glass of the same date. There are two organs, one dating from the early 17th century. There are a grammar school (1625) and a number of charities and almshouses Tewkesbury is chiefly dependent on agricultural trade and milling

Roman remains prove that the earliest settlement near Tewkesbury was a military encampment against the British. It was the

site of a Saxon castle and monastery, and its position led to the growth of a town, which was a borough with a market in 1087. It was subsequently granted to Earl Robert of Gloucester. Charters were granted in 1107, 1337, 1574 (when the borough was incorporated), 1604, 1605, 1609, 1685, 1698 and 1835. Several ancient fairs were granted, but one fair only is now held, on October 10. It is a pleasure fair and a fair for hiring servants.

Cloth-making lasted from the 11th century until the 18th; gloving in the 17th was followed by worsted-combing in the 18th; cotton-thread lace-making, introduced in 1825, collapsed about 1862, and the manufacture of mustard ceased at the end of the 18th century. Stocking-frame knitting was the chief trade in 1830, but has been replaced by the boot and shoe trade. (X.)

Battle of Tewkesbury.—This battle, fought on May 3, 1471, closed the long conflict in England of the Wars of the Roses. The Yorkist victory at Barnet (*q.v.*), less than three weeks before, marked the ruin of the Lancastrian cause; Tewkesbury was a last desperate venture. Contrary winds had delayed the passage from France of Queen Margaret, wife of the imprisoned King Henry VI., and with a small body of Lancastrian supporters she landed in the West of England on the day of the disaster at Barnet. With her was her young son, Edward prince of Wales. The duke of Somerset and other survivors of the defeated army a few days later joined her standard. Margaret wished to return to France, but was persuaded that the Lancastrian strength in the West was unbroken. Adherents were recruited from Devon and Somerset as Margaret struck inland towards the Welsh border, hoping to join forces with Jasper Tudor. Edward IV., at Windsor, gathered an army and moved westwards to intercept the invaders, who after forced marches found the city of Gloucester hostile and its gates closed against them. They struggled on to Tewkesbury, utterly exhausted. King Edward arrived the same evening.

Somerset, commanding the Queen's forces, accepted battle next morning. The position chosen was a strong one, on the gentle slope where the broad Severn flows through the valley. It was much cut up by dykes and hedges, and declivities, through which small watercourses passed, protected both flanks. The town and river were at the rear. As at Barnet, each opposing army was drawn up in three divisions, Edward commanding the Yorkist centre and Richard duke of Gloucester and Lord Hastings the two wings. Little impression was made by Edward's attack, till Somerset, whose ranks were being depleted by the fire of the Yorkist artillery and archers, led the Lancastrian right in an impetuous charge on the King's line. It was not supported. Lord Wenlock and the earl of Devon, with the Lancastrian centre and left divisions, kept their ground. The charge failed, and Somerset was driven back with heavy loss. He suspected treachery, and in the subsequent rout was said to have cleft the skull of Lord Wenlock with his battle-axe for not taking part in the charge.

Pursuing their advantage in the confusion, the Yorkists broke into the Lancastrian main position, forcing their enemy back to the town and Severn banks, where great slaughter ensued. A riverside field to this day bears the name of "Bloody Meadow." Edward prince of Wales was slain when crying for mercy; the earl of Devon and other nobles perished. Somerset himself, with Langstrother the treasurer and many fugitives gained sanctuary in Tewkesbury Abbey, from which they were forcibly taken and after summary trial were executed. Next day Queen Margaret, who had fled to a neighbouring convent, was made prisoner. On the night of Edward IV.'s return from the victory, King Henry VI. was murdered in the Tower of London. The death of Edward prince of Wales on the battlefield left the English throne with no direct heir in the Lancastrian line. (W. G. B.)

TEXARKANA (tĕk-sahr-kăn′a), an urban community formed of two cities, on each side of the Texas and Arkansas boundary line, U.S.A., 165 m. E. by N. of Dallas; on Federal highways 67 and 71, and served by the Kansas City Southern, the Missouri Pacific, the St. Louis South Western, and the Texas and Pacific railways. Pop. (1920) 19,737 (70% native white and 28% negroes) estimated locally at over 32,000 in 1928. The Texas city, Bowie county, had a population of 11,480 in 1920; Arkansas city, county seat of Miller county, had 8,257. Of necessity the cities have separate municipal governments, but commercially, industrially, and socially they are a unit. The assessed valuation of Greater Texarkana was $19,739,732 for 1927. The first permanent settlement was made in 1874. Texarkana, Texas, was incorporated in 1875; Texarkana, Arkansas, in 1881.

TEXAS, popularly known as the "Lone Star State," is a south-central State of the United States of America. It extends from 93° 31′ to 106° 38′ W. long. and from 25° 51′ to 36° 30′ N. latitude. A western projection is bounded north by New Mexico, but the main portion is bounded north by Oklahoma, from which it is separated in part by the Red river. On the east the northern projection is bounded by Oklahoma, but the main portion is bounded by Arkansas and Louisiana, the Sabine river separating it in part from Louisiana. On the south-east the State is bounded by the Gulf of Mexico, the coast line being about 400 m., or, counting all irregularities and inlets, 973 m. long. On the south-west Texas is bordered by Mexico from which it is separated by the Rio Grande river. On the west, by New Mexico.

Physical Features.—Physiographically, there are four provinces. In the south-east are the West Gulf plains, a part of the Coastal plain province of the United States. Thence westward to the 100th meridian are the prairies, the south-westward extension of the Prairie plain province of the United States. The Great

MAIN STREET, ONE OF THE CHIEF THOROUGHFARES OF FORT WORTH, TEXAS

Plains (really a plateau) comprise the western half of the State, except a mountainous area in the west which belongs to the Basin Range province. The mountains of the Basin Range region, known in Texas as the Trans-Pecos province, rise in El Capitan, a peak of the Guadalupe mountains in Culberson county, to 9,020 ft., (the greatest elevation in the State), and the Great Plains have a maximum elevation in northern Texas exceeding 4,000 ft., but from these heights the surface descends to sea-level and the mean elevation of the State is about 1,700 feet. The Gulf plains are bordered along the Gulf of Mexico by a series of long narrow

islands and peninsulas, or sand-bars. Padre, the longest of these islands, extends northward from the mouth of the Rio Grande more than 100 miles. Back of the island sand-bars are the quiet waters of lagoons, and at the mouths of rivers are several bays indenting the mainland; these bays were formed by only a slight subsidence of the land and the rivers are fast filling them with deposits of silt. For 20 m. or more inland in the north and for 50 m. inland in the south the Gulf plains are low and flat, seldom rising as much as 100 ft above the sea, but farther west the surface is more broken and rises to a maximum of 700 feet.

Along a line drawn approximately south-south-west from the south-east corner of Oklahoma, the north-west part of the Gulf plains merges with the Prairie plains. The north-east portion of the Texas Prairie plains is only gently rolling, but the south portion is quite rugged, and the west half rises in a succession of scarps or steps to an elevation of 2,500 ft. at the beginning of the Great Plains province of the State. South of the parallel of the southern boundary of New Mexico the Great Plains province is known as the Edwards plateau; between the Edwards plateau and the valley of the Canadian river, as the Llano Estacado, or Staked plains; and north of the Canadian valley as the North plains. The eastern and southern parts of the Edwards plateau and the eastern margin of the Llano Estacado have been made by headward erosion of streams, but the central portion of the Edwards plateau and nearly all the Llano Estacado have a notably even surface rising slowly to the north-west In the south-eastern corner of the Trans-Pecos province is a smaller plain known as the Stockton plateau, but the remaining portion of this province is traversed from north-west to south-east by isolated mountains of the Basin Range or block mountain type.

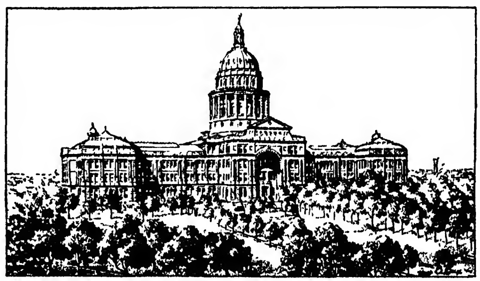
The northern portion of the Panhandle is drained by the Canadian river eastward into Arkansas and thence to the Mississippi The south portion of the northern Panhandle and a strip along the north border of the State, east of the Panhandle, is drained by the Red river south-eastward into the Mississippi. The rest of the State is drained south-east directly into the Gulf of Mexico. The Rio Grande and its principal tributary, the Pecos, drain narrow basins in the south-west; these two rivers and the Canadian river rise in the Rocky Mountains in Colorado and New Mexico, but all the other rivers by which the State is drained rise within its borders. The Red, Brazos, Colorado, Guadalupe and the Nueces rise on the east or south-east border of the Great Plains; the Sabine and the Trinity on the Prairie plains; and numerous small streams on the Coastal plain. In the Great Plains region and in the Trans-Pecos province the rivers have cut deep canyons, and the character of the longer rivers in their upper courses varies from mere rivulets late in summer to swift and powerful streams during spring freshets. Most of the large Texas rivers have deposited great quantities of silt along their lower courses on the Coastal plain, where the current is often sluggish and the banks are periodically overflowed.

Soils.—The Coastal plain has for the most part a light sandy soil, but there is a fertile alluvium in the river bottoms and good clay soil on some of the uplands. The eastern part of the Prairie plains is a belt known as the Black Prairie which has a rich black soil derived from Upper Cretaceous limestone; immediately west of this is another belt with a thinner soil derived from Lower Cretaceous rocks; a southern part of the same plains has a soil derived from granite; a large area in the north-west has a reddish clay soil derived from Permian rocks and a variety of soils—good black soils and inferior sandy and clay soils—derived from Carboniferous rocks. A very thin soil covers the Edwards plateau, but on the Llano Estacado are brownish and reddish loams derived from the sediments of a Neocene lake.

Flora and Fauna.—The arboreal flora of Louisiana and Arkansas extends into north-eastern Texas, conformable with the Coastal plain, where, immediately south of the Colorado river, the great pine belt of the Atlantic and Gulf coasts terminates. The flora of the Great Plains region, consisting principally of nutritious grasses, enters the north-west portion of the State and extends south to the Edwards plateau and east into the Prairie plains region. The peculiar plants of the Rocky Mountain plateaux penetrate into the Trans-Pecos region, while north Mexican flora crosses the Rio Grande in the south-west. The central region is a transition ground where these floras find representation generally in deteriorated and dwarfed species. The long-leaf pine is the dominant forest tree on the uplands of the Coastal plain, north of the Colorado river, for 100 m. or more from the coast; further inland and especially in the north-eastern corner of the State it is succeeded by the short-leaf pine. Between the rising swells of long-leaf pine lands are thickets of hawthorn, holly, privet, plane trees and magnolias. Loblolly pine, cypress, oaks, hickory, ash, pecan, maple, beech and a few other deciduous trees are interspersed among both the long-leaf and short-leaf pines, and the proportion of deciduous trees increases to the westward. In the broad river valleys of the eastern part of the Prairie plains region are forests and isolated groves consisting principally of pecan, cypress, cottonwood and several species of oak. A low growth of mesquite and other shrubs and vines is found on upland areas in the eastern half of the Prairie plains. The western half of these plains has only a few trees along the water courses, and some scraggy oak, juniper, mesquite and cedar in the more hilly sections In the canyons of the Edwards plateau grow the pecan, live oak, sycamore, elm, walnut and cypress; on the hilly dissected borders of the same plateau are cedars, dwarf and scrubby oak, and higher up are occasional patches of stunted oak.

Only a few of the large wild animals remain, but animal life is still varied, for it includes and is a meeting ground for species common to northern, eastern and western United States and many species of Mexico White-tailed Sonora and grey mule-deer, and a few antelopes are found in the south-western counties Louisiana bears still inhabit the inaccessible cane-brakes near the coast, and in the western mountains black and cinnamon bears are occasionally found. Coyotes, jack rabbits and prairie dogs are common on the plains. The Texas game birds consist chiefly of plover, snipe, teal, mallard and wild geese. Alligators are found in the low coast region and are especially numerous in the Nueces river. The horned-toad is the most common Texas lizard, except in the western counties where rock lizards are numerous. Among venomous snakes the coral snake is common along the coast, the copperhead along the wooded banks of creeks and rivers, the cottonmouth in all parts of the State, except the most arid, the "side wiper" or massasauga and ground rattlesnake in all sections.

Climate.—In the region of Galveston, along the northern section of the coast, where southerly and south-easterly winds from the Gulf prevail throughout the year, the climate is warm, moist and equable, but the moisture decreases westward and south-westward, and the equability, partly because of northerly winds during the winter months, decreases in all directions inland. The mean annual temperature decreases to the north-westward with an increase of both altitude and latitude, ranging from 73° F in the lower Rio Grande valley to 55° F in the northern portion of the Panhandle Along the coast the average number of days during a year in which the temperature falls below the freezing-point is only three or four, but in the Panhandle this average is from 100 to 115. The average annual rainfall decreases quite regularly westward and south-westward from 46 in. at Galveston

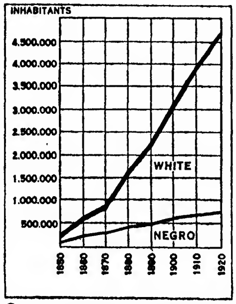


BY COURTESY OF THE AUSTIN CHAMBER OF COMMERCE

THE STATE CAPITOL AT AUSTIN, TEXAS

to 9 in. at El Paso. In middle, eastern and north-eastern Texas the spring months are the wettest and winter months are the driest. In western and south-western Texas the summer months are the wettest and spring months the driest. In these sections irrigation or dry-land farming is necessary for the best results in agriculture. The average annual snowfall for the State is about 5 in. ranging from 19 in. in the northern portion of the Panhandle, to scarcely any along the coast and lower Rio Grande.

Population.—In June, 1928, the population of Texas, according to the estimate of the Federal Census Bureau, was 5,487,000. This was 823,773 more than in 1920 when the actual count was 4,663,228. The estimated increase was based upon the rate of growth between 1910 and 1920, which was 19·7%. In 1910 the population was 3,896,542; in 1900 it was 3,048,710. In 1920 Texas ranked fifth among the States in total population, but in density it ranked only 35th, with 17·8 inhabitants per square mile. This is about one-half the average density for the United States as a whole. There were 18 counties with a density of over 55 inhabitants per square mile. These are found chiefly in a strip from Fort Worth and Dallas north-east to the Red river and south-west through Waco, Austin and San Antonio, with a branch strip south-east from Waco to Houston and Galveston. Except for the branch strip most of the counties are in the black soil belt. Nearly one-half the 254 counties have a population averaging less than ten inhabitants per square mile, the most thinly settled areas being the Edwards plateau and Trans-Pecos region.



GRAPH OF GROWTH OF TEXAS POPULATION, SHOWING PERCENTAGE OF NEGRO ELEMENT

The population is predominantly native-born white of Anglo-Saxon extraction. The larger portion came originally from Tennessee, Alabama, Georgia, Mississippi and other States of the older South, with, however, especially in recent years, an appreciable addition from the Middle Western States. Despite the large preponderance of native whites, Texas has received more emigrants from foreign countries than any other Southern State. In 1920 there were 360,519 foreign-born in Texas, or 7·7% of the total population. In addition there were 276,670 persons born of foreign parentage and 168,714 born of mixed parentage. These three classes together, representing a classification known to the Census Bureau as "foreign white stock," comprised 17·3% of the total population of Texas and 20·8% of the white population. Of the foreign-born over one-half, and of the "foreign white stock" nearly one-half were Mexicans. There were 249,652 born in Mexico and 398,174 of "foreign Mexican stock."

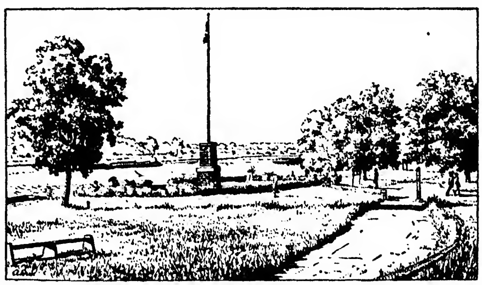
These immigrants have crossed the Rio Grande primarily in response to a demand for labour on the ranches and farms of southern and south-west Texas. The Federal immigration restrictions apply to them, but restrictions are lifted for the temporary immigration of Mexican labourers to satisfy certain seasonal demands. Besides the great length of the Mexican border prohibits an adequate guard to prevent unlawful access to the country. Most of the present Mexican population is along the Rio Grande and in south Texas, but throughout the cotton belt there is an appreciable scattering. Germans and Austrians were next in importance. There were 31,062 foreign-born Germans and 159,219 of German stock, 6,441 foreign-born Austrians and 64,074 of Austrian stock; 12,819 born in Czechoslovakia, 7,057 in Russia; 5,047 in Poland; 8,024 in Italy; 7,685 in England; 4,333 in Ireland; 4,536 in Sweden and 4,175 in Canada. Most of the German and Austrian inhabitants are found in south-central Texas where they constitute a thrifty element of the agricultural population. The negro population of Texas in 1920 was 741,695, or 15·9% of the whole. The negro has increased in number since 1900 but not in proportion to the increase in total population. The negro migration from the South to Texas is not large, the migration being rather to the Northern States. The negroes are almost all in the eastern half of the State, principally along the eastern border, the Gulf coast and in the cities. In 1920 518,321 negroes were rural dwellers and 223,373 lived in cities, the city element showing the greatest increase between 1910–20.

The total urban population in 1920 was 1,512,689, or 32·4% of the whole, as compared with 24·1% in 1910 and 17·1% in 1900. The chief cities with their 1920 population (Census Bureau 1927 estimate in parentheses) were: San Antonio, 161,379 (211,400); Dallas, 158,976 (211,600); Houston, 138,276 (no estimate made because of exceptional growth); Fort Worth 111,-336 (163,600); El Paso, 77,560 (113,500); Galveston, 44,255 (49,900); Beaumont, 40,422 (54,400); Wichita Falls, 40,079 (no estimate made, exceptional growth); Waco, 38,500 (45,700); Austin, 34,876 (38,800). Other cities with a population over 10,000 in 1920 were Abilene, Amarillo, Brownsville, Cleburne, Corpus Christi, Corsicana, Del Rio, Denison, Greenville, Laredo, Marshall, Palestine, Paris, Port Arthur, Ranger, San Angelo, Sherman, Temple, Texarkana and Tyler.

Government.—The State's fourth constitution adopted in 1876 remains the basis of the government. Since its adoption there had been (1927) 58 amendments, the majority of them involving but minor points. An amendment may be proposed by a two-thirds vote of all members elected to each house of the legislature, and is adopted if approved by a majority of the voters at the next election.

The legislature is composed of a senate of 31 members, chosen by popular vote for four-year terms, one-half the body retiring every two years, and a house of representatives of 150 members (the constitutional maximum) elected biennially. Bills may originate in either house, except bills of revenue, which must originate in the house of representatives, but can be amended or rejected as other bills in the senate. Regular meetings of the legislature are biennial, opening upon the second Tuesday of January in odd-numbered years. Special sessions may be called by the governor.

The chief executive and administrative officers are a governor, lieutenant-governor, secretary of State, comptroller of public accounts, treasurer, commissioner of the general land office, attorney-general, railroad commissioners (three), commissioner of agriculture, and superintendent of public education. All are elected by the voters except the secretary of State who, contrary to the custom in most States, is appointed by the governor.



BY COURTESY OF HOUSTON CHAMBER OF COMMERCE
SAN JACINTO BATTLEGROUND NEAR HOUSTON. CLOSE TO THE SPOT WHERE GENERAL HOUSTON RECEIVED THE CAPTURED MEXICAN GENERAL SANTA ANNA, IN 1836, DURING THE STRUGGLE FOR TEXAN INDEPENDENCE

All serve for two-year terms except the railroad commissioners who serve for six years. The governor's powers are rather more extensive than those of the average State executive. The actual administration of the details of government is performed by many officials, boards and commissions mostly appointed by the governor so as to be under executive control.

The State judiciary consists of a supreme court, a court of criminal appeals, 11 courts of civil appeals in 11 districts and over 100 district courts. These are State courts, all provided for by revenue from the State's general fund. The 11 civil appellate courts,

the court of criminal appeals and the supreme court all consist of three justices each, elected for six-year terms. In addition the supreme court has an assisting commission of appeals consisting of two sections of three judges each, and the court of criminal appeals has an assisting commission of two members. These commissions are temporary bodies. The district courts each have one judge elected for four years. Minor criminal and civil cases are tried by a justice of the peace or in the county court.

Finance.—In 1922, according to the estimate of the Federal Census Bureau, the total wealth of Texas was $9,850,000,000. In 1928 a conservative estimate is approximately $12,000,000,000. The principal developments between 1922–28 which increased the total wealth were the great increase in the output of petroleum, increased manufacturing, an increase in power transmission lines, new reclamation and irrigation projects, and an increase in property values, especially in the cities The income of Texas from raw products (crops, live stock products, minerals, forest products) was approximately $1,385,000,000 in 1928. To this may be added approximately $325,000,000 which represents the value added to raw products by manufacturing processes in the State. The total of $1,710,000,000 annual income takes no account of the wholesale or retail trade, professional income or other sources of wealth.

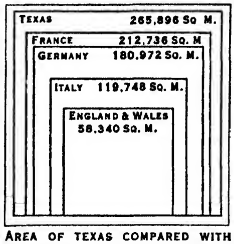
The assessed valuation of property in the State amounted to $3,898,954,064 in 1927. State receipts from taxation for the fiscal year ending Aug. 31, 1928 were $70,968,300. Of this $23,822,261 was a direct *ad valorem* tax on property. A poll tax of $1.50 from each person from the ages of 21 to 60 amounted to $1,737,616 for the year ending Aug 21, 1928, and an occupation tax which contributed $306,677 From a gross receipts tax $8,336,278 was received Three-fourths of this is credited to the general revenue and one-fourth to the available school fund. The inheritance tax for the same year amounted to $978,937, all of which was credited to the general revenue fund A sixth tax is a gasolene sales tax, one-fourth of which goes to the available school fund and three-fourths to the highway fund This amounted for the year ending Aug 31, 1928 to $19,214,075 An auto licence fee amounted to $14,559,566 the same year, all of which was credited to the highway fund The final tax source is the franchise taxes collected by the secretary of State and paid into the general revenue fund These in the same year amounted to $2,012,886

In addition the State receives annually many millions of dollars from sources other than taxes, the exact amount for the year ending Aug. 31, 1928 being $18,870,024 These are fees collected by the various departments, interest on the various permanent funds, revenue from the State prison, etc A substantial amount also comes from the U S Government for highway purposes. The grand total of receipts of the State Government for the year ending Aug. 31, 1928 was $89,838,324

Total disbursements for the same year amounted to $84,358,918. Of this amount $22,602,419 was expended from the general revenue fund, $20,551,172 from the available school fund, and $28,762,188 from the highway fund The remaining $9,557,619 was expended from the miscellaneous smaller funds numbering about thirty-seven. The bonded debt in 1926 was but $4,002,200, a small total for so large a State, amounting to an average of but $.75 per caput All of it is owned and held by the permanent funds of the public schools and State institutions for which it was incurred. There were on Oct. 3, 1928 636 national banks and 729 State banks Resources and liabilities of the national banks totalled $1,189,295,000; of the State banks, $327,663,101

Education.—The school population of Texas—7 to 18 years inclusive—was 1,399,798 for the year 1928–29. Education in the public schools is free for all children above six years of age Between the ages of 7 and 16 attendance at some school, either public or private, is compulsory. The public school system in 1928 was organized into approximately 1,000 independent school districts and 7,200 common school districts. There were in attendance during the year 1925–26, 455,493 white pupils and 89,143 coloured pupils in the independent districts, and 374,771 white pupils and 96,553 coloured pupils in the common districts, in all an elementary school attendance of 1,016,260 In addition there were 181,127 white and 13,067 coloured high school students. The value of all public school buildings, grounds and equipment in 1928 was $179,200,598.

The most pressing problem of the school system is the proper maintenance of the common or rural schools. The situation is recognized and aided by a special rural aid appropriation from the State amounting to $1,500,000 for 1926–27 and $1,600,000 for 1927–28. The regular State appropriations for 1927–28 were $20,549,220. Local taxation for public school maintenance totalled $22,951,676. The totals for State and local support show that the State shared the educational expense almost fifty-fifty with local units, a proportion which is very high indeed compared with other States. Texas has a larger permanent endowment for its public schools than any other State, the fund totalling $76,445,248 in 1926 It was derived from the sale of public school lands and is invested chiefly in Government bonds



AREA OF TEXAS COMPARED WITH CERTAIN COUNTRIES OF EUROPE

There are 17 State-supported institutions of higher learning. The chief is the University of Texas at Austin and its branches, the Medical school at Galveston, and the College of Mines and Metallurgy at El Paso. The Agricultural and Mechanical college is located at College Station, the North Texas Junior Agricultural college at Arlington, and the John Tarleton Agricultural college at Stephenville The Texas Technological college is at Lubbock, and the College of Industrial Arts at Denton. Prairie View State Normal and Industrial college for negroes is at Prairie View State Teachers' colleges are located at Alpine, Canyon, Commerce, Denton, Huntsville, Kingsville, Nacogdoches and San Marcos

Charities and Corrections.—There are under the administration of the State board of control the following charitable and correctional institutions, their average populations in 1927 being given in parentheses: Five hospitals for the insane at Austin (2,063), Rusk (915), Terrell (1,725), Wichita Falls (544) and San Antonio (2,351); a special State hospital for epileptics at Abilene (791); State tuberculosis sanatorium at Carlsbad (362); State orphan home at Corsicana (584); home for dependent and neglected children at Waco (97); State juvenile training school at Gatesville (1,071); Girls' training school at Gainesville (159), school for the blind at Austin (238); school for the deaf at Austin (503); deaf, dumb and blind institute for coloured youths at Austin (180); Confederate woman's home at Austin (97), Texas Confederate home at Austin (353), and the Austin State school for the feeble-minded at Austin (453). The State prison is situated at Huntsville, and there are also 12 State convict farms

Mines and Quarries.—The value of the total mineral output of Texas leaped from $29,220,000 for 1915 to $371,250,000 for 1920. A sudden depression reduced the value of the 1921 output to $212,302,000, but from then to 1928 the valuation steadily increased, amounting to $351,211,000 for 1925 and $435,000,000 for 1928 The peak valuation of 1920 was due primarily to inflated prices, particularly of petroleum, but the increases since 1921 were due primarily to increase in volume of output, that of 1926 being greater than for any previous year. The 1925 valuation represented 7 05% of the mineral output of the United States, Texas ranking fourth among the States as a producer

In 1925 all except $89,211,000 and in 1926 all except $61,300,000 of the total valuation was contributed by the petroleum industry, Texas ranking third as an oil-producing State in both years. In 1928 the State rose to first place The year 1928, with an output of 255,557,000 bbl., was the 18th successive year in which there had been a substantial increase in petroleum production in the State. These outputs may be compared with that as late as 1918 which was only 38,750,000 bbl., from which some idea of petroleum developments in Texas since the World War may be had. The value of the petroleum output increased from

$193,580,000 for 1923 to $308,700,000 for 1926. Next to cotton, petroleum has become the State's chief money-making product.

The petroleum-producing fields are widely scattered and differ greatly in character. It was the discovery of the Spindle Top field near Beaumont in 1901 that first brought Texas to the front in petroleum production. This field in 1902 produced 17,420,949 bbl. after which it declined so that in 1925 it produced but 428,-873 barrels. In 1926, however, there came a startling leap to 13,370,000 bbl., the field again leading all Texas fields but one. Another even older field, the Corsicana, in which production started in 1896 saw a similar rejuvenation in 1923 when deeper sands were discovered, the output jumping from 245,705 bbl. in 1922 to 32,361,150 bbl. in 1923. The field in Wichita and Wilbarger counties was first in 1926 with 15,249,000 barrels. There were in all 35 producing fields.

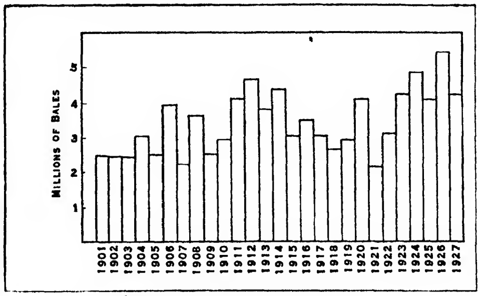
Next to petroleum the two most important mineral products were natural gas gasolene and natural gas. Production of the former increased in value from $14,460,000 in 1924 to $18,346,000 in 1927. There were 117 natural gas gasolene plants in 1925. Production of natural gas increased in value from $13,748,000 in 1924 to $19,715,000 in 1925, Texas ranking fifth among the States both years. One of the most remarkable industrial developments of Texas in 1927 was the rapid extension of gas pipe lines into new territory. Principal gas production is from the great field north of Amarillo, from Palo Pinto, Clay and Eastland counties in North Central Texas and from Harrison county in East Texas.

There were six active cement plants in 1925 producing cement to the value of $8,729,046, giving this fourth place among the minerals. Clay products were valued at $6,298,045. Clays susceptible of commercial development have been found in nearly every county of the State and in great variety, including several grades of brick clay, pottery, tile and statuary clays. There were 53 operating clay-products plants in 1923. Clay deposits, cement materials, sand and gravel and building stone seem apparently inexhaustible and merely await better transportation facilities and increased local demand for their increased development. The increase in highway and other construction has brought about greater demand for sand and gravel, the 1925 output being valued at $3,478,517. Stone products in 1925 were valued at $2,076,-560. Limestone is used extensively in the making of cement, but is also quarried for building stone and burned in kilns for the making of lime. The 1926 production of limestone was valued at $2,210,828, and the output of lime at $706,153. There is a large industry in Texas manufacturing plaster, wall board, cement, roofing and other materials from gypsum. The State ranked fourth in point of output and fifth in point of value of gypsum in 1925, the value being $3,721,954. The asphalt production in 1925 was valued at $4,900,000, 204,527 tons being native, and 220,473 being manufactured from petroleum. With the closing of the Louisiana sulphur mines in 1924 Texas in 1925 remained the only large sulphur-producing State in the Union, producing 99·9% of the nation's total. The output in 1925 was 1,409,262 tons valued approximately at $11,000,000.

The abundant supply of petroleum and natural gas for fuel has retarded the development of coal deposits. Texas has a fair supply of bituminous coal which is found in north-central and middle-western Texas and also of sub-bituminous or cannel coal found in Webb and Maverick counties in south-west Texas along the Rio Grande. In addition there is an almost inexhaustible supply of lignite, the belt extending across the State from the vicinity of Laredo on the Rio Grande to north-east Texas, covering about 60,000 sq.m. and having an estimated quantity of 30,000,000,000 tons unmined. The bituminous and sub-bituminous areas cover about 25,000 sq.m. and contain, it is estimated, 8,000,000,000 tons. Coal produced in 1926 totalled 1,091,158 tons valued at $1,751,000.

The chief metal of commercial importance in 1924–25 was silver, the output being valued at $482,895 and $383,088 respectively. Silver ores are found in Culberson, Hudspeth and Presidio counties in the Trans-Pecos province. There is a steady production of mercury, Texas producing about one-fourth of the annual production of the United States. There are extensive iron deposits easily available, but production is slight chiefly because of lack of coking coal. Manganese, zinc and tin ores are found, but are only slightly developed.

Agriculture and Live Stock.—Texas is preëminently an agricultural State. In 1927, for the eighth successive year, it led all other States in the value of crops raised. In number of live stock, according to the Federal farm census of 1925, it was ex-



COTTON CROP EACH YEAR, 1901–1927
The figures are running bales, counting round as half bales

ceeded by none, and in value of live stock it was exceeded only by Iowa. Of its total population 2,114,532 or 40·6% lived on farms in 1925. Of its total land area, estimated at 167,934,720 ac., 109,674,000 ac. were owned as farm lands in 1925, and 29,-309,000 ac. of this was classified as crop land. By 1927 crop land had increased to approximately 32,000,000 acres. Of the 75,068,-000 ac. classified as pasture, 13,617,000 ac. was ploughable, 11,-230,000 ac. was woodland and the remainder chiefly treeless hills and plains used for grazing purposes. The number of farms increased from 436,033 in 1920 to 465,646 in 1925, and their average size decreased from 261·5 to 235·5 acres.

The period 1920-25 was a difficult one for agriculture, however, because of the sharp depression of prices which occurred in 1921 and continued for several years thereafter. The total value of all farm property, which between 1910-20 had increased from $2,-218,645,000 to $4,447,420,000, fell to $3,471,867,000 by 1925. Between 1920–25 farm land decreased $620,520,000 in value, farm buildings decreased $34,851,000, farm implements and machinery decreased $12,422,000 and farm live stock decreased $308,-328,000. The decrease in value of land per acre was from an average of $28.46 to $23.94. The decrease in live stock values was considerably over half, the total valuation of live stock in 1925 being but $284,698,000.

The years 1926–28 witnessed a rapid revival of prosperity in the live stock industry, but low yields and, to a lesser extent, low prices for some products, prevented a corresponding increase in crop values. The following table shows the comparative number and value of live stock in 1925 and 1928:—

	Number 1925	Number 1928	Value 1925	Value 1928
Cattle	6,275,000	5,607,000	137,422,500	224,840,700
Swine	1,250,000	1,375,000	12,500,000	16,500,000
Sheep	3,500,000	4,593,000	26,250,000	39,040,000
Horses	857,000	748,000	46,278,000	33,660,000
Mules	1,042,000	1,000,000	86,486,000	70,000,000

Texas led all States in 1928 in the number of cattle, sheep and mules. There were also in 1927, 2,400,000 goats in Texas, valued at $11,500,000. Texas had more than one-half the total number in the United States.

Texas is ideally adapted to live stock raising. There are large areas which produce luxuriant pasture grasses, and the soil readily produces feed-stuffs such as corn, Kafirs, oats, hay, etc. The mild winters and light snows make it unnecessary to provide expensive sheltering, or store great quantities of winter feed. Beef cattle are raised primarily in the western and southern areas of the State, while dairying is developing rapidly in north-central Texas where a denser population provides good local

markets. There were 936,000 milch cows in 1928. Butter made in creameries increased from 4,982,000 lb. in 1918 to 14,594,000 lb. in 1926 The total value of dairy products for 1925 amounted to $35,442,000. Large-scale ranching, so prevalent formerly on the Great Plains area of north-western Texas, is fast disappearing in that region, giving way largely to crop growing. Below the cap rock throughout the great expanse of middle west and north-central Texas there remains a large ranching industry, with the large ranch holding its own, particularly in the rougher country. The chief "big ranch" country, however, may be said to begin with Kennedy county on the coast below Corpus Christi and spread toward Laredo and San Antonio, continuing on across the broad expanse of the Edwards plateau, including the middle and upper sections of the Rio Grande valley and the Trans-Pecos province.

The sheep and goat industry is much more highly localized, being confined largely to the Edwards plateau and the hilly regions of west-central Texas. Wool production in 1927 was 32,675,000 lb, valued at $10,357,975 The weight per fleece averaged 8 5 lb as against 7·7 lb for the entire United States The Angora goat with its production of fine mohair has been bred up from the common black goat introduced into Texas by the early Mexicans by importing Angora rams. The value of mohair produced in 1926 amounted to $4,550,000.

Swine decreased from 3,205,000 in 1910 to 2,400,000 in 1920 and 1,250,000 in 1925, despite the fact that they are favourably advocated by agricultural specialists for Texas farmers. Their raising is largely an avocation of the cotton growers in the eastern part of the State. Higher prices for cotton and successive shortages in the corn crop are the main reasons for their decrease. On the other hand when cotton prices were poor in 1926–27 swine showed their first increase in numbers for many years. Poultry-raising showed an encouraging increase between 1920–25. Eggs produced and chickens raised in 1924 were valued at $33,000,000. In addition the total value of turkeys marketed and consumed locally was estimated at about $14,000,000.

The annual value of all crops in Texas ranged, for the period 1919–27, from $424,776,000 for 1921 to $1,071,527,000 for 1919 In 1926 the total value was $631,584,000; in 1927, $729,754,000. Of the 1927 total value, $464,053,000 was contributed by the cotton crop alone, Texas leading all States and raising slightly more than one-third of the cotton crop of the United States. For many years there was a feeling that the cotton-raising area would be halted at the foot of the cap rock which marks the beginning of the high plains of Texas, but the phenomenal development of cotton-raising above the cap rock between 1920–27 has demonstrated that there is yet much land that can be turned to that use. Of a total farm acreage of about 31,000,000 ac. in 1926, 18,363,000 ac. were devoted to cotton This was the largest acreage up to that date, and the resulting crop of 5,628,000 bales was the largest ever produced in the State. Prices were very low, however, and the return of $395,653,000 from the crop was lower than in any year since 1921. As a result only 16,270,000 ac. were planted to cotton in 1927, yielding but 4,280,000, but valued, because of higher prices, $68,500,000 above that of 1926. Of the agricultural population it is estimated that at least 1,750,000 derive their livelihood largely from cotton-growing.

The value of other crops in 1927 follows: corn $64,118,000; winter wheat, $39,355,000; grain sorghums, $39,242,000; oats, $31,793,000; tame hay, $14,880,000, sweet-potatoes, $8,128,000; rice, $6,756,000; barley, $4,081,000; white potatoes, $3,885,000; wild hay, $2,770,000; sorghum-syrup, $2,584,000; sugar-cane syrup, $2,224,000 Wheat and rice are grown for the market and all other grains are primarily for home consumption. Corn is grown throughout the crop-growing areas of the State. Rice is confined to the lower courses of the rivers on the coastal plain. The other grains are principally in the northern and western sections. There has been a notable increase in the acreage devoted to barley from 25,000 in 1919 to 195,000 in 1927, but it is confined almost entirely to the northern Panhandle. This is also the chief wheat belt. In the extreme southern portion of Texas there is a rapidly developing production of sub-tropical fruits and vegetables. There is little canning, as yet, most of the vegetables being shipped for table stock, the early spring permitting them to be marketed at high prices. Texas is not a leading fruit-growing State, but approximately $5,000,000 annually is derived from orchard crops Citrus fruits, especially oranges and grapefruit are grown along the Gulf coast and in the lower Rio Grande valley, the output being 360,000 boxes in 1926 as compared with 71,000 in 1923.

Forest Products.—In 1925 Texas ranked eighth among the States in lumber production. Between 1922–27 production varied between 1,500,000,000 and 1,600,000,000 bd.ft. annually and the annual value of output was between $50,000,000 and $55,000,000. In addition to the regular lumber cut an additional 400,000,000 ft. was annually taken for railway ties, telephone and telegraph poles, fence posts, etc. The commercial lumber output comes almost entirely from the heavier forested areas in the eastern 25 or 30 counties. About 90%—1,351,248,000 bd.ft. in 1925—is yellow pine The only other soft wood of importance was cypress, of which the 1925 cut was 15,079,000 board feet. About 200,000,000 bd.ft. of hardwood lumber is cut annually, the chief varieties being oak (98,486,000 bd.ft. in 1925) and tupelo (16,422,000 bd ft. in 1925). There is some turpentine and rosin production from the long-leaf pine section in the south-east. The rate of cut in Texas, 1922–27, was very heavy compared with the total timber resources of the State. Surveys estimated about 17,000,000,000 bd.ft. of pine and about 7,500,000,000 bd ft of hardwood still standing in 1927. The area of virgin pine was but 1,100,000 ac. compared with an original area of 14,000,000 acres. There are no national forests in the State, and State action toward conservation was slow in commencing, the first purchase of tracts for reforestation taking place in 1923.

Manufactures.—The products of Texas factories increased in value from $969,556,000 in 1923 to $1,237,952,000 in 1925 The value actually added by the various manufacturing processes was $329,246,334 respectively. In 1925 there were 3,606 establishments employing an average of 106,792 wage-earners and paying $116,363,302 in wages. The industries are almost entirely those which use as raw material the mineral, agricultural and forest products of the State. The advantages of Texas for manufacturing are that an abundance of raw materials exists at hand, petroleum, natural gas and coal furnish cheap and unlimited fuel, and living costs are low Lack of capital has been the chief deterrent The leading industries in 1925 follow:—

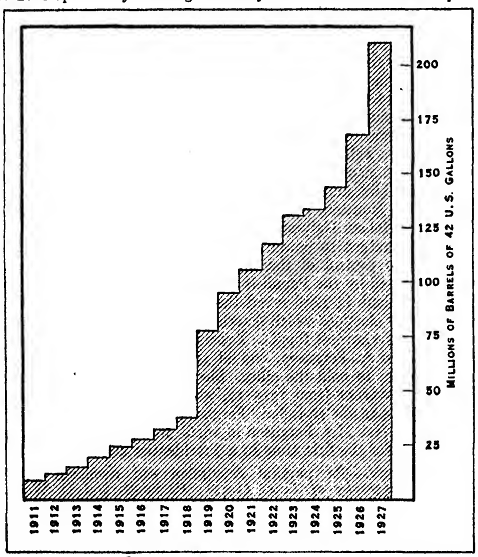
Industry	Establishments	Wage-earners	Value of products
Petroleum-refining	63	10,902	$488,181,732
Cottonseed oil, cake and meal	167	3,924	86,387,983
Slaughtering and meat-packing products	27	3,805	79,208,777
Lumber and timber products of sawmills and planing mills	300	20,644	60,675,779
Flour, feed and other grain-mill products	90	1,212	54,528,293
Car and general construction and repairs of steam railway shops	109	14,692	43,612,493

Manufacturing cities of the first class were Dallas, Houston, Fort Worth and San Antonio. Those of the second class were El Paso, Texarkana, Beaumont and Galveston.

Commerce and Transportation.—Texas ranked as the chief exporting State in the Union in 1924, and in 1925 and 1926 ranked second only to New York. The value of the exports these three years was respectively $737,216,502, $758,665,052 and $648,991,954. Of the total, approximately two-thirds ($429,388,673 in 1926) consists of raw cotton. It was the low price of this commodity in 1926 that brought the total value of exports down, the actual tonnage having increased. Other products exported in large quantities, in the order of their value, were wheat, gasolene, illuminating oil, gas and fuel oil, lubricating oil, sulphur, cottonseed cake and meal, wheat flour, machinery and parts, chemicals, lumber, wood and paper and vegetable food products. Imports were much less important, amounting in 1926 to about $49,000,000, and consisted largely of manufactured articles for distribution on the south-western market. In addition to the foreign trade, to which the statistics above apply, there is a heavy coastwise trade

between Texas ports and ports of the Atlantic seaboard. Total tonnage of coastwise trade varies from 15,000,000 to 20,000,000 annually and is valued at about $600,000,000. The interior harbours of the Texas coast line offer excellent advantages once the outlying bars are penetrated. It is usually necessary to dredge through the bars and often in the harbours themselves to make them deep enough for ocean vessels. Galveston is the oldest and the chief port. Its dock and terminal facilities are well built up. The total commerce of the port in 1926 was 6,203,835 tons valued at $688,433,560. The port of Houston has shown more rapid development than any other in recent years. It is situated about 60 m. from the Gulf but is served by the Houston ship canal, large enough for ocean vessels. In 1926 1,391 seagoing vessels arrived and 1,386 departed, the total commerce of the port amounting to $400,116,647. Corpus Christi is the latest addition to the deep water ports of Texas, the year 1927 witnessing the first heavy traffic since the completion of a channel through Corpus Christi bay and Aransas pass to the Gulf. It is the chief port for all of southern Texas. The other important ports are Texas City, Port Arthur, Beaumont, Orange and Freeport. There is some trade across the Mexican border, principally at Brownsville, Laredo, Eagle Pass, Presidio and El Paso.

There were 16,287 m. of main line railway track in Texas at the opening of the year 1928. From 1915 to 1924 there was almost no construction, due first to the World War and afterwards to the general depression which prevailed in all industries. From 1925 to the end of 1928 there was considerable construction amounting to over 100 m. annually, more than in any other State. A part of the construction was into new oil-fields, especially north of Amarillo, but the greater part was but a carrying on of programmes of development by the larger railways which had been interrupted



PETROLEUM PRODUCTION, 1911–1927

by the World War. Most of the construction was in the northern Panhandle, in the region bordering New Mexico, in the Trans-Pecos province and in the lower valley of the Rio Grande.

There were, in 1927, approximately 180,000 m. of public roads in Texas, of which 18,728 m. were in the State highway system. At the close of 1927 9,643 m. of the State system were surfaced, about 800 m. being paved and 4,487 m. being gravelled or macadamized. Receipts to the State highway department for 1927 totalled $25,976,165, coming chiefly from licence fees, gasolene taxes and Federal aid, and disbursements totalled $20,115,964. From 1925 to 1927 motor bus transportation developed rapidly, and in 1927 buses were operating regularly over about 21,000 m. of Texas highway. There were in Sept. 1927, 247 companies operating 865 passenger vehicles. Motor vehicle registration in the State increased from 194,720 in 1917 to 1,121,233 in 1927.

HISTORY

The earliest explorations were made by the Spaniards, Cabeza de Vaca, 1528–36, and Francisco Vásquez de Coronado 1540–42. There were many other Spanish expeditions in the first three-quarters of the 17th century which entered or crossed parts of the State, and in 1682 the Spaniards founded the first permanent settlement at Isleta in the Rio Grande valley a few miles below El Paso. In 1685 the French under the Sieur de la Salle founded a colony at Matagorda bay, which, however, was soon abandoned. The French threat was sufficient to scare the Spanish into activity, and beginning in 1690 they established several ecclesiastical, military and civil settlements known respectively as missions (Franciscan), presidios and pueblos. In 1727 the territory, with vaguely defined limits, was formed into a province and named Tejas, or Texas, after the confederacy of Tejas Indians. For more than a century the conditions were favourable for colonization. The French in Louisiana proved peaceable neighbours and that province both under French (to 1763) and under Spanish rule (1763–1803) served as a protection against the English. Spain failed to take advantage of this favourable period, however, and it was lost after the United States purchased Louisiana in 1803.

Three abortive Anglo-American invasions during the first few years of the century indicated the future trend of events. The first, under Philip Nolan, in 1799–1801, was poorly supported, and was crushed without difficulty; the second, under Bernardo Gutiérrez and Augustus Magee, 1812–13, captured San Antonio and defeated several Mexican armies, but was finally overpowered; the third, under James Long, 1819–21, was less formidable. The United States claimed the eastern part of Texas, basing the claim on the Louisiana Purchase, but by the Treaty of Florida with Spain, finally ratified in 1821, these claims were given up and the eastern and northern boundaries were fixed as follows: the Sabine river, the 94th meridian (approximately), the Red river, the 100th meridian, the Arkansas river and the 42nd parallel. So far as Spain was concerned this was only a form, inasmuch as Mexico, of which Texas was a part, was just completing its long struggle for independence (1810–21). In 1821, also, Stephen F. Austin established the first permanent Anglo-American settlement at San Felipe de Austin on the Brazos river. This was followed by extensive immigration from the United States during the period of Mexican rule. It is estimated that the population, exclusive of Indians, increased from 4,000 in 1821 to 10,000 in 1827, and nearly 20,000 in 1830. In 1827 Texas was joined to Coahuila to form a State of the Mexican federation.

Difficulties arose between the Americans, especially the members of the Edwards colony around Nacogdoches, and the Spanish settlers who were there before the Americans came. There was also a Federal decree in 1830 forbidding further immigration into the colony, while lavish grants of land were made to Mexican favourites. A convention at San Felipe de Austin in 1835 organized a provisional government with Henry Smith, who desired independence, as governor and Sam Houston as major-general of the armies of Texas, and two commissioners were elected to seek aid in the United States. Hostilities had already begun, armed conflicts having taken place at Velasco, Anahuac and Gonzales over customs regulations and attempts of the Mexicans to disarm the American settlers.

A Mexican army under General Cos, which had marched into Texas to disarm the Texans, was driven out of San Antonio, but early in 1836 Santa Anna with a larger army returned to lay siege to the city. On March 6, the Alamo, in which the garrison of 183 defenders had taken refuge, fell with the slaughter of every man. On the 20th, the Mexicans captured the Texas general, Fannin, and his force of 371 men, and a week later shot them all except 20 that had escaped. Houston then assumed active command and retreated before Santa Anna until he reached the San Jacinto river,

where he turned and dealt the Mexicans a crushing blow which brought the war to an end. Santa Anna himself was captured. The weakness of the Mexican Liberals and the necessity of securing aid in the States led the Austin party to abandon their opposition to independence, and on March 2, a convention had assembled at the town of Washington and adopted a declaration of independence. On the 17th a republican Constitution was adopted, and in Sept. 1836 Houston was elected the first president. In 1837 the independence of the republic was recognized by the United States, Great Britain, France and Belgium

Standing alone the republic faced many difficulties Mexico had by no means accepted the independence declaration and threatened continual hostilities. There were troubles with the various Indian tribes. The public debt mounted and the Texas paper dollar fell in value to about 2 cents. It was generally admitted that the United States desired to annex Texas, but the question was bound up with that of slavery over which the Union was divided In March 1845 Congress passed a joint resolution offering Statehood to Texas, and this the Texans gladly accepted The United States was to settle all questions of boundaries with foreign countries, while Texas was to retain all its vacant and unappropriated public lands. The formal admission occurred in Dec. 1845 Texas had claimed the Rio Grande to its source as its western boundary, although as a political division of Mexico its limits had never extended farther west than the Nueces and the Medina The United States asserted the Rio Grande claim and prepared to defend it, at the same time the Mexican Government considered the annexation, regardless of the boundary question, a declaration of war by the United States. In the Treaty of Guadalupe Hidalgo (1848) which ended the war Mexico accepted the Rio Grande boundary Texas also included then the eastern half of present New Mexico (that portion east of the Rio Grande) and Colorado, a corner of Wyoming (the boundary running north from the source of the Rio Grande to the 42 parallel), south-western Kansas and the arm of Oklahoma north of the Panhandle. By the Compromise of 1850 all of this territory not included in Texas to-day was ceded to the United States for $10,000,000.

Texas was a slave State from the first Its climate and soils, especially in the section first settled, made its industries similar to those of the older Southern States, while most of its settlers were natives of the slave States east of the Mississippi A strong Unionist influence was exerted by the considerable German element which had settled in the State from 1845–60, but neither this nor the influence of Sam Houston, then governor, could prevent a convention which met at Austin, Jan 28, 1861, from drawing up and adopting articles of secession. Houston was deposed and the lieutenant-governor, a secessionist, held office in his place. The State, luckily, was not the scene of active military operations during the Civil War, although it is interesting to note that the last battle of the conflict was fought on its soil at Palmito, near Palo Alto, on May 13, 1865, more than a month after the surrender of Appomattox In conformity with President Johnson's plan of reconstruction, a Constitution recognizing the abolition of slavery, renouncing the right of secession and repudiating the war debt was adopted in 1866 and a Unionist Democrat was elected governor. When in 1867, the congressional plan of reconstruction was substituted, Texas was joined to Louisiana to constitute the fifth military district, and Gen. P. H. Sheridan was placed in command. A new Constitution was adopted in 1869. In Feb. 1870, the legislature ratified the 14th and 15th Amendments to the Federal Constitution, and in March it was readmitted to the Union. But the State remained under the rule of negroes and carpet-baggers, supported by U.S troops, until the inauguration of Governor Coke in 1874. A legislature responsive to the people had also been elected, so that the people were again in control. The Constitution of 1869 containing many obnoxious provisions was replaced by the present Constitution adopted in 1876.

After 1876 there was rapid recovery from the effects of the war and reconstruction, and the history of the State becomes chiefly a record of agricultural and industrial expansion. Cotton production, which in 1859 amounted to 431,645 bales, slumped heavily during the Civil War and it was 1870 before production again reached the 400,000 mark. In 1878 it went above 1,000,000 bales for the first time. In 1891 it first passed 2,000,000 bales and in 1894 it passed 3,000,000 bales. The early cotton production all came from the heavily wooded sections of eastern Texas, and expansion was not rapid until the settlement of the black land belt, which coincided with the extension of railways into the area in the early '70s. The second great impetus was given by the settlement of the fertile prairie lands of middle-west Texas which began in the early '90s After the Indians were driven from southern and western Texas, the herds of wild cattle began to increase rapidly so that, after the Civil War, they crowded the ranges. A good market in the Middle West inaugurated the practice of rounding up these cattle and driving them north over cattle trails that soon became well-defined. The trail-driving era continued until the middle '80s when the extended railways began to intercept the drive. During the years of reconstruction, much violence and disorder became prevalent, and on the frontier where there was almost no protection, this condition was not checked. Organized gangs of land and cattle thieves often controlled whole neighbourhoods and worked their will. Furthermore the Indians were restless and menacing. The situation was met by the organization, in 1874, of the famous Texas Rangers, a State constabulary force, which succeeded soon in controlling the situation.

Another troublesome matter was the strife between ranchman and settler, or "nester," which found vent largely in the cutting of the barbed-wire fences which were beginning to spread over the plains. A special session of the legislature was called to deal with this problem in 1884 and drastic legislation to stop the practice was enacted With the extension of the railways there developed also widespread abuses in their operation, especially various forms of discrimination The demand for their control culminated in the hotly contested political battle of 1892 which the radicals won The victory resulted in the establishment of a railway commission to fix the rates and investigate complaints In 1899 and in 1902 there were destructive floods on the Brazos river, which led to the building of levees to protect the lands from overflows In 1900 a great tropical hurricane swept the coast country of Texas, doing tremendous damage, especially at Galveston. The loss of life was estimated at 6,000 The result was the building of the Galveston sea wall. Out of the disaster, also, the commission form of city government was born, it proving the most trustworthy and efficient in Galveston in the heavy task of reconstruction Other Texas cities, Houston, Fort Worth, Waco and Austin, were among the first to follow Galveston's example

Since its return to power in 1874 the Democratic Party has continued in control of the State Government. Its supremacy was threatened by the Populists in 1894, but the adoption of the free silver plank in 1896 saved the situation for the Democrats The primary elections which determine the Democratic candidate are usually the hardest fought Texas in 1924 elected as governor, Mrs. Miriam A Ferguson, one of the two first women in the United States to hold the office. She was the wife of James E Ferguson, governor from 1915–17, who was impeached Opposition in Texas to the so-called "Ferguson régime" mobilized sufficiently to defeat Mrs Ferguson in 1926 In 1928 the State voted Republican for the first time in a Presidential campaign.

TEXTILE PRINTING. The application of art and science in the production of designs on any fibrous materials without resource to embroidering or appliqueing. (*See* CALICO PRINTING.) Its origin is unknown. Some ascribe it to the Chinese, but it is more likely that India and Egypt could claim earlier knowledge of the printing of textiles. Indian prints were highly valued by the Romans, and India is undoubtedly the source from which the application of block printing to woven fabrics spread by way of Persia, Asia Minor and the Levant to Europe. Although wood engraving was used in Europe for illustrating books as early as the 15th century, it was not until the latter half of the 17th century that textile printing was practiced to any great extent. About that time the French brought from the east coast of India, blue and white resist prints and particulars of the methods used to produce them. At the end of the 17th century Augsburg was noted for its printed linens, and in 1746 the works of C. Koechlin was founded at Mulhouse. Textile printing was established in England in 1690 by a French refugee who opened a works near Richmond, but little progress was made until 1764 when Messrs. Clayton of Bamber Bridge, near Preston, opened the first print works in Lancashire.

After this, printing progressed at a remarkably rapid rate in England. The effects were obtained by impressing carved blocks smeared with thickened colour on to cloth until 1770, when Bell conceived the idea of printing calico in much the same way that engravings are produced on paper with engraved copper plates. The difficulty experienced in this method was to make successive impressions *join up* imperceptibly, and it has always been limited to handkerchiefs and designs made up of detached objects; this was overcome by the invention of the roller printing machine by Bell in 1783. In 1800 Ebinger invented a method of peg or surface printing, which was practically a block in the form of a cylinder. This was greatly improved upon by an Englishman, Burch of Accrington, who introduced the method of coppering (often employed in hand block printing), covering the rollers with varnish to protect them from damp and supplying them with a colour furnishing blanket. This method, with improvements, is adopted in the production of cheaper cretonnes with designs resembling those of hand block printing.

A combination of relief and intaglio printing is sometimes carried out. Watt in England and Depouilly in France were pioneers in the production of relief printing machines, but the most satisfactory block machine was constructed by Perrot of Rouen to print three colours. This is used to some extent in England but still more in France, Switzerland and Italy. In all countries roller printing is the most important method, but thick fabrics, such as cretonnes, heavy velvet and plush do not present the kind of surface which is well adapted to roller printing in heavy shades, and such material is block printed by hand. For the successful application of roller printing, the engraving of the copper cylinders is a most important matter. Every part of a design which is represented in a particular colour requires a separate roller, so that every new design which is introduced involves considerable expense for roller engraving. Various devices have been proposed for overcoming this difficulty, but they do not appear to find much application.

Printed fabrics are really locally dyed, but the applications of watery liquids to the surface of cloth results in blurred and indefinite outlines. Such effects are sometimes desirable, in which case *spray dyeing* is resorted to, with perhaps the most pleasing effects in the case of real silk material. Special machines (aerograph sprays) have been devised for this purpose. If clear, well defined outlines are required, it is necessary either to size the cloth or to thicken the colour solution. The first method was probably adopted in the early days of printing in England, and natural gums were used until the end of the 18th century.

The discovery of a satisfactory substitute for natural gum is said to have originated from a fire in a starch factory in Dublin early in the 19th century, the gummy material produced by the mixture of half burnt starch and water being tried at a print works and proved satisfactory. According to other accounts the discovery is attributed to Vauquelin and Bouillon-Lagrange. In any case British gum must have been discovered before 1815. It was found that it could be conveniently used as an addition to the colour instead of applying it to the cloth.

There are three methods of printing designs on textiles, viz., *Block printing*, using the hand block, or the perrotine machine, also peg or surface printing. *Intaglio printing*, the roller or cylinder machine being the only satisfactory device. *Surface printing by lithography*, using some special machines of limited application. In addition to these is stencilling (of considerable importance, especially for the application of metals to fabric), the drop and brush method and spraying.

METHODS OF PRINTING

Hand Blocks.—These are made of box, lime, holly, sycamore, plane or pear wood, but generally one of the last three. The blocks vary in area, but are always two or three inches thick and are backed with pieces of deal or pine, the grain of each adjacent piece running in a different direction. All are secured firmly together to prevent warping. When the surface of the block has been planed and rubbed level, the outline of the design is put on by applying a tracing in lamp black and oil to the surface and rubbing. The portions to be left in are tinted with ammoniacal carmine or magenta, the block is damped and the parts which are not required are cut away, commencing with the heavier masses and proceeding to the finer ones. The latter are sometimes cut on a separate block. Coppered blocks are used for fine work and these are made by inserting strips and pegs of brass or copper into the surface of the block. Burch of Accrington devised an instrument (fig. 1) for preparing blocks which closely resembles a drilling machine used by engineers, but in place of the drills, fixed punches (heated by a small gas blow-pipe or bunsen burner) can be raised or lowered by a foot lever, while the block is moved about by the worker. The heated punches

are sometimes made to revolve. Blocks are often felted or flocked so that more colour can be applied to the cloth, and this secures better penetration.

In addition to the engraved block, a stone printing table and a colour sieve are required Over the table top a woollen printer's blanket is tightly stretched. At one end, the table is provided with a couple of iron brackets to carry the roll of cloth, and, at the other, a series of guide rollers, extending to the ceiling, are arranged for the purpose of suspending and drying the newly printed goods. The colour sieve consists of a *swimming tub,* half filled with starch paste on the surface of which floats a frame, covered at the bottom with a tightly stretched piece of mackintosh or oiled calico. On this the colour sieve proper, a frame covered with fine woollen cloth, is placed, and forms, when in position, an elastic colour trough over the bottom of which the colour is spread evenly with a brush

FIG. 1.—FELTED BLOCK
The pitch pins should be fixed in the holes in the lower ends

The *modus operandi* of printing is as follows: The printer commences by drawing a length of cloth, from the roll, over the table, and marks it to indicate where the first impression of the block is to be applied. He then applies his block in two different directions to the colour on the sieve and finally presses it firmly and steadily on the cloth, ensuring a good impression by striking it smartly on the back with a wooden mallet. The succeeding impressions are made in the same way, continuity being ensured

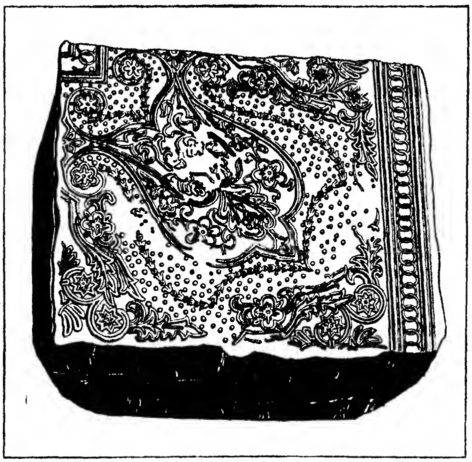

FIG. 2—COPPERED BLOCK SHOWS THE LAYERS OF WOOD WITH THE COPPER WIRE AND PEGS PRODUCING THE DESIGN IN THE TOP PIECE

by means of pins, at each corner of the block, which are arranged so that, when those at the right side or at the top of the block fall upon those at the left side or the bottom of the previous impression, two printings join up exactly and continue the pattern without a break. As each length is finished it is wound over the drying rollers, thus bringing forward a fresh length to be treated similarly. If the pattern contains several colours the cloth is usually first printed throughout with one, then dried, rewound and printed in turn with the others.

Many modifications of block-printing have been tried from time to time, but of these only two—"tobying" and "rainbowing"—are of any practical value. The object of "toby-printing" is to print the several colours of a multicolour pattern at one operation, and a block, with the whole of the pattern cut upon it, and a specially constructed colour sieve are employed. The latter consists of a thick block of wood, on one side of which a series of compartments are hollowed out, corresponding roughly in shape, size and position to the various objects cut on the block, and supplied with colour to correspond to the design.

The Perrotine.—Three blocks (3 ft by 3 ft.-5 in.), with the pattern cast on them in relief, are brought to bear successively on the three faces of a specially constructed printing table over which the cloth passes (together with its backing of printer's blanket) after each impression. The faces of the table are arranged at right angles to each other, and the blocks work in slides similarly placed, so that their engraved faces are perfectly parallel to the tables. Each block is provided with its own colour trough, distributing brush and woollen colour pad or sieve, and is supplied automatically with colour by these appliances during the time the machine is in motion. For certain classes of work the perrotine possesses great advantages over the handblock, for not only is the rate of production greatly increased, but the joining up of the various impressions to each other is much more exact, and no sign of a break in continuity of line is noticeable in well executed work. However, the perrotine can only be used for patterns containing not more than three colours and not exceeding 5 in. in vertical repeat, whereas hand block-printing can cope with patterns of almost any scale and containing any number of colours. The two processes, therefore, cannot be compared on the same basis; the perrotine is best for work of a utilitarian character and the handblock for decorative work in which the design only repeats every 15 to 20 in. and contains colours varying in number from one to a dozen.

Machines for peg or surface printing, as it is sometimes termed, are arranged much in the same way as intaglio printing machines, except that the peg or printing roller is cut in relief and the colour is served to it by means of a short endless colour blanket or sleeve which is supplied from colour furnishing rollers It is usually employed for rather large designs on cheap cretonnes and linoleum.

Roller Printing or Cylinder Printing.—The working of the machine is shown in fig. 3. A cast iron cylinder is mounted

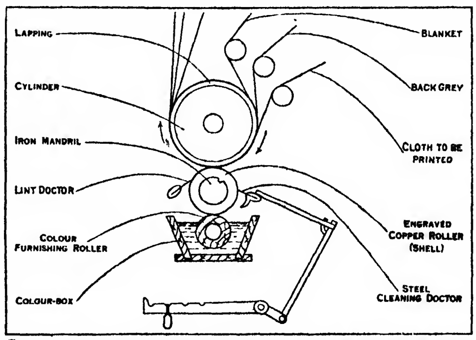

FIG. 3—DIAGRAM SHOWING WORKING PARTS OF ONE COLOUR PRINTING MACHINE

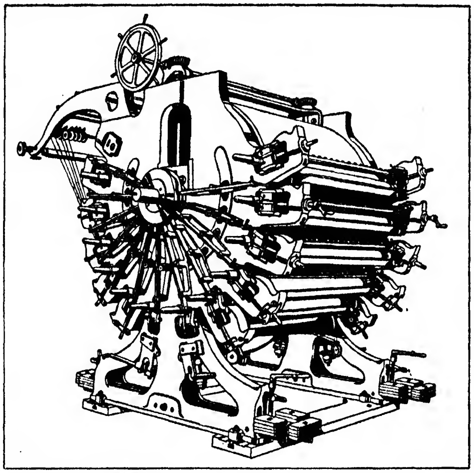
in adjustable bearings capable of sliding up and down slots in the sides of rigid iron framework. It is covered with several folds of lapping and a blanket of wool or rubber to give elasticity. Beneath is an engraved copper roller which is supplied with colour from a roller which revolves in a colour box below it. Two knives known as "doctors" rest against the engraved roller, one serving to remove colour from the smooth parts of the roller and known as the "cleaning doctor." It is pressed against the roller by means of levers. The other, made of brass, is the

"lint doctor" which removes loose filaments or lint which the roller picks up from the cloth.

In operation, the cylinder is screwed down with an even pressure into frictional contact with the roller below; the machine is then set in motion, turning in the direction indicated by the arrows; the cloth is now introduced between them and as it leaves the machine fully printed it is carried over a series of



BY COURTESY OF MATHER & PLATT

FIG. 4.—TWELVE COLOUR GARMENT PRINTING MACHINE

drying chambers situated above and heated by steam. The printing roller is the only part of the machine directly connected with the motor or main drive of the works through the cog-wheel on its axle—the "mandril"—all the other parts deriving their motion from it, either by friction as in the case of the cylinder or by a spur wheel as in that of the colour-furnishing roller. The mode of printing is almost self-evident; the roller revolving in the direction of the arrow takes colour from the "furnisher"; the excess is then scraped off by the "doctor" and, in continuing on its course, it comes in contact with the cloth which being pressed by the cylinder into the engraving abstracts the colour therefrom and of course receives an exact impression of the engraved pattern. The pressure may be applied either through the cylinder to the roller or from the engraved roller to the cylinder by compound levers.

Larger machines printing from two to 16 colours are precisely similar in principle to the above, but differ somewhat in detail and are naturally more complex and difficult to operate. In a 12 colour machine (fig. 4) for example, 12 copper rollers, each carrying one portion of the design, are arranged round a central pressure cylinder, or bowl, common to all, and each roller is driven by a common driving wheel, called the "crown" wheel, actuated, in most cases, by its own steam-engine or motor. The pressure is applied to the cylinder through the rollers which work in specially constructed bearings capable of the following movements: (1) Of being screwed up bodily until the rollers are lightly pressed against the central bowl; (2) of being moved to and fro sideways so that the rollers may be laterally adjusted; and (3) of being moved up or down for the purpose of adjusting the rollers in a vertical direction. Notwithstanding the great latitude of movement thus provided each roller is furnished with a "box-wheel," which serves the double purpose of connecting or gearing it to the driving wheel, and of affording a fine adjustment. Each roller is further furnished with its own colour-box and doctors.

In recent years many improvements and additions have been made in printing machines. Chief amongst these are those embodied in the "intermittent" and the "duplex" machines. In the former any or all of the rollers may be moved out of contact with the cylinder at will, and at certain intervals. Such machines are used in the printing of shawls and "saris" for the Indian market. The goods require a wide border right across, and it is to effect this, with rollers of ordinary dimensions, that "intermittent" machines are used. The body of the "saris" will be printed, say for six yards, with eight rollers; these then drop away from the cloth and others, which have up to then been out of action, immediately fall into contact and print a border or "crossbar" say one yard wide, across the piece; they then recede from the cloth and the first eight again return and print another six yards, and so on continually.

The "duplex" or "reversible" machine derives its name from the fact that it prints both sides of the cloth. It consists of two ordinary machines so combined that when the cloth passes, fully printed on one side from the first, its plain side is exposed to the rollers of the second, which prints an exact duplicate of the first impression upon it in such a way that both printings coincide. A pin pushed through the face of the cloth ought to protrude through the corresponding part of the design printed on the back if the two patterns are in good "fit."

Lithographic printing is employed with success in the printing of silk handkerchiefs. Haley's process is described in the 1915 *Journal of the Society of Dyers and Colourists*. In 1920 an Indian named Cooper proposed to avoid engraving rollers by using designs, cut in paper (stencils) or curtain net, on the bowl and placing the cloth between this and a uniform layer of colour on a roller beneath it. The arrangement was applicable when used with lithographic (oil) inks but was not so successful with calico printers' colours (starch or gum thickening). In 1926 A. Crompton obtained a patent for a machine with rollers arranged side by side but otherwise on a similar principle to that of Cooper and claimed it to be successful in calico printing.

In stencilling colour is brushed through holes cut in stout paper or metal. The Japanese are particularly successful in hand work of this kind for they can by tying parts of the designs with raw silk thread produce almost circular patterns. In England a machine for stencilling has been patented by S. H. Sharp.

Variegated and marbled effects, patented by the Calico Printers' Association, Ltd., E. Schofield and F. Farnworth, are obtained by applying colours to the underside of a horizontally travelling fabric by means of rotating brushes which dip into a colour box beneath, and to the upper side by allowing colour to drop on to the cloth from a series of colour cans provided with taps to regulate the rate of flow. Reversible effects can be obtained. The rollers are of smooth brass and travel at a higher speed than the cloth; they pick up the surplus colour and transfer it to doctors which carry it away to a suitable vessel. It may be utilized for a very wide range of styles.

Thickening Agents.—The thickening agents in most general use in printing are starch, flour, gum arabic, gum senegal and gum tragacanth, British gum or dextrine and albumen. With the exception of albumen all these are made into pastes, or dissolved by boiling in jacketed pans between the inner and outer casings of which either steam or water may be made to circulate. Mechanical agitators, fitted in these pans, are in action during boiling and cooling, to mix the various ingredients and to prevent the formation of lumps.

Starch paste is made by mixing 15 lb. of wheat starch with cold water to form a creamy paste; a little olive oil is then added and sufficient water to bring the whole up to 10 gallons. The mixture is thickened by being boiled for about an hour and, after cooling, is ready for use. It is the most extensively used of all the thickenings, and is applicable to all but strongly alkaline or strongly acid colours. With the former it thickens up to a stiff unworkable jelly, while mineral acids or acid salts convert it into dextrine, thus diminishing its thickening power. Acetic and formic acids have no action on it even at the boil. Flour paste is made in a similar way to starch paste. At the present time it is rarely used for anything but the thickening of aluminium and iron mordants, for which it is eminently adapted.

Gum arabic and gum senegal are both very old thickenings, but their expense prevents them from being used for any but delicate tints. They are specially useful thickenings for the light ground colours of soft muslins and sateens, on account of the property they possess of dissolving completely out of the fibres of the cloth in the washing process after printing. Starch and artificial gums always leave the cloth somewhat harsh unless they are treated specially and are incapable of yielding the clear and even tints resulting from the use of natural gums Very dark colours cannot well be obtained with gum senegal or gum arabic thickenings; they come away too much in washing, the gum apparently preventing them from combining fully with the fibres. Stock solutions of these two gums are usually made by dissolving 6 or 8 lb. of either in one gallon of water, either by boiling or by standing in the cold.

British gum or dextrine is prepared by heating starch It varies considerably in composition, sometimes being only slightly roasted and consequently only partly converted into dextrine, and at others almost completely soluble in cold water and very dark in colour. Its thickening power decreases and its gummy nature increases as the temperature at which it is roasted is raised. The lighter coloured gums or dextrines will make a good thickening with from 2 to 3 lb. of gum to one gallon of water, but the darkest require from 6 to 10 lb per gal to give a substantial paste, and are very useful for strongly acid colours, and, with the exception of gum senegal, are the best thickening agents for strongly alkaline colours and discharges Like the natural gums, neither light nor dark British gums penetrate into the fibre of the cloth so deeply as pure starch or flour, and are therefore unsuitable for very dark strong colours.

Gum tragacanth, or "Dragon" is one of the most indispensable thickening agents possessed by the textile printer It may be mixed in any proportion with starch or flour and is equally useful for pigment colours and mordant colours When added to starch paste it increases its penetrating power, adds to its softness without diminishing its thickness, makes it easier to wash out of the fabric and produces much more level colours than starch paste alone. Used by itself it is suitable for printing all kinds of dark grounds on goods which are required to retain their softness. A tragacanth mucilage may be made either by allowing it to stand a day or two in contact with cold water or by soaking it for 24 hours in warm water, and then boiling it up until it is smooth and homogeneous. If bottled under pressure it gives a very fine smooth mucilage (not a solution proper), much thinner than if it had been made in the cold.

Albumen is both a thickening and a fixing agent for insoluble pigments such as chrome yellow, the ochres, vermilion and ultramarine. Albumen is always dissolved in the cold, a process which takes several days when large quantities are required The usual strength of the solution is 4 lb per gal of water for blood albumen, and 6 lb. per gal for egg albumen The latter is expensive and only used for the lightest shades For most purposes one part of albumen solution is mixed with one part of tragacanth mucilage, this proportion of albumen being found amply sufficient for the fixation of all ordinary pigment colours In special instances the blood albumen solution is made as strong as 50% but this is only in cases where very dark colours are required to be fast to washing After printing, albumen-thickened colours are exposed to hot steam which coagulates the albumen and effectually fixes the colours

Concentrated solutions of the colouring matters and other adjuncts are added to the cold thickenings, of which large quantities are kept in stock Colours are reduced in shade by simply adding more starch or other paste For example, a dark blue containing 4 oz. of methylene blue per gal may readily be made into a pale shade by adding to it 30 times its bulk of starch paste or gum, as the case may be. Similarly with other colours. Before printing it is very essential to strain or sieve all colours in order to free them from lumps, fine sand, etc., which would inevitably damage the polished surface of the engraved rollers and result in bad printing, since every scratch on the surface of a roller prints a fine line in the cloth The straining is usually done by squeezing the colour through fine cotton or silk cloths. Mechanical means are also employed for colours that are used hot or are very strongly alkaline or acid

STYLES OF PRINTING

The designation of any particular style of printing is based on its method of production. There is a large number of these recognized technically and it frequently happens that a multicoloured effect involves more than one style of work, but in such a case it is usual to apply the name of the predominating style to the whole. Styles may be grouped under the following headings:—Direct printing (many colours for which special methods have been devised and are frequently classed under special groups, for example para red or insoluble azo style can be applied directly in printing); dyed style; discharge style; resist printing; processes of producing differences of texture or lustre in the textile fabrics either with or without colouring.

Direct Printing.—This style is largely used and can be applied with almost all types of colouring matters, if suitable ingredients are chosen which will react, in steaming, to produce colour lakes fixed on the fibre In this way very fast effects can be produced, for this style of printing differs entirely from dyeing with direct cotton colours which are seldom used in cotton printing. The *mordant colours,* applied with a salt of alumina (frequently the acetate or the sulphocyanide), iron, or chromium, together with thickening and acetic acid, give bright and full shades of good fastness

For alizarine red of full brilliance it is necessary to add a little oxalate of tin and lime, together with a little acetic, tartaric or oxalic acid, to obtain the brightest shades. In most cases, too, it is preferable to treat the cloth before printing with an oil "prepare" which consists of 50 parts ricinoleic acid, 20 parts ammonia, 20 parts sodium carbonate made up together to 1,000 parts After printing, the goods are steamed and the colour is fixed When utilized for the fixation of mordant colours this is sometimes known as the "extract style" because it was originally used in the case of madder, logwood and quercitron bark extracts For printing alizarine red the following printing paste (made up in parts by weight) may be applied to cloth treated with oil prepare — 47 parts water, 13 starch, 13 alizarine (20% paste), 3 acetic acid 9° Tw Boil, turn off the steam and add 2 5 chlor oil (made by mixing equal parts of olive oil and 7° Tw bleaching powder solution to form an emulsion), 2 5 stannic hydrate 20% paste, 2·5 oxalate of tin. Cool, and immediately before use add cold 3·5 acetate of lime 23° Tw, 4 nitrate of alumina, 23° Tw and 10 sulphocyanide of alumina 20° Tw. If it is desirable to print cloth which has not been previously oiled (*e g*, when aniline black is to be printed side by side with alizarine) a special emulsion may be made with sulphoricinoleic acid, gum tragacanth and acetic acid There is then no danger of the black being spoiled by the alkali in the oil prepare

Alizarine blue and green give good shades with chromium acetate as mordant:—½ lb alizarine blue (powd) (light shade), 1 gal water, 3½ gal. thick paste, 1½ gal acetate of chrome 40° Tw

Logwood and other natural colours are specially boiled. For logwood black—15 lb. starch, 10 lb British gum, 4½ gal. water, ¾ gal acetic acid, 1½ gal. logwood extract, 48° Tw., ⅜ gal quercitron extract, 48° Tw. Boil, cool and add.—½ lb. red prussiate of potash, ¼ gal water, 2 gal. acetate of chrome, 40° Tw., 2 oz. chlorate of potash.

Indigoid Colours.—There are three methods of printing indigo blue: The glucose or Schlieper and Baum process; the hydrosulphite process; and by the utilization of already reduced compounds such as indigosol and soledon colours.

In the first method the cloth is first prepared with glucose (300 parts grape sugar to 700 water) dried and then printed with 150 indigo (20%) and 850 alkaline thickening (made by mixing 30 maize starch, 100 dark British gum and 870 caustic soda 77° Tw.). The goods are steamed as quickly as possible after printing by running for ½ min. through an ager at 100° C (moist steam). They should then appear a brownish olive colour in the printed parts, and are exposed to the air, washed in running water, treated with 1° Tw. sulphuric acid, and again washed. Light

shades of indigo can be oxidized by exposing to the air. This is perhaps the cheapest way of printing indigo and the colour is in no way inferior to that produced by the second method. The hydrosulphite process overcomes the necessity of preparing the cloth, for in this process indigo is printed in admixture with hydrosulphite formaldehyde. This compound dissociates in steaming, the hydrosulphite reduces the indigo and the cloth is locally dyed. The goods are then "aged" and allowed to lie a short time, after which they are washed in cold water first, until the indigo is thoroughly re-oxidized, and then in hot water or soap. The composition of this printing colour is as follows:—200 parts hydrosulphite N.F. (or 100 of the concentrated product), 450 parts alkaline dextrine paste, 150 parts indigo 20% paste (ground up in gum), 200 parts alkaline dextrine paste. Thickening—150 parts dextrine or British gum and 850 parts caustic soda, 70° Tw.

Indigosol O is printed in admixture with gum tragacanth thickening and sodium nitrate, being afterwards developed by passing through a bath containing hot formic or oxalic acid; in some instances hot acetic acid may be used. Thus 100 parts indigosol O, 350 parts hot water and 550 parts tragacanth thickening and 30 parts sodium nitrate is printed on to cotton fabric, which is then dried in hot air. Blue is developed by treating for a few seconds at about 80° C in a bath containing 4 parts formic acid (90%), 8 parts common salt and 100 parts water. The Soledon products and other indigosols may be applied in a somewhat similar way. As these materials can be used in conjunction or juxtaposition with colouring matters of totally different groups (both as regards dyeing and chemical constitution), such as insoluble azo colours and aniline black, they are especially useful. Rowe and Bean (1927) have given valuable information with regard to the development of the indigosols and allied products with different oxidizing agents.

Other Vat Colours.—Indanthrene, duranthrene, caledon and cibanone colours as well as those of the algol and alizarine indigo series may be applied by methods analogous to those described for indigo. Some very fast effects may be obtained, but difficulty is experienced by printers, owing to the fact that if the backgreys become stained with the colours, it is almost impossible to bleach them. This is a serious matter if customers' cloth is used for backgrey. Some of these colours require much alkali for their fixation and this is liable to attack the blanket. A steaming method for the printing of these colours which gives satisfactory results is the following:—600 parts alkaline thickening (a mixture of British gum and gum senegal), 100 colouring matter, 80 stannous oxide 50% paste, and 50 glycerine. Hydrosulphite formaldehyde may be used in place of stannous oxide as the reducing agent. Duranthrene yellow and cibanone blue 3G are colours suitable for printing in this way. After the goods have been steamed and the colour fully developed it is best to wash out the alkali from the cloth as thoroughly as possible. Sulphur colours and sulphurized vat colours are best printed with hydrosulphite formaldehyde.

Aniline Black.—Various methods for the oxidation of *aniline*, but particularly the prussiate method described under DYEING, may be utilized in printing. All are difficult to print well. Some difficulty is experienced in steaming or ageing, and special ageing appliances, with suction elements to carry away acid vapours and to maintain a relatively pure atmosphere of steam, have been patented. From the same source patents, in which the amount of acid used in the formation of the black is reduced to a minimum, figure conspicuously. The following is an ungreenable black which requires no afterchroming: 7·5 parts starch, 300 gum tragacanth mucilage, 32 aniline, 44 aniline salt, 4.5 paraphenylene diamine dihydrochloride, 40 formic acid (90%) 34 boracic acid, 41 chlorate of soda, 40 copper sulphide (24%). Print this mixture on to the cloth, age, wash and soap. The ageing process is carried out in an apparatus fitted with suction elements between the layers of cloth.

Basic Colours are of importance where brightness is the most important consideration. The usual method is to add the dyestuff to the prepared thickening, then some acetic, citric or tartaric acid, and then a mixture of tannic acid and acetic acid; *e.g.*, 20 parts methylene blue, 50 acetic acid (40%) 120 water and 720 starch paste are heated together, 10 ground tartaric acid cooled, and 80 tannic acetic solution (50%) are added. After printing the cloth is steamed.

Insoluble Azo Colours may be employed in a variety of ways, the most important being: (*a*) Printing a pattern in thickened naphthol and afterwards passing through a diazo solution. (*b*) Printing a diazo solution on cloth prepared in various naphthols. In these processes procedure is much the same as in DYEING (*q.v.*), except that in (*a*) the naphthol is thickened with British gum and in (*b*) the diazo solution is thickened with gum tragacanth. Various naphthols may be used and a large variety of shades obtained by utilizing naphthol A.S. and allied products. A good black can be obtained with A.S., S.W. and fast black base L.B. The colours possess great fastness and are but little affected by hot ironing (a defect of the beta naphthol colours). The latter such as para red and alpha naphthylamine maroon are used for cheap work. (*c*) The *rapid fast colours* (stabilized diazo compounds or nitrosamines mixed with analido compounds of beta oxynaphthoic acid) can be applied directly in printing. They are rather expensive but find considerable application because they are readily developed by treating the cloth after printing with hot dilute acetic acid. It is necessary to add a little potassium chromate to the printing colour if these are printed in combination with basic or chrome colours. They are conveniently used in combination with indigosols or Soledon colours. Everest has shown (1928) that the naphthols may be applied to silk from a soap bath and in the absence of caustic alkali. The method is patented for silk printing.

Application of Pigment Colours.—Before the introduction of coal-tar colours, pigments and lakes played a more important part in textile printing and they are still largely used for certain styles of work. They form a series of colours more difficult to work than those already mentioned, but very fast to soap and light. Pigment colours, being insoluble mineral precipitates or lakes, can only be fixed on the fibre mechanically; consequently they require to be applied in conjunction with vehicles which cause them to adhere to the fabric in much the same way that paint adheres to wood. Of these vehicles, albumen is the most important and the best. It forms a smooth viscous solution with cold water, mixes readily with all the colours used in pigment printing, and possesses the property of coagulating when heated to the temperature of boiling water. When cloth printed with colours containing albumen is passed through hot steam or hot acid solutions, as in the indigo discharge style, the albumen coagulates, forming a tough insoluble colloidal deposit, which firmly fixes on the fibre any colour with which it is mixed.

The colours chiefly employed in pigment printing are: chrome yellow and orange, Guignet's green or chrome green, artificial ultramarine, lamp black for greys, the various ochres for golds and browns, zinc oxide, vermilion and its substitutes, and occasionally lakes of the natural and artificial colouring matters.

Dyed Style.—Before the introduction of the azoic colours of the naphthol A.S. series, practically the only reliable method of obtaining fast shades in printing was by printing mordants on to cotton and then dyeing in natural colours such as madder, persian berries, logwood and other dyewoods. Alizarine has entirely superseded madder but logwood and persian berries are sometimes used. Other alizarine and chrome colours may be dealt with in this way. The application of the mordant in printing involves (1) the preliminary preparation of the cloth with oil, (2) printing on the mordant usually in the form of acetate, (3) ageing, (4) fixing (dunging is said to be more efficient than substituted fixing agents because it removes thickening material as well as excess of mordant) and (5) dyeing (*see* DYEING) in alizarine. In order to obtain perfect white in the unprinted portions, cloth after washing and soaping is passed through a very dilute solution of bleaching liquor. The process has been mainly used for obtaining red, pink, lilac and black prints, by depositing varying strengths of alumina and iron and dyeing in alizarine and logwood.

The thickened mordants used in the madder style are called colours, not because they contain any colouring matter, but because they give definite shades when dyed in alizarine. For madder red the following method applies:—6T Red. 100 parts wheat

starch, 50 parts flour, 900 parts red liquor 6° Tw. (from which the red acquires its designation), 20 parts olive oil and 0·5 parts magenta (to sight the mordant). The goods are then passed at full width through a fly dunging machine containing 500 gal. water, 15 parts chalk, 2½ parts phosphate of soda and 70–85 parts cow dung.

A second dunging is carried out in a vessel similar to a dye beck and the goods are worked for 20–30 min. at 50–60° C. Malt or bran added to the dunging liquor accelerate the removal of starch but this is more necessary when using one of the substitutes for dung, *i e*, phosphate of soda (1½–6 parts by weight), binarsenate of soda (2–5 parts), or silicate of soda 32° Tw. (20 parts), with 7·5 parts of chalk per 1,000 parts water. After fixing, the goods are washed and dyed in 5% alizarine (20% paste) with the addition of Turkey red oil 5% and 0·5% chalk. Soaping and clearing completes the process.

The following table gives the ingredients necessary for obtaining six colours by printing the mordants on one piece and afterwards dyeing in a single bath with 4·5% alizarine (20% paste) and acetate of lime, proceeding as before. Aniline black may be printed along with red and black liquors. It is usual to employ only one or two colours, in this style of printing, with perhaps two concentrations of red or black liquor for light and dark shades of red and purple

effects and white. With two rollers the following four colours can be obtained on a light indigo blue: blue; green, by overprinting indanthrene yellow; white, by discharging parts of the blue; and yellow, by applying the discharge on parts coloured green. Azo colours resist the action of bichromate and can be used in this style of printing by incorporating mixtures for their production with the chromate printing discharge for blue.

As compared with oxidation discharges (chromate and chlorate) the *Leucotrope hydrosulphite discharge* possesses a great advantage in that the darkest shades of indigo can be discharged to a pure white without any danger of tendering the cloth. Hydrosulphite is the reducing agent for the indigo, but the leucotrope forms either a means of removing indigo white from the fibre (Leucotrope W. forms an alkali soluble yellow compound with indigo white) or a means of producing coloured discharges (Leucotrope O. forms a yellow compound which is not removed by washing in alkali) Examples:—

Strong Discharge White· 160 parts zinc oxide (50% paste), 100 parts Leucotrope W., 240 parts hydrosulphite formaldehyde, 40 parts anthraquinone (30% and paste), 460 parts British gum thickening

Yellow Discharge: 460 parts British gum thickening, and 200 parts hydrosulphite formaldehyde, dissolve, cool and add 100 parts Leucotrope O , 40 parts anthraquinone (30% paste) and 200 parts

Ingredients	Red	Pink	Chocolate	Dk purples	Violet	Black
Aluminium acetate, 6° Tw	12 gal	3 gal	10½ gal			
Black liquor, 24° Tw.	.		1½ ,,	1 gal	½ gal.	8 gal.
Water		8 gal		11 ,,	11½ ,,	4 ,,
British gum	..	36 lb.			36 lb	..
Acetic acid		1 gal				..
Tin crystals	1½ lb.	¾ lb.			.	..
Cotton-seed oil.	¼ gal.		¼ gal	¼ gal.	.	¼ gal.
Starch	16 lb.		16 lb	16 lb		16 lb

Discharge Printing.—This depends upon the action of acids, alkalis, oxidizing and reducing agents for the destruction of dyed colours. It stands to reason that colours which are very fast require drastic oxidizing or reducing agents for their decomposition, but the former are difficult to apply without danger to the printed fabric. Sometimes two reagents play a part in the process. One is printed on the dyed fabric and reacts with the second, through a solution of which the printed fabric is passed An advantage of this method is that fine delicate patterns can be discharged on a dark ground with a crispness of definition which is difficult to attain with a blotch roller.

Iron and *alumina mordants* are discharged by printing with citric acid, so that a white pattern on a coloured ground is obtained on dyeing *Basic colours* are destroyed with alkalis. The *chrome discharge* is produced by printing the goods with a solution of sodium or potassium bichromate thickened with British gum, passing through a mixture of oxalic acid and sulphuric acid White and coloured discharges on indigoid colours are obtained in this way.

Chromate Discharge.—White. 8½ gal. British gum paste, 12 lb. bichromate of soda and ½ gal turpentine (prevents frothing)

Yellow: 32 lb. chrome yellow pigment, 3 gal 50% albumen solution, ½ gal. thick tragacanth mucilage, and ¼ gal oil (vegetable), 12 lb. bichromate of soda neutralized with ¾ gal caustic soda, 70° Tw, and ½ gal water

Print, dry, pass through a "beck" (*i e*, a bath) containing: 100 gal. water, 50 lb. sulphuric acid (168° Tw.), and 50 lb oxalic acid, then wash well and dry.

A green discharge is obtained with Guinet's green, a red with vermilion and brown with burnt sienna in place of chrome yellow. These colours resist the action of the bichromate and the acid treatment which follows printing coagulates the albumen. Another method (Freyberger) consists in printing on a thickened solution of sodium nitrate and, after drying, running through sulphuric acid of 50° Tw.

With colours of the indanthrene series, indigo gives compound shades and, as these are not destroyed by bichromate, over printing this with a roller of another pattern produces three colour

zinc oxide (50% paste) Glucose may be used as the reducing agent for discharging indigoid colours. This is especially useful in producing coloured discharges with insoluble azo colours. Leucotrope cannot be used with indanthrene colours as it acts as an efficient resist to their fixation.

Resist Style.—In the resist style, dyeing is prevented (1) by the application of substances which mechanically protect the fibre from contact with the dyestuff or (2) by the action of substances which act chemically either by decomposing the dyeing material or preventing its formation.

A very ancient method of ornamenting fabric is what is known as the *batik style* (*see* BATIK and TEXTILES). Imitations of this style are obtained by printing wax from engraved roller plates and stencils. Different colouring is obtained by putting on another pattern or part of a pattern in wax and redyeing. When the madder style is used for the colouring, the wax printed goods are mordanted and then dyed, the wax resist is broken, the cloth is dipped in the indigo vat, and a red, white, blue and chocolate effect is obtained, the latter by the superposition of blue on red By tinting the cloth in chrysamine (direct cotton colour) a buff instead of white is obtained.

In machine printing resin is used in place of wax: for this purpose rollers heated with an internal electric heater have been patented by F. Ashton and the Calico Printers' Association Resin-printed cloth fixes chromium from hydrosulphite formaldehyde mixtures instead of resisting it. Bichromate of soda and formosul are the best for this purpose. If resin-printed cloth is dyed in indigo before mordanting, the batik cracks appear in light blue on a dark ground, the shade of the ground being slightly modified by the superposed mordant colour. Other white resists are obtained by printing metallic salts, flowers of sulphur and lactic acid, or ammonium nitrate under the ordinary printing resists. The composition of the best resist for indigo printed by the glucose process is as follows: 150 parts flowers of sulphur, 50 parts lactic acid 50%, and 800 parts 30% gum Senegal solution.

Sulphur is liable to etch the roller immediately following the resist roller, and this may be avoided by the use of chemical resists (Reserve Salts W and O, Kalle and Co.), which however do

not give good results if crushed by the next roller, so can only be used with advantage for single colour resists. Indigosols can be used with success in resist printing. Leucotrope (150 parts Leucotrope O. 850 British gum thickening) will prevent the fixation of any vat dye printed over it.

Resists Under Aluminium and Iron Mordants.—For the production of this important class of goods, use is made of the fact that alkaline citrates prevent the fixation of the mordants. The cloth is first printed with citrate of soda (or sometimes citric and tartaric acids for iron mordants), then dried, and again printed over the previous impression, with either a fine "all over" pattern or flat uniform ground, in iron or aluminium mordants. The fabric is then aged, dunged, washed and dyed as already described, with the result that, wherever the "reserve" of citrate or acid was printed, a white pattern is left on a figured or plain ground. The fine patterns printed over "resists" are called "covers" and the plain grounds "pads," hence the name cover and pad style in cases where, as frequently happens, a dark cover and a light pad are both printed over a white resist. The cover and pad style is, for the most part, restricted to dyed alizarine purples, under which red, black, dark purple and white can all be resisted at the same time, thus giving rise to very pleasing effects.

In the case of resists under steam, alizarine red, and pink, a reserve composed of citrate of chromium alone, or in conjunction with citrate of soda, gives the best results. The goods are first prepared in alizarine oil and then printed with the following: 10 lb. china clay, ½ gal. citrate of soda, 54° Tw., ½ gal. citrate of chromium, 42° Tw., ½ gal. water, and 2½ gal. British gum paste. After printing the above, the goods are dried, again printed either with cover or pad or both in alizarine pink, dried, steamed for 1½ hr., well washed and soaped. On leaving the steamer the parts printed with the resist are yellow, but become quite white on soaping. Like the purples, the alizarine pinks can be reserved in colours. For blue, green, yellow and violet the ordinary steam basic colours are used with additions of citric or tartaric acid; *e.g.*, 7 lb. china clay, ½ gal. water, 6½ gal. British gum paste, 2 lb. methylene blue, 1 lb. citric acid and 1 gal. acetic acid. Boil, cool and add 1½ gal. 50% tannic acid solution in acetic acid. The *resisting* of *aniline black* is effected by the use of alkalis, which, as Prud'homme discovered, prevent the formation of the colour. White and coloured resists may be applied either before the liquor is padded with the prussiate black liquor or after padding, in which case it is often termed a *discharge black*. The black is developed except where the resist (discharge) has been printed. For the true resist process it is essential that the printing mixture shall contain some insoluble plastic material, such as zinc oxide.

Variations.—Variations in the appearance and properties of portions of textile fabrics are frequently brought about by printing. A *crimped surface* on cotton fabric may be obtained either by printing caustic soda (60–70° Tw.) thickened with British gum, then washing; or by printing a very strong thickening on to the cloth and then passing the whole piece through a solution of 60° Tw. caustic soda and washing. In the first case the printed parts shrink, and so make the rest appear crimped; and in the second case, the printed parts, being protected from the action of the alkali, are caused to appear crimped by the shrinking of other parts of the material. These effects are usually applied in the form of stipes which is the best pattern for showing the effect to advantage. It is an adaptation of mercerizing.

Matt, lustring and delustring effects on fabrics composed wholely or partly of artificial silk of various kinds is carried out to a large extent. F. Scholefield produces an effect which closely resembles wool and silk by printing sodium sulphite, or other desulphurizing agent, on to a fabric composed of viscose silk containing sulphur (unbleached viscose). The latter, when spun in a suitable form, looks somewhat like wool and feels warm, but wherever it is desulphured the lustre of silk appears. Alternatively, if the sulphur yarn, of which the piece is composed, is fine and smooth it shows an opalescent lustre, while the delustred portions have a bright silk-like lustre. The lustre of acetate silk is altered by steaming alone. If protective agents in the form of organic acids are printed on to a piece of such artificial silk and it is then steamed, the lustre of the unprotected portions is reduced or lost while that of acid printed portions remains unimpaired. In nearly all cases of which these effects are typical, it is possible to combine the lustring and delustring style with one or more of the other styles of printing. In a very simple way effects of a novel character are obtained; for example, a piece of sateen, composed of cotton warp and acetate silk weft, is printed in fine check pattern with caustic soda, below mercerizing strength but still sufficiently strong to impart some modification in the dyeing property of the fibres. It is then dyed in one bath with a mixture containing a cotton blue and golden yellow for acetate silk. On one side the cloth appears almost as if it were composed of threads of metallic gold woven so as to show a transparent and shot dark and light blue background; on the reverse side the cloth appears mainly dark and light blue check, shot or intercepted with some gold threads. Warp printing is utilized to a considerable extent for the production of cretonnes, and other heavy weight fabric, for by this means it is easy to get good colour penetration like that obtained in dyeing. Holden (Nov. 1928) has obtained increased dyeing with direct colours and indigosols by printing cloth (velvet) with gelatine and then steaming.

Before cotton goods can be printed it is necessary that the cloth shall be thoroughly well bleached, and that all nap shall be removed from the surface by singeing and shearing. Especially if good whites are desired, or printing is done with fine stipple rollers (rollers engraved with dots instead of fine lines), the cloth must also be straightened on stenters and weft straighteners before it is printed, in order to show the pattern in proper position and register. Woollen goods are chlorinated before printing, for only comparatively mild steaming with moist steam is possible for this material. Silk is treated with stannous chloride or phosphate. Animal fibres take colours readily enough, after proper preparation, and not only wool, direct cotton, basic and mordant colours may be used, but also aniline black, nitroso blue and insoluble azo colours.

For complete directions for the printing of fabrics of both animal and vegetable origin, *see* E. Knecht and J. B. Fothergill, *Principles and Practice of Textile Printing* (2nd ed.). (E. Hı.)

ART AND ARCHAEOLOGY

Printing patterns on textiles, whether of flax, cotton or silk, by means of incised wooden blocks, is so closely related in its ornamental effects to other different methods of similar intention, such as by painting and by processes of dyeing and weaving, that it is almost impossible to determine from the picturesque indications afforded by ancient records and writings of pre-Christian, classical or even mediaeval times, how far, if at all, allusion is being made in them to this particular process. Hence its original invention must probably remain a matter of inference only.

Whilst the earlier history of stamping patterns by hand on to textiles in the East has still to be written, a serious attempt has been made to account for the existence of this decorative process in Europe during several centuries prior to the introduction of the "Indiennes" or printed and painted calicoes imported from the East. Specimens of printed stuffs have of recent years been obtained from disused cemeteries in Upper Egypt (Akhmîm and elsewhere) and tell us of Egypto-Roman use of such things. Some few of them are now lodged in European museums. For indications that earlier Egyptians, Greeks and Romans were likely to have been acquainted with the process, one has to rely upon less certain evidence. Of textiles painted by Egyptians there are many actual examples. Apart from these there are wall paintings, *e.g.*, those of Beni Hassan—about 2100 B.C.—in which are represented certain Asiatic people wearing costumes irregularly patterned with spots, stripes and zig-zags, which may have been more readily stamped than embroidered or woven. A rather more complicated and orderly pattern well suited to stamping occurs in a painting about 1320 B.C., of Hathor and King Meneptha I. Herodotus, referring to the garments of inhabitants of the Caucasus, says that representations of various animals were dyed into them so

as to be irremovable by washing. Pliny describes "a very remarkable process employed in Egypt for the colouring of tissues. After pressing the material, which is white at first, they saturate it, not with colours, but with mordants that are calculated to absorb colour." When this was finished the cloth was "plunged into a cauldron of boiling dye" and "removed the next moment fully coloured." "It is a singular fact, too, that although the dye in the pan is of one uniform colour, the material when taken out of it is of various colours according to the nature of the mordants that have been respectively applied to it." Egypto-Roman bits of printed stuffs from Akhīm exhibit the use, some 300 years later than the time of Pliny, of boldly cut blocks for stamping figure-subjects and patterns on to textiles. Almost concurrent with their discovery was that of a fragment of printed cotton at Arles in the grave of St. Caesarius, who was bishop there about A.D. 542. Equal in archaeological value are similar fragments found in an ancient tomb at Quedlinburg. These, however, are of comparatively simple patterns. Other later specimens establish the fact that more important pattern-printing on textiles had become a developed industry in parts of Europe towards the end of the 12th and the beginning of the 13th century.

The Rhenish Monks.—According to Forrer (*Die Kunst des Zeugdrucks,* 1898) mediaeval Rhenish monasteries were the cradles of the artistic craft of ornamental stamp or block cutting. In rare monastic mss. earlier in date than the 13th century, initial letters (especially those that recurred frequently) were sometimes stamped from hand-cut blocks; and German deeds of the 14th century bear names of block cutters and textile stampers as those of witnesses. Between the 11th and 14th centuries there was apparently in Germany no such weaving of rich ornamental stuffs as that carried on in Spain and Italy, but her competitive and commercial instincts led her to adapt her art of stamping to the decoration of coarse textiles, and thus to produce rather rough imitations of patterns woven in the Saracenic, Byzantine and Italian silks and brocades. Amongst the more ancient relics of Rhenish printed textiles are some of thin silken stuff, impressed with rude and simplified versions of such patterns in gold and silver foil. Of these, and of a considerable number of later variously dyed stout linens with patterns printed in dark tones or in black, specimens have been collected from reliquaries, tombs and old churches. From these several bits of evidence Dr Forrer propounds an opinion that the printing of patterns on textiles as carried on in several Rhenish towns preceded that of printing on paper. He proceeds to show that from after the 14th century increasing luxury and prosperity promoted a freer use of woven and embroidered stuffs, in consequence of which textile printing fell into neglect, and only three centuries later it revived.

Augsburg, famous in the 17th century for its printing on linens, etc., supplied Alsace and Switzerland with many craftsmen in this process. After the revocation of the edict of Nantes, French refugees took part in starting manufactories of both painted and printed cloths in Holland, England and Switzerland; some few of the refugees were allowed back into France to do the same in Normandy; manufactories were also set up in Paris, Marseille, Nantes and Angers; but there was still greater activity at Geneva, Neuchâtel, Zürich, St. Gall and Basle. The first textile-printing works in Great Britain are said to have been begun towards the end of the 17th century by a Frenchman on the banks of the Thames near Richmond, and soon afterwards a more considerable factory was established at Bromley Hall in Essex; many others were opened in Surrey early in the 18th century. At Mulhouse the enterprise of Koechlin, Schmatzer and Dollfus in 1746, as well as that of Oberkampf at Jouy, led to a still wider spread of the industry in Alsace. In almost every place in Europe where it was taken up and followed, it was met by local and national prohibitions or trade protective regulations and acts, which, however, were gradually overcome.

Invention of Roller Printing.—Towards the end of the 18th century a revolution in the British manufacture of printed textiles was brought about through the invention of cylinder or roller printing from metal plates. This is usually credited to Oberkampf of Jouy, but it seems to have occurred also to a Scotsman named Bell, and was successfully applied in a large way about 1785 at Monsey near Preston. From this and the calico-printing works at Manchester in 1763, and in Scotland in 1768, the present huge proportions of the industry in Great Britain have been developed.

Illustrations accompanying this brief account merely indicate a few types of patterns used in various European countries up to the beginning of the 19th century. Typical specimens of East Indian painted and printed calicoes for coverlets and other draperies are shown in the Indian division of the Victoria and Albert Museum. These are *sui generis,* and therefore differ from the bulk of Western prints on chintz, cretonne, etc., which together with a less quantity of printing on satin, silk, velvet, crêpe and the like are principally from adaptations of weaving patterns. An interesting series of over 2,500 patterns, chiefly of this character, was made by M. Corimand between 1846 and 1860, and is preserved in the National Art Library at South Kensington. For many years of the latter part of the 19th century, William Morris designed and produced attractively ingenious floral and bird patterns, admirable in contrasts of bright colours, frequently basing his arrangement of crisply defined forms in them upon that of Persian surface ornament.

BIBLIOGRAPHY.—J. Persoz, *L'Impression des Tissus* (Paris, 1846, *see* vol. i., preface); E. A. Parnell, *Dyeing and Calico Printing* (London, 1849); W. Crookes, F.R.S., *Dyeing and Calico Printing* (London, 1864, *see* introduction); Dr R. Forrer, *Die Kunst des Zeugdrucks* (Strasbourg, 1898). (A. S. C.)
